encouragement, and with appreciation
for their individual accomplishments.

"En tierra de los ciegos el tuerto es rey."

SPANISH PROVERB
I am very pleased to present the third edition of The 5-Minute Urology Consult. The first edition was released almost 15 years ago, with the second edition published in 2010. The continuing advances in urology lead to this much-needed 2015 update. The goal of this book is to provide the reader with useful information in a quick reference format to help with the everyday care of patients with urologic problems. This third edition has undergone extensive editing and updating to reflect the most current data possible at the time of publication.

Urologic diseases and conditions are common problems seen by all health care providers. Almost one-third of all genitourinary disorders involve the genitourinary system, and the urinary tract accounts for almost 25% of all solid tumors in adults. While this book is written primarily for urologists, any health care practitioner who deals with urologic complaints and conditions should find the book a useful resource. Students of urology, residents and fellows preparing for oral and written in-service examination, and practicing urologists preparing for certification examinations will find the book a useful study aid. While primarily written for practitioners in the United States, the table of contents has been reviewed by our international editorial board, which represent more than three dozen countries, in an attempt to capture as many diseases and conditions as possible for international readers.

The broad array of topics addressed in this book is based on reviews of published literature, major textbooks, grand rounds case presentations, validated Internet resources, and actual patient consultations. Topics are meant to represent “real-world” clinical questions from very broad to very specific topics. Some of the topics may appear redundant, such as Section I topics “Scrotum and testicle, masses” and “Scrotum, tumor and mass, adult, general considerations.” There is a deliberate reason for this, namely, to frame the thought process to differentiate scrotal masses from testicular masses when the presenting problem is not clear. If it is clearly a testicular mass, then the one topic deals effectively with that setting. If it is not a clear mass in the testicle, the reader can approach the problem more broadly in terms of a mass within the scrotum that may or may not involve the testicle. Coverage includes adult and pediatric urologic, as well as subspecialty areas of urology such as urologic oncology, endourology, female urology, neurourology, andrology, infectious diseases, and renal transplantation. It represents a core of essential “must-know” and practical information specifically written for the field of urology. While some surgical techniques are discussed, this is not meant to be a comprehensive urologic surgical text. Numerous high-quality publications address the finer points of urologic surgery. This book addresses pre and post operative care as well as some intra-operative techniques; however the focus is on more global patient management issues.

I am often surprised when asked why medical books such as this are even necessary as a reference in the modern world because there is so much information readily available on devices such as smartphones via the Internet. While the reality is that virtually any topic can be searched for on the Internet, the ability to sort through the information presented, confirm the validity, and rapidly find the specific information needed is often very time-consuming and can be prone to error. Multiple studies have shown that many websites can contain erroneous, misleading, or out-of-date information. Readers of this book can be assured that the information presented is held to the highest standards possible, as it is written, reviewed, and further edited primarily by academic urologists and other academic specialists. Every effort is made to present the most up-to-date standards of care at the time of publication.

This book, a member of the popular “5-Minute Consult” series published by Wolters Kluwer Health, generally follows the organizational formatting of the other books in the series. However, there are notable exceptions, as this book is focused on a primarily surgical subspecialty. Section I: Urologic Diseases and Conditions provides information on more than 300 major topics in the field of urology. The style of this section, while similar to the other books in the series, focuses more attention on the surgical management, where appropriate. Furthermore, evidence-based medicine references, standard fare in the “5-Minute Consult” series, are included in this urology edition. This is representative of the trend in the field of medicine to assign “levels of evidence” to treatment recommendations (see page ix for a further discussion). A challenge with any surgical discipline is that, when reviewing published literature, this type of information is not as well represented as in other medical disciplines. The reader will note that in this edition, the use of evidence-based medicine is identified in chapters as appropriate.

Many topics are further supported by algorithms and the enhanced image library available in the ebook version provided along with the print version. Both ICD-9 and preliminary high level ICD-10 codes have been incorporated in preparation for the rollout of ICD-10 in late 2015.

Section II: Short Topics: A to Z consists of more than 1,300 diseases, conditions, presenting complaints, or key concepts in the field that the practitioner must be aware of but may not be worthy of a complete 2-page chapter. Section III has been greatly expanded and now features nearly 90 visual algorithms to enhance many more clinically relevant topics. Section IV is dedicated exclusively to a core discipline in our field: Urinalysis and Urine Studies. Section V: Alternative and Complementary Urologic Therapies is a focused review that is of interest to both patients and caregivers alike. Section VI: Urologic Drug Reference is a very unique collection of information on hundreds of drugs used in urologic practice in the United States as well as some traditionally nonurologic medications that are clinically significant to the urologic practitioner. Additional urologic applications not often found on the package insert for “off-label” use in daily care are included for many medications. These “off-label” applications are noted on the basis of published literature with additional input and the personal observations of the authors and editors. Finally, Section VII: Reference Tables is a collection of useful reference information and forms. A media and image collection is available in this edition.
the ebook version of this book. Please see information inside front cover on how to access this content.

In any project of this magnitude, there are numerous individuals responsible for its success. I would like to thank the following individuals who provided the initial guidance in 1996 to develop the first urology version of the 5-Minute Consult: Lippincott Williams & Wilkins editors Carroll Cann and Craig Percy, and an early pioneer of the 5-Minute Consult concept, Dr. Mark Dambro. Thanks to my administrative assistants Denise Tropea and Barbara Devine, who provided key support to keep the contributors and this edition organized. A special thanks to the more than 370 authors and editors who took the time to contribute to this edition and the numerous contributors to the previous editions that laid a strong foundation for this third update. To my colleagues who served as Associate, Consulting, Specialty and International Editors, my most sincere gratitude and appreciation for the time you took to recruit authors, create and review content. It is also with great sadness that one of our international editors and an icon in the field of Urology, Professor John Fitzpatrick passed away during the completion of this book. He will be missed by all but his numerous contributions to our field will live on.

Residents from the Department of Urology of Thomas Jefferson University and from the University of West Virginia deserve special acknowledgement. They supported the content of both Section II "Short Topics" and Section III "Algorithms." Their names appear in the contributor listing as having been authors but are not specifically recognized for their work in these sections. Now however, they are.

The editorial and production staff at Wolters Kluwer Health have distinguished themselves as the best publishing team I have had the opportunity to work with. My personal interactions with the company and their willingness to discuss any and all issues relating to the book are testimony to their corporate philosophy in respecting the authors’ opinions to develop the best educational products possible in the field of medicine. Brian Brown, Keith Donnellan, and Brendan Huffman are the best partners a medical author could hope to work with. In the final production stages, David Saltzberg and Harish Kumar kept everything moving to stay on schedule. Special thanks to Philadelphia-based friend and professional photographer Robert Neroni, who captured the spirit of urology in our cover photo.

Our children, Leonard, Patrick, Andrew, and Michael, deserve credit for their encouragement and patience over the many years of my time spent working on this project. In this edition, I am very proud that a few of the boys were actually able to make tangible professional contributions.

Most importantly, I would like to thank my wife, Tricia, with the usual and customary accolades that authors share about their spouses in acknowledging the love and support provided. However, her attention to detail as a behind-the-scenes editorial partner and skilled reviewer for final content of this book added a degree of accuracy that I could never have accomplished alone.

Please contact me if you have corrections or suggestions on ways to improve future editions of the book. I hope that The 5-Minute Urology Consult will provide useful information to allow all of us to care for our urology patients in the best way possible.

Leonard G. Gomella, MD

www.urologyquestion.com
Evidence-based medicine (EBM) is generally defined as the use of current best medical evidence to aid in making decisions about the care of an individual patient. While the ultimate decision-making process for or against a given treatment must be made between the patient and the health care provider, EBM seeks to assess the quality of evidence that a specific course of action is based on. The underlying principle is the evaluation of medical interventions and the literature that supports these interventions in a systematic and organized fashion. Since its introduction as a concept in the modern medicine over 30 years ago, there has been increased emphasis on this concept in daily patient care. While there are currently many different systems of EBM, we have adopted the 5-Minute Clinical Consult standard of the “SORT Taxonomy” from the American Academy of Family Physicians. The key components are summarized later. A full review of this article can be viewed at http://www.aafp.org/afp/20040201/548.html. Throughout this edition of The 5-Minute Urology Consult, these evidence-based recommendations can be found. However, we recognize that in a primarily surgical-based specialty such as urology, this area is not yet as well defined as in more general areas of medical practice.

As an illustrative example in a chapter on hypertension, the EBM recommendation might read:

“Use thiazide diuretics as a first-line agent for the treatment of essential hypertension, as it has the greatest efficacy in preventing the vascular complications of hypertension (5A).”

The A designation, as noted in the algorithm later, implies this recommendation is based on the highest-quality, patient-oriented evidence, and should be followed. The number 5 refers to the source, which would be listed under the “References” heading as reference #5. Recommendations that are level A evidence are shaded blue in the text.

Strength of recommendation Definition

A Recommendation based on consistent and good-quality patient-oriented evidence.

- Highest-quality resource, such as a systematic review. This is a summary of the medical literature on a given topic that uses strict, explicit methods to perform a thorough search of the literature and then provides a critical appraisal of the individual studies concluding in a recommendation. The Cochrane reviews are considered by many to be the most prestigious collection of systematic reviews (www.cochrane.org).

B Recommendation based on inconsistent or limited-quality patient-oriented evidence.

- This implies that the data referenced are derived from high-quality randomized controlled trials that were performed to minimize bias in their outcome. Bias is anything that may interfere with the truth; in the medical literature, it is often unintentional but is more common than we appreciate. In short, always assume that some degree of bias exists in any research endeavor.

C Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.

- This implies that the reference used does not meet the “A” or “B” requirements; these are often treatments recommended by consensus groups (such as the American Cancer Society). In some cases, they may be the standard of care. But implicit in a group’s recommendations is the bias of the group or author that supports the reference.

ABDOMINAL MASS, ADULT, UROLOGIC CONSIDERATIONS

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION
Urologic masses are usually retroperitoneal in adults
May arise from several sites
- Renal (malignant and benign)
- Adrenal
- Germ cell (intraperitoneal lymphadenopathy)
- Neoplastic
- Other (intraperitoneal fibrosis [RPF], hematoma, abscess, lymphocele, lymphoma, urinary retention)

EPIDEMIOLOGY
Incidence
- Renal cell carcinoma: 55,000 new cases per year
- Incidence is rising (1)
- Testicular cancer: 8,000 new cases per year
- Renal cell carcinoma: 55,000 new cases per year

Prevalence
Varies with disease type

RISK FACTORS
- Cancer (renal, adrenal, testis)
- Prior surgery (lymphocele)
- Trauma (hematoma, urinoma)
- Infection (abscess, RPF)
- Prior surgery (lymphocele)
- Cancer (renal, adrenal, testis)

PATHOPHYSIOLOGY
- Various urologic pathologic conditions may present with a mass:
  - Primary renal neoplasms:
    - Wilms tumor, renal cell carcinoma, lymphoma
  - Benign:
    - Renal cortical adenoma, renal oncocytoma, renal hamartoma (angiomylipoma) fibroma
  - Primary adrenal neoplasms:
    - Adrenal cortical carcinoma, pheochromocytoma, adrenal adenoma, paraganglioma
  - Hydroptosis
  - Primary and metastatic germ cell tumor (GCT): Are composed of seminoma, embryonal cell carcinoma, yolk sac tumor, teratoma, and choriocarcinoma
  - Primary intraperitoneal GCTs can occur intraperitoneally
  - Metastatic GCTs are associated with retroperitoneal lymphadenopathy

- Renal abscesses: Usually follow insufficient treatment of tubular nephritis; s raw aspiration may be needed to make a diagnosis
- TB can cause calcified abscess formation; Pus developing from a renal source may track alongside psoas muscle and appear in the groin, where it must be distinguished from hernia
- Periphe...
DIFFERENTIAL DIAGNOSIS

- Adrenal mass: See Section I “Adrenal Mass”
- Distended bladder
- Gynecologic:
  - Pregnancy, uterine fibroids, ovarian cysts, malignancy
  - Hydro nephrosis
- Other: Retroperitoneal masses, fluid, and cysts
- Ruptured abdominal aortic aneurysm
- Urachal abnormality

TREATMENT

GENERAL MEASURES

- Varies by underlying ailment
  - Renal malignancy: radical or partial nephrectomy, ablation, observation (3)
  - Adrenal malignancy: adrenalectomy
  - Adrenal adenoma: excision or observation
  - Testis cancer: retroperitoneal lymph node dissection, chemotherapy, radiation
  - Renal abscess, xanthogranulomatous pyelonephritis: antibiotics, drainage, nephrectomy
  - Cysts: excision, decortication, drainage and sclerosis
  - Retention: placement of Foley catheter
  - Hydro nephrosis: double J stent placement or percutaneous nephrostomy tube placement

MEDICATION

First Line
- Antibiotics for abscess or obstruction
  - Corticosteroids, tamoxifen for RPF

Second Line
- Mycophenolate mofetil, azathioprine for RPF

ADDITIONAL TREATMENT

- Radiation Therapy: limited utility for renalcell carcinoma
- Used for seminomatous germ cell tumors

Ongoing Care

PROGNOSIS

Prognosis depends upon clinical diagnosis and staging

COMPLICATIONS

See associated chapters regarding disease-specific interventions

FOLLOW-UP

Patient Monitoring
Depends upon clinical diagnosis and management.

Patient Resources
N/A

CODES

ICD9
- 189.0 Malignant neoplasm of kidney, except pelvis
- 194.0 Malignant neoplasm of adrenal gland
- 789.30 Abdominal or pelvic swelling, mass, or lump, unspecified site

ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C74.90 Malignant neoplasm of unsp part of unspecified adrenal gland
- R19.00 Intra-abd and pelvic swelling, mass and lump, unspecified site

CLINICAL/SURGICAL PEARLS

- Abdominal masses in the adult can arise from several different processes.
- Radiographic information is often essential to diagnosis.
- Management varies upon disease type.
ABDOMINAL MASS, NEWBORN/CHILD, UROLOGIC CONSIDERATIONS

Sang Won Han, MD

Yong Seung Lee, MD

**DIAGNOSIS**

**HISTORY**

- Prenatal ultrasound (1):
  - Glycosuria: Associated with PKD, bilateral UPI, neural tube defects, polyhydramnios, nephrotic syndrome, polyhydramnios, multiple congenital anomalies.
  - Polyhydramnios: Associated with high GI obstruction.
- Postnatal history:
  - Initial diagnosis:
  - Duration from detection of mass:
  - Rapidity of growth:
  - Constitutional symptoms:
  - Fever, pain, weight loss, UFI, diarrhea, hematuria, melena, anorexia, bilious vomiting.

**PHYSICAL EXAM**

- Perform thorough abdominal exam (2):
  - Size and location:
  - Nontender or tender:
  - Solid or cystic:
  - Size and location:
  - Constitutional symptoms:
  - Fever, pain, weight loss, UFI, diarrhea, hematuria, melena, anorexia, bilious vomiting.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- CBC:
  - Leukocytosis suggests possible infection.
  - Anemia, neutropenia, thrombocytopenia may suggest bone marrow involvement.
- Urinalysis:
  - Hematuria seen in Wilms tumor, renal vein thrombosis.
- BUN/creatinine/electrolytes:
  - Elevated BUN/creatinine suggests renal compromise, dehydration.
  - Leukocytosis in boys.

**Imaging**

- Plain abdominal x-rays:
  - Check for obstruction, fluid levels, air-liquid levels, presence of air in rectum.
  - Calcifications suggest nephroblastoma, teratoma, hepatoblastoma, meconium peritonitis, urinary, or biliary stones.
- Ultrasonography & CT:
  - Used to enhance findings on US or solid mass on CT.
  - Used to rule out lower urinary tract pathology.

**DIFFERENTIAL DIAGNOSIS**

- Hydrocystoma: Most common cause of neonatal abdominal mass (70%)
  - UPI obstruction: Most common cause of hydrocystic abdominal mass.
  - Other causes: UVI obstruction, PUV, VUR, megaloureter, and ureteroceles.
  - Unilateral flank mass; more common on left, and boys.
- Nephroblastoma:
  - Wilms tumor: Most common cause of neonatal abdominal masses.
  - Unilateral flank mass; more common on left, and boys.

**RISK FACTORS**

- Variability with disease type.
- Prevalence:
  - Abdominal mass in 1 per 1,000 live births.
- Incidence:
  - Almost 2/3 of infantile abdominal masses arise from kidneys.
  - Most masses are nonsurgical; 87% of surgical masses are renal.

**DESCRIPTION**

- Disease specific.
- Related to organ of origin.

**PATHOPHYSIOLOGY**

- Disease specific.
- Organ of origin.

**GENERAL PREVENTION**

- N/A

**DIAGNOSTIC PROCEDURES/SURGERY**

**PATHOLOGIC FINDINGS**

**DIFFERENTIAL DIAGNOSIS**

- Hydrocystoma: Most common cause of neonatal abdominal mass (70%)
  - UPI obstruction: Most common cause of hydrocystic abdominal mass.
  - Other causes: UVI obstruction, PUV, VUR, megaloureter, and ureteroceles.
  - Unilateral flank mass; male.

**RISK FACTORS**

- Variability with disease type.
- Prevalence:
  - Abdominal mass in 1 per 1,000 live births.
- Incidence:
  - Almost 2/3 of infantile abdominal masses arise from kidneys.
  - Most masses are nonsurgical; 87% of surgical masses are renal.
**Genital mass – RMS:**
- Primary five tumors are 3rd most common solid abdominal mass in childhood (15% total).
- Average lesions: 1/3 Hemangioendothelioma, mesenchymal hamartoma, adenoma, focal nodular hyperplasia, conglomeral cyst.
- Malignant: D1 (Neuroblastoma most common <5 yr; hepatocellular carcinoma present ages 12–15).

**Sphincter mass:**
- Congenital splenic cyst.
- Congenital mesenteric lymphatic malformation.

**Hypertrophic pyloric stenosis**
- 2 major subtypes: Embryonal (most common), 15–20% arise from genitourinary system.
- Presents as large mobile midabdominal mass.
- 1:3,000 girls.
- Pelvic midline mass; US shows fluid-filled mass.
- Due to obstruction from vaginal atresia or Hydrometrocolpos: Gross distension of the vaginal pouch.
- 90% have catecholamine excess.
- Fever, malaise, weight loss; ill-appearing newborn.
- Most common malignancy of newborn.
- Combination surgery, chemotherapy, and radiation therapy are used. Mean age 3.5 mo.
- Most common renal neoplasm of infancy.
- Most common renal tumor diagnosed on antenatal US.
- Fixed, painless, irregular mass that often crosses midline.
- Occasionally rapidly enlarging.
- Differential: Neuroblastoma, Rhabdomyosarcoma (most common in children), benign lesions.

**Surgical approach:**
- Abdominal hysterectomy.
- Adrenal hemangioma.
- Congenital mesoblastic nephroma.

**Radiation therapy**
- Chemotherapy is 1st line prior to radiation or surgery.
- Treatment schema based on INSS stage, age, histopathology.
- MYC amplification, DNA ploidy, and Shimada histopathology.
- RMS: Chemotherapy + surgery is the current treatment of choice.
- Neuroblastoma.
- Polycystic Kidney Disease.
- Multicystic Dysplastic Kidney.
- Wilms Tumor (Nephroblastoma).

**Neuroblastoma**
- Multidisciplinary approach may involve surgery, chemotherapeutic agents, and radiation.
- Chemotherapy is 1st line, followed by surgery and radiation in higher stages.
- Radiation Therapy: Local control is likely by age 1 yr.
- Additional Therapies: Neuroblastoma: Multidisciplinary approach may include bone or stem cell transplantation.

**Lymphoma**
- Common in children.
- Most common malignancy in children.
- 60% non-Hodgkin; 1/3 involve abdomen; can present as intussusception.

**Radiation Therapy**
- Chemotherapy is 1st line prior to radiation or surgery.
- Treatment schema based on INSS stage, age, histopathology.
- MYC amplification, DNA ploidy, and Shimada histopathology.
- RMS: Chemotherapy + surgery is the current treatment of choice.
- Neuroblastoma.
- Polycystic Kidney Disease.
- Multicystic Dysplastic Kidney.
- Wilms Tumor (Nephroblastoma).

**Hemangiomas:**
- Most common congenital vascular anomalies.
- Congenital hemolytic anemias.
- Congenital splenic cysts.
- 12–15% of hepatocellular carcinoma.

**Hepatobiliary masses:**
- Benign lesions: 1/3 (hemangioendothelioma, mesenchymal hamartoma, adenoma, focal nodular hyperplasia, conglomeral cyst).
- Malignant: D1 (Neuroblastoma most common <5 yr; hepatocellular carcinoma present ages 12–15).

**ABDOMINAL MASS, NEWBORN/CHILD, UROLOGIC CONSIDERATIONS**

**Medical Management**
- Stabilize patient as necessary. Treatment is based on diagnosis.

**Surgery/Older Procedures**
- Surgery is specific to disease process. In general, tumors, obstructive/infection problems will need surgery.

**Additional Treatment**
- Radiation Therapy: RMS: Part of a multidisciplinary approach to create therapy including surgical excision and chemotherapy.
- Wilms tumor: For higher stage favorable histology.
- Chemotherapy is 1st line prior to radiation or surgery.
- Treatment schema based on INSS stage, age, histopathology.
- MYC amplification, DNA ploidy, and Shimada histopathology.

**Clinical/Surgical Pearls**
- Determining the age (neonates vs. children) can differentiate between likely etiologies. In general, older children are more at risk for developing malignant masses compared with neonates and young children.
- Two most common entities causing neonatal abdominal mass (U/P): obstruction and MCDF.
- Surgery is usually done in the hydroureteric kidney and nonfunction MCDF.
- Concerning malignant masses, neuroblastoma, and hepatoblastoma are more likely in children <2; older children are more susceptible to Wilms, hepatocellular carcinoma, genitourinary tract tumors, and germ line tumors.

**Follow-up**
- Patient Monitoring: Disease specific.

**Patient Resources**

ACUTE KIDNEY INJURY, ADULT (RENAL FAILURE, ACUTE)
Fernando J. Bianco, Jr., MD
Joan C. Delto, MD

ASSOCIATED CONDITIONS
- Dehydration
- Trauma
- Burns
- Sepsis
- Urinary tract infection
- Chronic renal insufficiency
- Hypertension
- Congestive heart failure
- Liver disease, cirrhosis
- Nephrolithiasis
- BPH
- Advanced prostate or bladder cancer, malignancy
- Malignant hypotension

GENERAL PREVENTION
- Hydration
- Proper renal dosing of medication; daily dosing of antibiotics
- Avoidance of nephrotoxic agents
- Adequate voiding (timed, double voiding)
- Risk of contrast reduced AKI may be reduced by N-acetylcysteine 600 mg PO BID on day prior to and day of contrast and sodium NaCl(Cr): 3 mL/kg/h × 1 hr before and 1 mL/kg/h × 6 hr after contrast administration

DIAGNOSIS
- History
  - Urine: Hematuria, proteinuria, casts, crystals
  - Transient renal hypoperfusion (reversible)
  - Urine output, drain output
  - Volume status, body weight
  - Vital signs: Blood pressure, heart rate, orthostatic changes

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - CBC, BUN, creatinine, electrolytes (including Ca/Mg/Phos), consider arterial blood gases (ABGs)
  - AKI
    - Serum cystatin C (SCr) at least 0.3 mg/dl, over a 48-hr period
    - Over 2.5 times the baseline SCr value within the 7 previous days
  - Common lab abnormalities in AKI:
    - Decrease in Na, phosphate, Mg, uric acid
    - NephroCheckTM detects the presence of insulin-like growth-factor binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases (TIMP-2) in the urine (both AKI associated); the test provides a risk score of developing AKI within 12 hrs
    - Creatinine kinase (rhabdomyolysis)
  - Urine
    - Urinalysis: Blood, protein, casts, crystals
    - Transient renal hypoperfusion (reversible)
    - Hematuria (hemoglobinuria, hemoglobinuria, hemoglobinuria, hemoglobinuria)
    - Proteinuria: Without proteinuria, with proteinuria, with proteinuria, with proteinuria
    - Urinalysis: Blood, protein, casts, crystals
    - Increased: Hematuria, proteinuria, casts, crystals
    - Decreased: Hematuria, proteinuria, casts, crystals
    - Nephrotoxicity: Investigate the presence of insulin-like growth-factor binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases (TIMP-2) in the urine (both AKI associated); the test provides a risk score of developing AKI within 12 hrs
    - Creatinine kinase (rhabdomyolysis)
    - Hematuria (hemoglobinuria, hemoglobinuria, hemoglobinuria, hemoglobinuria)
    - Proteinuria: Without proteinuria, with proteinuria, with proteinuria, with proteinuria
    - Urinalysis: Blood, protein, casts, crystals
    - Increased: Hematuria, proteinuria, casts, crystals
    - Decreased: Hematuria, proteinuria, casts, crystals
    - Nephrotoxicity: Investigate the presence of insulin-like growth-factor binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases (TIMP-2) in the urine (both AKI associated); the test provides a risk score of developing AKI within 12 hrs
    - Creatinine kinase (rhabdomyolysis)
  - Urine
    - Urinalysis: Blood, protein, casts, crystals
    - Hematuria (hemoglobinuria, hemoglobinuria, hemoglobinuria, hemoglobinuria)
    - Proteinuria: Without proteinuria, with proteinuria, with proteinuria, with proteinuria
    - Urinalysis: Blood, protein, casts, crystals
    - Increased: Hematuria, proteinuria, casts, crystals
    - Decreased: Hematuria, proteinuria, casts, crystals
    - Nephrotoxicity: Investigate the presence of insulin-like growth-factor binding protein 7 (IGFBP7) and tissue inhibitor of metalloproteinases (TIMP-2) in the urine (both AKI associated); the test provides a risk score of developing AKI within 12 hrs
    - Creatinine kinase (rhabdomyolysis)

PHYSICAL EXAM
- Vital signs: Blood pressure, heart rate, orthostatic changes
- Volume status, body weight
- Urinary output, drain output

PHYSICAL EXAM
- Vital signs: Blood pressure, heart rate, orthostatic changes
- Volume status, body weight
- Urinary output, drain output
Diagnostic Procedures/Surgery

- Cystoscopy with retrograde pyelography
- Renal biopsy (acute glomerular nephritis)

Pathologic Findings

- Acute glomerular nephritis
  - Interstitial edema, marked interstitial infiltrate of T cells and monocytes
  - Eosinophils, plasma cells
  - PMN cells
  - Granulomas

DIFFERENTIAL DIAGNOSIS (4)

- Prerenal (≈55%): Hypovolemia, volume depletion (iv fluids, excessive sweating, dehydration, hemorrhage), renal artery stenosis/embolism, burns, heart failure, liver failure
- Intravascular (≈40%): ATN (from prolonged prerenal insufficiency, radiographic contrast material, aminoglycosides, NSAIDs, or other nephrotic substances); glomerulonephritis, acute interstitial nephritis (drug-induced); arteriolar insult; nephritis (drug-induced); arteriolar insults; vasculitis; glomerular substances; glomerulonephritis; acute interstitial nephritis
- Postrenal (≈5%): Extravascular compression (eg, BPH, carcinoma, pregnancy), intrinsic obstruction (eg, calculus, tumor, clot, stricture, sloughed papilla); decreased function (eg, neoplastic bladder)
- Paused AHT: Exogenous chromogens (eg, bilirubin, ascorbic acid, uric acid) and exogenous chromogens (eg, cephalosporins, trimethoprim, cimetidine) may interfere with the creatinine assay and cause falsely elevated results.

TREATMENT

GENERAL MEASURES

- All require close management of fluid, acid-base, and electrolyte balance and the removal of urinary toxins
- Captopril, a dopamine agonist, may decrease AKI
- Furosemide is ineffective in preventing and treating AKI
- Prerenal
  - Renal perfusion; isotonic fluid replacement
- Postrenal
  - Foley or suprapubic tube drainage
- Ensure proper placement within bladder
  - urine present within bladder
  - Rule out catheter obstruction (musca, clot)
- Peritoneal nephrostomy tube
- Treatment of hyperkalemia
  - Monitor EKG when K+ > 6 mEq/L
  - iv calcium
  - Sodium bicarbonate (pH adjust)
  - Insulin and glucose
  - Kayexalate
  - Hemodialysis for severe hyperkalemia or refractory to treatment
- Control of urinary extravasation
- Dietary considerations
  - Maintain carbohydrate and protein intake
  - Restrict: Phosphorus, potassium, sodium
  - Monitor of creatinine, potassium, calcium, and phosphorus
  - Repeat imaging (US) to re-evaluate hydronephrosis
  - If question of stent migration, obtain KUB or US
  - Urinary stents will need to eventually be exchanged or removed
- Consideration of internalization of percutaneous nephrostomy tubes

Patient Resources

- See Also (Topic, Algorithm, Media)
  - Acute Kidney Injury (AKI), Pediatric (Renal Failure, Acute)
  - Acute Glomerulonephritis
  - Acute Tubular Necrosis
  - Contrast-Induced Nephropathy (CIN)
  - Postobstructive Diuresis

ICD9

- 584.3 Acute kidney failure with lesion of tubular nephrons
- 584.9 Acute kidney failure, unspecified
- 593.81 Vascular disorders of kidney

ICD10

- N17.0 Acute kidney failure with tubular necrosis
- N17.9 Acute kidney failure, unspecified
- N28.0 Ischemia and infarction of kidney

CLINICAL/SURGICAL PEARLS

- Maximize urinary drainage.
- Avoid nephrotoxic agents.
- Upper tract obstructive uropathy should be acutely managed by stent vs. percutaneous nephrostomy.
ACUTE KIDNEY INJURY, PEDIATRIC (RENAL FAILURE, ACUTE)
Leigh Mark Etinger, MD, MS
Kenneth Lieberman, MD

PATHOPHYSIOLOGY
- Prerenal and intrinsic renal injury disrupt the regional perfusion of, and subsequent oxygen delivery to, the kidney(s).
- The renal arterial gradient of oxygen tension from comes to medulla makes the kidney highly susceptible to hypoxic and oxidative injury during ischemia and reperfusion.
- Prion-like perforated glomerular endothelial cells release vasoactive substances, proteases, reactive oxygen species, and nitric oxide and activate the coagulation cascade and complement pathways.
- Even well-perfused kidneys can develop AKI during sepsis from circulating cytokines, lymphocytes, T cells, and other factors.
- When faced with the presence of cardiac, pulmonary, or hepatic failure it is likely due to endothelial activation or circulatory abnormalities.
- Nephrotoxic agents such as their own mechanism of damage, eg, by forming crystals in the microcirculations of the kidney.
- Rhabdomyolysis causes intravascular vasodilatation, direct ischemic tubular injury, and tubular obstruction in acidic urine.
- Prerenal injury is due to intraglomerular flow disruption from the kidney.
- Must be bilateral to cause PRFLE findings but can be unilateral if only one kidney is present due to congenital absence, prior nephrectomy, or kidney transplant.
- AKI is multifactorial, especially in the ICU setting.

ASSOCIATED CONDITIONS
CKD increases the risk for AKI.

GENERAL PREVENTION
- Prerenal:
  - Maintain cardiac output and oxygenation with vasopressors and blood transfusions as needed.
  - Intrinsic renin:
  - Careful dosing and therapeutic drug level monitoring of antihypertensives or avoidance altogether.
  - Use lipid formulation of angiotensin II or another antifibrinolytic alternative.
  - Contrast-induced AKI
  - Avoid the use of contrast.
  - Use either iso- or low-osmolar iodinated contrast media.
  - Intravenous fluid expansion for those patients at risk.
  - Acute NSAIDs
  - Animal models have shown the potential benefit of vasodilators, growth factors, antioxidants, and anti-inflammatory drugs in preventing AKI.
  - A single dose of theophylline given to neonates with severe perinatal asphyxia has been shown to significantly reduce the risk of AKI.

DIAGNOSIS

HISTORY
- Evaluate for shock, sepsis, bleeding, dehydration, gastrointestinal losses.
- Assess recent medication exposure, including natural products.
- History of urologic surgery, anatomic problems, or kidney transplantation.
- Family history of ESRD, HUS.
- Recent trauma, crush injury.
- Seek signs of CKD, such as growth delay.
- Review recent blood tests to determine baseline serum creatinine (SCr) and onset of AKI.

PHYSICAL EXAM
- Assess hydration status, blood pressure, heart rate, and temperature.
- Lungs for rales.
- Abdomen for masses.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- SCr and blood urea nitrogen will be elevated.
- May have hyperkalemia, acidosis.
- Hemoglobin will be low if bleeding.
- HUS causes thrombocytopenia, increased lactate dehydrogenase.
- Muscle damage is the cause creatinine kinase will be elevated and urinary myoglobin will be positive.
- Unlikely to detect red blood cells, proteinuria.
- Urine eosinophils indicate interstitial nephritis.
- Store UOP monitoring to assess AKI stage and progression.

Imaging
- Renal ultrasound with Doppler analysis of the renal artery and veins.
- Hypoechoic indicates obstruction.
- Increase echogenicity consistent with medical renal disease.
- Thrombosis of renal artery or vein.
- Small echogenic kidneys, cystic kidneys indicate CKD.

- Bladder ultrasound
- Thrombosed, thick-walled bladder may indicate lower urinary tract abnormality such as a neurogenic bladder or obstruction.

- Technetium-99m MAG3 renal scan can be used in prolonged AKI to differentiate prolonged ATN from permanent cortical necrosis.

BASICS

DESCRIPTION
- A system or recently acquired functional impairment of the kidney relative to physiologic demands with or without actual kidney injury.
- Causes: Red to potentially life-threatening alterations in fluid, electrolyte, acid-base and hormonal homeostasis.
- Terminology: acute tubular necrosis (ATN) to acute renal failure (ARF) to acute kidney injury (AKI) of varying grades to standardize reporting, clinical care, and research.
- Diagnosis: the Pediatric Modified Risk Injury (pRIFLE) criteria on the estimated creatinine clearance (eCrCl), based on Schwartz formula) and urine output (UOP) (I):
  - Risk: eCrCl decrease by 25% and/or UOP <0.5 mL/kg/h for 8 hr.
  - Injury: eCrCl decrease by 50% and/or UOP <0.5 mL/kg/h for 16 hr.
  - Failure: eCrCl decrease by 75% or eCrCl <35 mL/min/1.73 m2 and/or UOP <0.3 mL/kg/h for 24 hr or anuria for 12 hr.
  - Loss: Persistent failure in AKI.
- Postrenal injury is due to antegrade urine flow disruption from the kidney.
  - Must be bilateral to cause pRIFLE findings but can be unilateral if only one kidney is present due to congenital absence, prior nephrectomy, or kidney transplant.
  - AKI is multifactorial, especially in the ICU setting.

ASSOCIATED CONDITIONS
CKD increases the risk for AKI.

GENERAL PREVENTION
- Prerenal:
  - Maintain cardiac output and oxygenation with vasopressors and blood transfusions as needed.
  - Intrinsic renin:
  - Careful dosing and therapeutic drug level monitoring of antihypertensives or avoidance altogether.
  - Use lipid formulation of angiotensin II or another antifibrinolytic alternative.
  - Contrast-induced AKI
  - Avoid the use of contrast.
  - Use either iso- or low-osmolar iodinated contrast media.
  - Intravenous fluid expansion for those patients at risk.
  - Acute NSAIDs
  - Animal models have shown the potential benefit of vasodilators, growth factors, antioxidants, and anti-inflammatory drugs in preventing AKI.
  - A single dose of theophylline given to neonates with severe perinatal asphyxia has been shown to significantly reduce the risk of AKI.

DIAGNOSIS

HISTORY
- Evaluate for shock, sepsis, bleeding, dehydration, gastrointestinal losses.
- Assess recent medication exposure, including natural products.
- History of urologic surgery, anatomic problems, or kidney transplantation.
- Family history of ESRD, HUS.
- Recent trauma, crush injury.
- Seek signs of CKD, such as growth delay.
- Review recent blood tests to determine baseline serum creatinine (SCr) and onset of AKI.

PHYSICAL EXAM
- Assess hydration status, blood pressure, heart rate, and temperature.
- Lungs for rales.
- Abdomen for masses.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- SCr and blood urea nitrogen will be elevated.
- May have hyperkalemia, acidosis.
- Hemoglobin will be low if bleeding.
- HUS causes thrombocytopenia, increased lactate dehydrogenase.
- Muscle damage is the cause creatinine kinase will be elevated and urinary myoglobin will be positive.
- Unlikely to detect red blood cells, proteinuria.
- Urine eosinophils indicate interstitial nephritis.
- Store UOP monitoring to assess AKI stage and progression.

Imaging
- Renal ultrasound with Doppler analysis of the renal artery and veins.
- Hypoechoic indicates obstruction.
- Increase echogenicity consistent with medical renal disease.
- Thrombosis of renal artery or vein.
- Small echogenic kidneys, cystic kidneys indicate CKD.

- Bladder ultrasound
- Thrombosed, thick-walled bladder may indicate lower urinary tract abnormality such as a neurogenic bladder or obstruction.

- Technetium-99m MAG3 renal scan can be used in prolonged AKI to differentiate prolonged ATN from permanent cortical necrosis.
Differential Diagnosis
Kidney biopsy may reveal ATN, interstitial disease, or glomerulonephritis.

Pathologic Findings
Prolonged AKI without a clear etiology may require prolonged dialysis or need for surgical intervention.

Diagnostic Procedures/Surgery
- Hemodialysis or peritoneal dialysis may play a role in supportive care.
- Continuous renal replacement therapy (CRRT) has been shown to improve pediatric AKI.

Surgical Intervention
- Bilateral nephrolithiasis due to cystinuria may be managed with extracorporeal shock wave lithotripsy, endoscopic surgery, or surgery.

Medication
- Avoid potentially nephrotoxic drugs and gadolinium.
- Nephrogenic systemic fibrosis (NSF) is a rare but potentially lethal fibrosing disorder of the skin, liver, and heart.

Prognosis
- Mortality may be increased in pediatric AKI.
- The Pediatric Modified Risk Injury Failure Loss End Stage (Pediatric M-RIFLE) is used to assess outcomes.

Additional Reading
See also (Topic, Algorithm, Media): Acute Kidney Injury, Adult; Acute Kidney Injury, Pediatric; Chronic Kidney Disease, Pediatric; Radiation Therapy.

Clinical/Surgical Pearls
- AKI is multifactorial.
- Seek prompt medical attention when AKI is present.
- Avoid potential nephrotoxic drugs and gadolinium.

Follow-Up
- Patient Monitoring: Monitor I&O, blood pressure, somatic growth, urinalysis for signs of CKD after resolution of AKI.
- Patient Resources:
  - American Society of Pediatric Nephrology: www.aspneph.com/parentpatient.asp
  - Kidney & Urology Foundation of America: www.kidney.org/patients/index.cfn

ACUTE SCROTUM

Patrick T. Gomella, MD, MPH
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION
- Acute pain and swelling in the scrotum is typically related to testicular pathology and is usually referred to as “acute scrotum”. In the absence of obvious trauma.
- Occasionally pain from urinary colic can be referred to the testicle but swelling is usually absent.
- Chronic testicular pain is referred to orchalgia.
- Testicular torsion is a major cause of the acute scrotum particularly in children and requires timely diagnosis and treatment to avoid testicular loss.
- In adults acute epididymitis-orchitis is the most common cause of an acute scrotum.
- In children torsion of a testicular appendix or testicle are most common causes.

EPIDEMIOLOGY

Incidence
- Testicular torsion occurs most commonly in neonates and postpubertal boys and is more common on the left.
- However in 1 series 39% of patients were reported to be in men >21 yr of age (1).
- Torsion of an appendix more common in prepubertal boys.
- Approximately 600,000 cases of epididymitis/in US.

Prevalence
- Testicular torsion: 1:4,000 males.
- Testicular torsion reported in 10% of family members;

Genetics
- Testicular torsion reported in 10% of family members; may be autosomal or X-linked recessive; no specific genetic defects identified.

PATHOPHYSIOLOGY

- Testicular torsion can be either intravaginal or extravaginal.
- Intravaginal testicular torsion is twisting of the spermatic cord within the tunica vaginalis.
- Usually due to a so-called “bell clapper deformity.” A failure of normal posterior anchoring of the gubernaculum, epididymis, and testis.
- Leaves the testis free to rotate within the tunica vaginalis of the scrotum much like the clapper inside of a bell (present in 12% of males).
- Intravaginal testicular torsion is twisting of both the spermatic cord and tunica vaginalis.
- Perinatal: Extravaginal testicular torsion is usually the cause.

• Appendiceal torsion is a result of vascualr compromise may be related to pedunculated anatomy of the appendix.
• Appendicular testis 95% of appendiceal torsions.
• Appendix appendicus torsion is less common.
• Epididymitis
• Can present as acute or chronic epididymitis.
• Acute: Severe swelling, tenderness, rigors, high fevers
• Infectious causes
• In men >25 yr of age, Chlamydia trachomatis and Neisseria gonorrhoeae (sexually transmitted infections) are the most common pathogens.
• In men >35 yr of age colibactin most common
• Less common pathogens: Ureaplasma, TB, Brucella species; with HIV infection, Cytophaga/lymphogranulomatis, and Cryptococcus.
• Less frequent causes include autoimmune diseases, sarcoid, trauma.
• In a prepubertal boy epididymitis is almost always associated with a urinary tract anomaly.

ASSOCIATED CONDITIONS
- Torsion:
  - Bell clapper deformity: 10–15% of males
  - Cryptorchidism
  - Other sexually transmitted infections
  - Prostatic hypertrophy

GENERAL PREVENTION
- Torsion: Reduce testicular loss risk by:
  - Early diagnosis and treatment
  - Community awareness about testes pain
  - Elective bilateral orchidopexy for intermittent pain
  - Community awareness about testis pain

DIAGNOSIS

HISTORY
- Rule out any traumatic insult to the genit area:
  - Some patients report minor trauma before presentation of torsion.
- Sexual practice history
  - Recent urinary tract instrumentation
- Testicular torsion:
  - The classic presentation is sudden hemiscrotal pain often awakening the patient from sleep
  - Pain can radiate to the groin
  - Nausea and/or vomiting can be present
  - Movement tends to worsen the pain
  - A history of intermittent testicular discomfort may be present suggesting past torsion and detorsion
- Appendiceal torsion:
  - Symptoms are similar to testicular torsion but not as severe.
  - Epididymitis
  - Can present with acute fever, chills, rigors, or as chronic testicular/appendix discomfort
  - More likely to be associated with voiding complaints than torsion.

PHYSICAL EXAM

- General:
  - Vital signs; low-grade fevers with torsion, fever with UTI
  - Presence of inguinal hernia
  - Abdominal and flank tenderness
- GI exam:
  - Ausis crematric reflex (2).
  - Assess crematric reflex:
  - Normal is contraction of the cremaster muscle with elevation of the testis.
  - Absent reflex may aid in differentiating testicular torsion from epididymitis/other causes of an acute scrotum where reflex is present.
  - Phren sign (pain relief with elevation of testicle)

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- “W subsidi:
  - White cells and positive leukocyte esterase
  - Signs of epididymitis or UTI
  - Red blood cells suggest renal or urethral source of pain (eg, stone)
  - In cases of torsion UA usually negative

URINE CULTURE:
- Possible if epididymitis or UTI suspected.
- Consider leukocyte esterase if leukocyte esterase is present.
- Culture and nuclear acid amplification testing for chlamydia and gonorrhea.

IMAGING
- Scrotal US with Doppler:
  - Intravaginal testicular torsion findings
  - Usually shows decreased or absent arterial flow but may be normal.
- Appendecial torsion findings:
  - Normal exam most common
  - Spermatic cord complex mass without vascular flow may be present.
- Epididymitis:
  - Enlarged epididymis reported as “epididymitis” often present
  - Doppler flow normal or increased.
ACUTE SCROTUM

Diagnostic Procedures/Surgery
In cases of testicular torsion, surgical exploration is usually diagnostic and therapeutic.

Pathologic Findings
N/A

Differential Diagnosis
- Abscess or other infection such as Furuncle gangrene
- Appendiceal torsion (appendiceal tests or epididymis: testo)
  - Most commonly seen in prepubertal boys
  - Most common cause of acute scrotum in this age group
- Epididymitis due to UTI or STD: Rare or uncommon
  - In pediatric age group, more likely in adult
  - Often associated with genitourinary trauma
- Henoch–Schönlein purpura
  - Rash usually present
  - Incorparated inguinal hernia
- Orchitis: With the exception of mumps orchitis, isolated orchitis without epididymitis in adults is rare
  - Referred pain: Urolithiasis or intra-abdominal process such as appendicitis
- Testicular infarction due to spermatic cord injury or thrombosis
  - Testicular torsion: Most common in peripubertal boys but can occur at any age, less common than appendiceal torsion
  - Testicular tumor: Usually painless but may have tenderness with trauma
  - Trauma and possible testicular rupture: History suggestive, hemorrhage usually present
  - Orchidectomy: Consider avoiding feminization

TREATMENT

ALERT
Testicular torsion is a surgical emergency because the likelihood of testicular salvage diminishes with the duration of torsion.

General Measures
- Clinical history, exam, and diagnostic studies (ultrasound, Color Doppler Ultrasonography) have a high degree of accuracy in making the diagnosis
- Emergency exploration indicated if evaluation suggests irreversible testicular torsion or diagnosis is equivocal
  - If torsion is present and surgery cannot be performed in a reasonable amount of time, manual detorsion should be considered
  - Most cases of epididymitis can be treated on an outpatient basis

Medication
First Line
Epididymitis: Acute
- Iox, scrotal elevation, and NSAIDs with antipyretics
- Younger males: Ceftriaxone (250 mg IM) along with doxycycline (100 mg PO BID x 10 days)
- Older males: Ceftriaxone (250 mg IM) along with a 10-day course of fluoroquinolones for enteric organisms (ciprofloxacin 500 mg PO BID or levofloxacin 500 mg PO BID)
- Epididymitis: Chronic
  - Scrotal elevation, avoid sexual and athletic activity, warm baths, and NSAIDs
  - Appendiceal torsion: bioptern to reduce inflammation and discomfort
  - Testis torsion: Pain control may require opioids

Second Line
N/A

Surgery/Other Procedures
- Urgent exploratory/ultrasound exploration for extravasational testicular torsion to avoid asymmetrical contralateral torsion
- Manual detorsion: Use only if surgery is delayed >2 hr
  - Testis most often rotates medially during torsion
  - Manual detorsion is accomplished by attempting to rotate the testicle laterally toward the thigh
  - The twisting can range from 180–720 degrees such that multiple detorsion twists may be required
  - However, if the testis is >1/3 of the testis, the torsion rotation can be lateral
  - Successful detorsion still requires operative intervention and orchidectomy

Hallmarks of successful manual detorsion include
- Pain relief, testicle assuming a lower position in the scrotum, reorientation of the testicle from transverse lie to vertical positioning, restoration of Doppler blood flow

Additional Treatment
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

Follow-Up

Patient Monitoring
Epididymitis due to culture proven C. orchitidis or N. gonorrhoeae: refer sex partners for evaluation and treatment disease

Patient Resources

See Also (Topic, Algorithm, Media)
- Acute Scrotum Algorithm
- Adult Scrotum Image
- Appendix: Tests and Appendiceal Epidiymis, Torsion
- Epididymitis
- Testis, Torsion, or Testicular/Epididymal Appendages

ICD
N/A

ICD9
- 609.90 Ochitis and epididymitis, unspecified
- N08.9 Unspecified disorder of male genital organs
- N08.2 Torsion of testes, unspecified

ICD10
- N44.00 Torsion of tests, unspecified
- N44.10 Testicular torsion and separation
- N50.9 Disorder of male genital organs, unspecified

Clinical/Surgical Pearls
- Color Doppler ultrasonography is the preferred imaging technique for evaluating the acute scrotum.
  - Cremasteric reflex is usually absent in testicular torsion.
ACUTE TUBULAR NECROSIS
Costas D. Lallas, MD, FACS

ASSOCIATED CONDITIONS
- Sepsis
- Hemorrhage (operative, obstetric, trauma)
- Pre-existing renal insufficiency (diabetes, hypertension)
- Edematous states such as CHF

GENERAL PREVENTION
- Avoid prolonged renal ischemia by timely management of hemorrhage, dehydration and other causes of renal hypoperfusion
- Avoidance of contract agents in the setting of renal insufficiency (contrast-induced nephropathy)
- Appropriate management of potentially nephrotoxic medications

DIAGNOSIS
HISTORY
- Specific attention to:
  - Hypertensive episode, blood transfusions, intravenous contrast exposure
- Meticulous listing of medications to include dosage
- Lab tests:
  - Rate of rise of plasma creatinine: Rise of <0.3–0.5 mg/dL in ATN vs. slower rise with ischemic or toxic insults
  - BUN/plasma creatinine ratio: The ratio is normal at 10 to 15:1 in ATN, but >20:1 in prerenal disease due to the increase in passive reabsorption of urea, the ratio may also be increased with GI bleed, muscle breakdown, and administration of corticosteroids or tamsulosine
  - Rate of rise of plasma creatinine: Rise of >0.3–0.5 mg/dL in ATN vs. slower rise with prenal disease
  - Urine tests:
    - Ureteral: Muddy brown granular and epithelial cell casts and free epithelial cells secondary to sloughing of the tubular epithelium vs. amorphous in prerenal disease
    - Urine sodium concentration: High (>40 mEq/L) due to tubular injury vs. <20 mEq/L in prerenal disease
    - Fractional excretion of sodium (FENa): Above 2% in ATN while <1% in prerenal disease, measured as urine Na divided by plasma Na times plasma Cr divided by urine Cr, although causes of ATN associated with a low FENa that are due to intravascular contrast material, rhabdomyolysis, sepsis, and multisystem organ failure
    - Urine osmolality: Urine osmolality <450 mOsm/kg in ATN secondary to loss of concentrating ability
    - 500 mOsm/kg in prerenal disease
    - Urine creatinine concentration divided by plasma creatinine concentration: Ratio <20:1 in ATN while >40:1 in prerenal disease, reflecting loss of tubular water reabsorption

IMAGING
- Renal ultrasonography:
  - Sensitivity test to determine obstruction, Doppler can detect gross blood flow in renal vein and artery
  - Plain abdominal film
    - Identifies the presence or location of renal calculi and is particularly helpful to discern the proper position of stents and drains
- Functional studies
  - Nuclear scans can determine perfusion or tubular secretion; MRI can give some functional information while providing anatomic information

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Tubal cell injury (TUB): Tubal epithelial cells are particularly sensitive to ischemia and are also submitted to toxicants. The structural changes include those of reversible injury (such as cellular swelling, loss of brush border and polarity, bleeding, and cell detachment) and those associated with lethal injury (necrosis and apoptosis)
- Disturbances in blood flow:
  - Intrarenal reperfusion results in both reduced glomerular blood flow and reduced oxygen delivery to the functionally important tubules in the outer medulla (thick ascending limb and straight segment of the proximal tubule)

DIFFERENTIAL DIAGNOSIS
- Prerenal azotemia
- Postrenal azotemia
- Other forms of renal azotemia
- Glomerulonephritis, disseminated intravascular coagulopathy, arterial or venous obstruction, intravascular precipitation

PATHOPHYSIOLOGY (1)
- Acute tubular injury
  - Renal hypoperfusion and renal ischemia are the most common causes of ATN
  - The ischemic form is due to the reductions in glomerular filtration rate (GFR) secondary to vascular and tubular factors
  - Ischemia from reductions in GFR from decreased renal plasma flow or distal to the afferent arteriole. After return of normal blood flow, ATN persists secondary to tubular changes
  - In addition, both exogenous and endogenous nephrotoxic compounds exist
- Tubular factors: Backleak and tubular obstruction

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum tests (2):
  - BUN/plasma creatinine ratio: The ratio is normal at 10 to 15:1 in ATN, but >20:1 in prerenal disease due to the increase in passive reabsorption of urea, the ratio may also be increased with GI bleed, muscle breakdown, and administration of corticosteroids or tamsulosine
  - Rate of rise of plasma creatinine: Rise of >0.3–0.5 mg/dL in ATN vs. slower rise with prenal disease

RISK FACTORS
- Decreased renal perfusion from:
  - Prolonged hypotension, surgical interruption of blood supply to kidneys
  - Contraindications to nephrotoxic agents:
    - Nonsteroidal anti-inflammatory drugs (NSAIDs), and ACE inhibitors, cyclosporine
  - Nephrotoxic agents:
    - Radiocontrast media (low osmolality is possibly safer), amphotericin, amphotericin, tubular obstruction secondary to a sloughed brush border, cellular debris, Tamm-Horsfall protein, and decreased filtration pressure contribute to obstruction and maintenance of ATN
**TREATMENT**

**GENERAL MEASURES**
- Define and treat the underlying cause.
- Discontinue any nephrotoxic agents.
- Prophylaxis and treatment of complications of ARF.
- Early nephrology consultation.
- Management of fluid disturbances.
- Maintain a euvolemic state by restricting total fluids to no more than urine output plus insensible losses.

**MEDICATION**

**First Line**
- High-dose loop diuretics (1–3 g/d) may convert oliguric to nonoliguric ATN in some patients; it has not been determined that this conversion decreases the duration of ATN or mortality. Oliguria may increase urine output, but its benefit is in question.
- Studies suggest that patients who respond to mannitol, furosemide, or dopamine with an increased urine output have better outcomes than nonresponders.
- Management of electrolyte disturbances.
- Electrolyte disturbances can be minimized by prophylactic institution of a low-potassium, low-protein diet accompanied by fluid restriction and oral phosphate binders.
- Hyperkalemia is the most common and most dangerous abnormality and should be treated aggressively with calcium supplementation until potassium levels can be reduced with combinations of insulin and glucose or potassium-binding resins.

**Second Line**

**SURGERY/OTHER PROCEDURES**
- Metabolized urea, pentobarbital (PB), and continuous arteriovenous hemofiltration (CAVH) — CAVH: Need ICU, limited mobility, need anticoagulation, removes fluid but slow correction of electrolyte abnormalities
- PB: To artificial renal failure but slower correction of electrolyte abnormalities
- HD: Expensive, anticoagulation necessary, vascular access necessary but allow rapid correction of fluid and electrolyte abnormalities

**ADDITIONAL TREATMENT**

**Radiation Therapy**

N/A

**Additional Therapies**

N/A

**Complementary & Alternative Therapies**

N/A

**ONGOING CARE**

**PROGNOSIS**
- Slight improvements in survival in those patients with ATN requiring dialysis, in an ICU setting.
- The Mayo Clinic compared 1977–1979 with 1991–1992 showed high survival both in hospital (32% vs. 32%) and at 1 yr (30% vs. 21%)
- Higher mortality rates are seen in elderly patients and in patients with respiratory failure, multiple organ failure, pre-existing chronic diseases, and systemic hypertension
- Major causes of death are infection and underlying disease, not renal failure
- Patients at risk are generally very ill, with evidence of multiple organ dysfunction
- Of patients who survive ATN, nearly half will have a complete recovery of renal function and a majority of the remainder have an incomplete recovery. Only about 5% of all ARF patients require chronic maintenance dialysis

**COMPLICATIONS**
- Fluid overload, electrolyte disturbances, metabolic acidosis
- Hyperkalemia, edema, acute pulmonary edema, hypernatremia, hyperpercapnia, hyperglycemia, hyperuricemia, hyperkalemia
- Furosemide, dopamine
- GI: Nausea, vomiting, GI bleed; neurologic: Encephalopathy, coma, seizures, peripheral neuropathy; cardiac: Pericarditis, uremic pneumonitis; hematologic: Bleeding, anemia; immunologic: Impaired granulocyte/polyclonal function

**FOLLOW-UP**

**Patient Monitoring**
- Duration
  - Renal failure phase usually lasts 7–21 days if the primary insult (ischemia, nephrotoxin) can be corrected. Recovery is usually heralded by a progressive increase in urine output and a return of BUN and Cr to the previous baseline.
  - Recovery of renal function
  - Irreversible loss of renal function can occur if the combination of pre-existing renal disease and prolonged ARF secondary to repeat ischemic insults and/or nephrotoxic administration
  - If the patient survives, baseline Cr is usually only 1–2 mg/dL above baseline.
- Those patients that need dialysis and have bioincompatibility with the dialysis membrane or have repeat episodes of hyperkalemia have a worse prognosis.

**CLINICAL/SURGICAL PEARLS**

- High-dose loop diuretics (1–3 g/d) may convert oliguric to nonoliguric ATN in some patients; it has not been determined that this conversion decreases the duration of ATN or mortality.
- Of patients who survive ATN, nearly half will have a complete recovery of renal function and a majority of the remainder have an incomplete recovery. Only about 5% of all ARF patients require chronic maintenance dialysis.
- A patient’s weight is helpful information, and its daily measurement is important in the diagnosis and management of ARF.
ADDISON DISEASE
Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

**BASICS**

**DESCRIPTION**
- Primary adrenocortical insufficiency
- Inadequate production of glucocorticoid and mineralocorticoid
- Differentiated from secondary (pituitary) and tertiary (hypothalamic) causes of adrenal causes of adrenocortical insufficiency in which mineralocorticoids are normally spared

**RISK FACTORS**

**Prevalence**
- 93–140 per million (1)
- Females more frequently affected than males
- 4.7–6.2 per million in Western populations (1)

**Incidence**
- 50–140 per million (1)
- Mortality: 0.3 per 100,000

**GENERAL PREVENTION**
- No general prevention guidelines exist for prevention of primary hypoaldosteronism.

**PATHOPHYSIOLOGY**

**Autocrine disorders** are the most common cause in developed nations (90–90%)
- 90% of adrenal gland must be destroyed to cause insufficiency
- Decreased production of cortisol, aldosterone, and adrenal androgens
- Hyperpigmentation due to increased ACTH and proopiomelanocortin-related peptides
- Hypocalcemia due to increased PTHrP

**ACUTE ADRENAL INSUFFICIENCY**

- Classic triad: Hyponatremia, hyperkalemia, azotemia
- Acute adrenal insufficiency: Life-threatening hypotensive shock

**DIAGNOSTIC TESTS & INTERPRETATION**

**Screening test**
- Low cortisol (<165 nmol/L)
- Elevated ACTH (>45 pmol/L)

**Confirmation of abnormal screening test**
- Serum cortisol at 0, 30, and 60 min
- Peak cortisol >550 nmol/L diagnostic (2)

**ASSOCIATED CONDITIONS**
- Autoimmune endocrine disorders
- Thyroid disorder (17%)
- Diabetes mellitus (12%)
- Gonadal dysfunction (12%)

**GENERAL PREVENTION**
- No general prevention guidelines exist for prevention of primary hypoaldosteronism.
Diagnostic Procedures/Surgery
No specific diagnostic procedures
Pathologic Findings
Atrophic adrenals in autoimmune adrenalitis

DIFFERENTIAL DIAGNOSIS
Primary adrenal insufficiency (Addison disease)
Secondary adrenal insufficiency (pituitary failure)
No hyperpigmentation (lack of ACTH elevation)
Etiologies include chronic steroids, pancytopenia, infarction, struma ovarii, pituitary apoplexy, pituitary surgery
Tertiary adrenocortical insufficiency

TREATMENT
GENERAL MEASURES
Acute adrenal insufficiency (addisonian crisis)
5 S’s:
Salt
Sugar
Steroids
Support
Search for precipitating cause

MEDICATION
First Line
Cortisol replacement:
– Hydrocortisone 10–25 mg tid
– BID dosing: 20 mg, 10 mg
– TID dosing: 15 mg, 5 mg, 5 mg
– Monitor body weight and signs/symptoms of over/under replacement
Mineralocorticoid replacement:
– Fludrocortisone 0.05–0.20 mg/d
– Monitor blood pressure, peripheral edema, serum sodium, and potassium
Major stress: Surgery, Trauma, sepsis
– IV hydrocortisone 100–300 mg/TID dosing
then taper
– Monitor stress
– Increase steroid dose 2–3 fold then taper over several days
Second Line
Dehydroepiandrosterone (DHEA) replacement
– 25–50 mg/d
– Impacts mood/feeling of well-being (3)

SURGERY/OTHER PROCEDURES
Stress dose steroids: 25–150 mg hydrocortisone or 5–30 mg methylprednisolone IV day of the procedure in addition to maintenance therapy; taper to the usual dose over 1–2 days

ADDITIONAL TREATMENT
Radiation Therapy

Additional Therapies
Salt loading prior to major stress recommended by some
Future advances using long-acting hydrocortisone preparations to better mimic physiologic case

Complementary & Alternative Therapies
No established alternative therapies

ONGOING CARE
PROGNOSIS
Adrenal crisis may be lethal.
Recommended dosages for glucocorticoid and mineralocorticoid replacement rarely cause significant side effects; dose monitoring is essential to prevent excess treatment.

COMPLICATIONS
Side effects of excess steroid replacement:
– Weight gain, high BP, hyperglycemia, growth retardation, bruising, cardiovascular risks, gastric ulcers, poor wound healing, skin striae, osteoporosis
Side effects of excess mineralocorticoid:
– Hypertension, bradycardia, hyperkalemia, congestive heart failure, suppressed renin levels, growth retardation
– Acute withdrawal of chronic steroid replacement may precipitate acute adrenal crisis
Must rule out or treat glucocorticoid deficiency prior to initiation of thyroxine for hypothyroidism, as this may precipitate adrenal crisis

FOLLOW-UP
Patient Monitoring
– Medic-alert bracelet to be worn at all times
– Instruct patients on proper use of emergency hydrocortisone injections
– Monitor for signs of appropriate glucocorticoid and mineralocorticoid replacement

Patient Resources
– www.addisonsdisease.net
– www.addisonssupport.com

Algorithm
Waterhouse–Friderichsen Syndrome

CODES
ICD9 255.41 Glucocorticoid deficiency
ICD10 E27.1 Primary adrenocortical insufficiency

CLINICAL/SURGICAL PEARLS
Addisonian crisis: is acute, life-threatening shock.
– 5 S’s for treatment of Addisonian crisis
– Salt, Sugar, Steroids, Support for precipitating cause
– Classic triad: Hypotension, Hypertension, Azotemia
– Use “stress dose” steroids for patients with Addison disease undergoing surgical procedures.
ADENOMATOID TUMORS, TESTICULAR AND PARATESTICULAR

Ramiro J. Madden-Fuentes, MD
Judd W. Moul, MD, FACS

DIAGNOSIS

HISTORY
- Duration of lesion and size
- Interval growth
- Associated pain, dysuria, tenderness — epididymitis
- Prior malignancy or scrotal pathology
- Exposure to tuberculosis (TB)
- History of sarcoidosis, histoplasmosis
- History of urinary tract infection or sexually transmitted infection
- Recent GU manipulation — bacillus Calmette-Guérin (BCG) instillation

PHYSICAL EXAM
- Scrotal exam — Identify location of mass — single or multiple
  - Evaluate for varicocele or hydrocele
  - Compare with contralateral scrotal contents
  - Evaluate if fixed, mobile, indurated, or encroaching on other structures
  - Evaluate for spermatic cord involvement
- Inguinal exam — Evaluate for lymphadenopathy
  - Hernia

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Tumor markers if concern for testicular mass — α-fetoprotein (AFP), β-human chorionic gonadotropin (β-HCG)
- Lactate dehydrogenase (LDH)
  - Purified protein derivative (PPD) if TB suspected
  - No specific labs to diagnose adenomatoid tumors

Imaging
- Scrotal ultrasound
  - Solid vs. cystic
  - Location — testicular or paratesticular
  - If located in the tunica albuginea can grow into the testicular parenchyma and resemble a testicular malignancy
    - Vascular or avascular

DIFFERENTIAL DIAGNOSIS

Benign tumors of epididymis:
- Leiomyoma
- Papillary cystadenoma (associated with von Hippel-Lindau syndrome)
- Lipomas
- Hamartomas
- Adrenal cortical adenomas

Malignant tumors of the epididymis:
- Sarcoma (rhabdomyosarcoma, leiomyosarcoma, fibrosarcoma, liposarcoma)
- Melanotic neuroectodermal tumor of the epididymis
- Extension of primary testicular tumor
- Metastatic tumor to epididymis
  - Urologic (prostate, kidney)
  - GI (stomach, colon, carcinoid, pancreas)
- Other lesions of the epididymis
  - Granuloma (sperm, TB, sarcoidosis)
  - SpERMatocele
  - Epididymitis
  - Epidermoid inclusion cyst
  - Epididymal abscess
### Adenomatoid Tumors, Testicular and Paratesticular

**Treatment**

**General Measures**
- Excision via inguinal approach – for benign lesions
- Epididymitis – consider sexually transmitted infection as source in young men and treat accordingly (see Sexually Transmitted Infections section)

**Medication**
- First Line: N/A
- Second Line: N/A

**Surgery/Other Procedures**
- Excision of suspicious lesion via inguinal approach with proximal vascular control
- Frozen section
- If positive for malignancy, radical orchiectomy
- Further surgical therapy guided by pathology but may include retroperitoneal lymph node dissection if rhabdomyosarcoma

**Additional Treatment**
- Radiation Therapy: N/A
- Additional Therapies: N/A
- Complementary & Alternative Therapies: N/A

**Ongoing Care**

**Prognosis**
Adenomatoid tumors are uniformly benign with no well-documented cases of true invasion, metastasis, or recurrence after excision (3)[C]

**Complications**
Scrotal hematoma, pain, infection

**Follow-Up**
- Oncologic follow-up if malignant disease
- Patient testicular self-exam

**Patient Resources**

- 222.3 Benign neoplasm of epididymis
- 222.8 Benign neoplasm of other specified sites of male genital organs
- ICD10: 229.8 Benign neoplasm of other specified male genital organs
  - 229.20 Benign neoplasm of unspecified testis
  - 229.30 Benign neoplasm of unspecified epididymis

**Clinical/Surgical Pearls**
- Adenomatoid tumors are benign with no reported metastasis.
- Excision via inguinal approach with proximal vascular control preferred.
- Treatment for epididymitis is guided by risk of sexually transmitted infections as a source.
- Ultrasound is important to delineate a testicular vs. paratesticular origin of the mass.
**ADRENAL ADENOMA**

Aaron G. Boonjindasup, MD, MPH
Raju Thomas, MD, MHA, FACS

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- Extent of endocrine evaluation in patients with adrenal adenoma is controversial. Basic screening consists of:
  - Basic metabolic panel (BMP)
  - If elevated K+ and patient also hypertensive may be aldosterone-secreting lesion
  - Plasma metanephrines: Most sensitive test for pheochromocytoma
  - 24-hr urine cortisol
  - Low-dose dexamethasone suppression test to rule out SCS if suspected clinically
- Complete endocrine evaluation should be performed if findings on examination and history suggest excess of specific hormone or if positive findings found on screening examination

**Primary hyperaldosteronism (Conn syndrome)**

- Basic metabolic profile
  - Hypokalemia, alkalosis, HTN
  - Aldosterone: Renin ratio
- Values that define a positive screen subject to lab variability: be < 30 suggested by NIH as cut-off for positive aldosteronemia to renin ratio and indicates need for confirmatory testing
- Confirmatory testing for hyperaldosteronism
  - 3-day oral sodium-loading test—high sodium diet for 3 days followed by 24-hr urine measurements of aldosterone, sodium, and creatinine
- + test = 24-hr aldosterone > 12 mg/d
  - Captopril suppression test may be used for patients with cardiac and renal disease which prohibit sodium loading
- Cushing syndrome
  - 24-hr urine cortisol > 100 mg
- If equivocal, perform low-dose dexamethasone suppression test
  - 1 mg dexamethasone at 11 pm
  - Plasma cortisol between 8 AM and 9 AM
- Normal: Cortisol ≤ 15 pg/mL – ACTH dependent
  - Loss of signal between in- and out-of-phase images (microscopic fat-sensitive sequence)
- If screening: Stop tricyclic antidepressants, in patients also on antidepressants
- Phenoxybenzamine for patients also on alpha-blocker
- Captopril suppression test may be used for patients with cardiac and renal disease which prohibit sodium loading

**DIAGNOSIS**

**History**

- Determine history of hypertension, obesity, and glucose intolerance
- Suggestive of Cushing syndrome or adenocortical carcinoma
- Hypertension and history of hypokalemia
- Aldosterone-producing adenoma
- History of malignancy
- Patient medications (“spoilage” for hypertension)

**Physical Exam**

- Blood pressure and heart rate
- Look for stigmata of Cushing syndrome
- Hirudin, oilogonemia, easy bruising, acne, muscle weakness, truncal obesity, buffalo hump, purple striae

**Alert**

- Subclinical Cushing syndrome (SCS) can occur where abnormalities of the hypothalamic–pituitary–adrenal axes exist in the absence of overt signs and symptoms of Cushing syndrome
- May occur in 5–24% of patients with incidentally discovered adenomas
- May not be clinically evident following standard screening for cortisol hypersecretion
- 1 mg overnight dexamethasone suppression test most sensitive for SCS
- Should be performed in ALL patients with adrenal mass and metabolic syndrome

**Imaging**

- Adrenal adenoma: Small, well-defined, homogeneous
- Size criteria important
  - ≤ 5 cm usually benign
  - ≥ 6 cm – 25% malignant
- May occur in 5–24% of patients with incidentally discovered adenomas

**Diagnostic Procedures/Surgery**

- Adrenal biopsy or fine needle aspiration may be performed in select cases
- Reserved for differentiation of metastatic disease and benign lesion
- May not be able to differentiate between benign from malignant adrenocortical tumor
- Rule out pheochromocytoma with plasma metanephrines screening before performing biopsy on an adrenal mass

**Pathologic Findings**

- Aldosterone-producing adenoma
- Spironolactone bodies – eosinophilic laminated collagenous inclusions
- Found after treatment with spironolactone
- Cortisol-producing adenoma
- Vacuolated neoplastic cells
- Metanephrine-positive
- Bilateral adenomas
- Fungal, TB, histoplasmosis
ADRENAL ADENOMA

Differential Diagnosis
- Adrenal cortical carcinoma (up to 80% functional)
- Adrenal hemorrhage
- Adrenal myelolipoma
- Adrenal myelolipoma
- Adrenal lymphoma
- Adrenal metastasis
- Neuroblastoma
- Pheochromocytoma
- TLE, or other infectious cause

Treatment

General Measures
- Based on functional status and size of lesion
- Correct hyperkalemia and electrolyte abnormalities.

Medication

First Line
- For hormonally active adenomas in patients who refuse surgery or have contraindications to surgery
  - Cortisone
  - Spironolactone, eplerenone
  - Aldosterone receptor antagonists in the distal convoluted tubule (DCT)
  - 2nd line – Amiloride, triamterene
  - Inhibitors of OCT aldosterone sensitive sodium channels
- Cushing syndrome
  - Amilorides
  - Blocks the 1st step in cortisol synthesis (Shatzl and preprenolone)
  - Metopronol
  - Blocks the final step in cortisol synthesis (11-deoxycortisol to cortisol)
- Adrenal hemorrhage
  - IV fluids
- Adrenal adenomas
  - 1st step in cortisol synthesis

Second Line

N/A

Surgery/Other Procedures

- Surgical indications
  - Hormonally active masses
  - Any masses > 5 cm (25% of masses > 6 cm are assumed to be adrenal cortical carcinoma)
  - Masses with suspicious imaging characteristics of carcinoma
  - Hemorrhage, irregular borders, HU > 20
  - Laparoscopic and robotic approaches are described, but may have limitations with larger lesions
  - Retrosurgical approach possible for both open and laparoscopic surgery may reduce ileus
- Postoperative stress dose steroids indicated during unilateral adrenalectomy for cortisol producing adenomas and may be indicated for patients with SCS
- Prophylactically: 50 mg hydrocortisone IV q8h postop day 1

Steroid supplementation will be needed after adrenalectomy for cortisol-producing tumors and suppressed HPA recover (median of 15 mo)
- Postoperatively (POD 2): Hydrocortisone 20 mg PO qAM, 10 mg qAM
- Hydrocortisone slowly tapered over 3 mo to 10 mg daily
- AM cortisol should be measured and repeated until > 10 ng/dL
- Confirm recovery of HPA with cosyntropin test
  - Monitor for electrolyte disturbances with BMP and postoperative AI in patients with hormonally active tumors and/or SCS
- Acute AI (-addison state)

Alert

This is a life-threatening condition often preceded by hypotension unresponsive to fluid resuscitation.
- May occur in the postoperative state in the setting of cortisol-secreting lesion with downregulated cortisone adrenocortical function, and in patients with previous contralateral adrenal resection or due to concurrent illness or infection
- Other non-specific symptoms may include abdominal pain, salt craving, nausea, vomiting, fatigue, and fever
- Electrolyte abnormalities such as hyperkalemia or hyperaldosteronism and other laboratory abnormalities such as anemia, leukocytosis, or eosinophilia may also be found
- Prolonged use of steroids may increase risk of postoperative adrenal insufficiency

May begin steroid replacement if high clinical index of suspicion
- Diagnosis Obtain AM serum cortisol and ACTH level:
  - Normal > 10 ng/dL, low-normal (3.4–10 ng/dL), AI < 3 ng/dL
  - Confirmatory testing with evaluation of response to ACTH stimulation (cosyntropin test)
  - Measure serum cortisol at baseline
    - Give cosyntropin 0.25 mg IV
    - Measure serum cortisol at 60 min after dose
  - Adequate response: Cortisol > 18 pg/dL
- If acute AI is highly suspected, don’t wait for result before treating:
  - Give 2–3 0.1 D5 NS quickly and 4 mg dexamethasone IV
  - Use dexamethasone because IV cortisol will interfere with the diagnosis later during hospitalization
- Maintenance therapy:
  - Hydrocortisone 30 mg/d
    - Fludrocortisone 0.05–0.1 mg/d

Complications

- Hypertension
- Diabetes mellitus
- Atherosclerosis
- Prior wound healing
- Nephrotic syndrome
  - 14% of patients with Cushing syndrome – due to hypertension
- Adrenal insufficiency (Addison disease)

Follow-up

Patient Monitoring
- Nonfunctioning benign adrenal mass can be followed with physical and radiologic examinations
  - > 20% show enlargement > 1 cm
- No guideline on growth velocity on surgical treatment

References

Codes

ICD9
- 115.1 Benign neoplasm of adrenal gland
- 253.0 Cushing’s syndrome
- 253.10 Cushing’s syndrome

ICD10
- D55.00 Benign neoplasms of unspecified adrenal gland
- E82.4 Pituitary-dependent Cushing’s disease
- E26.01 Cushing’s syndrome

Clinical/Surgical Pearls

- Adrenal lesions should be surgically treated if > 5 cm or if functional active.
- No guideline on normal growth velocity for adrenal lesions.
- Melanoma, lung, breast, colon, and renal cell cancers have metastatic predilection to adrenal gland.

ONGOING CARE
- Unilateral Cushing syndrome can be fatal due to cardiovascular, thromboembolic, or hypertensive complications or infection
- Surgical removal of hormonally active adenomas is usually curative

Prognosis

- Unilateral Cushing syndrome can be fatal due to cardiovascular, thromboembolic, or hypertensive complications or infection
- Surgical removal of hormonally active adenomas is usually curative
ADRENAL CORTICAL CARCINOMA
John M. Lacy, MD, FACS
Stephen E. Strup, MD, FACS

DIAGNOSIS

HISTORY
- Most common symptoms are related to excess cortisol production (Cushing’s syndrome) in 50–60%, then virilization (20%), or mixed syndromes (20–30%)
- History of onset of symptoms ≤ 12 mo is suspicious for ACC
- Constitutional symptoms: - Weight loss, melasma, weakness, nausea, or vomiting usually associated with poor prognosis
- In children, suggested by generalized weight gain and delayed linear growth
- Nonfunctional tumors may be larger and present with mass effect
- Painful or palpable mass
- Lower extremity edema
- Urinary obstruction
- Budd-Chiari syndrome
- GI symptoms
- Hyperaldosteronism (primary)
- Hypertension
- Hypercalcemia
- Renal failure
- Incidental finding during imaging workup for other malignancies
- Difficult to distinguish between benign and malignant tumors

PHYSICAL EXAM
- Palpable abdominal mass
- Palpable supraclavicular lymph nodes
- Constitutional symptoms:
  - Weight loss, malaise, weakness, nausea, or vomiting
  - Constitutional symptoms: - Weight loss, melasma, weakness, nausea, or vomiting

DIAGNOSTIC TESTS & INTERPRETATION
Lab Tests for glucocorticoid excess (minimum 3 out of 4 tests)
- Dexamethasone suppression test
- 24-hr urinary free cortisol
- Basal cortisol (serum)
- ACTH (plasma)

 Sexual steroids and steroid precursors:
- 17-OH-progesterone (serum)
- Testosterone (serum)
- 17-β-estradiol
- 24-hr urine steroid metabolite exam

Metabolic bone disease:
- Parathyroid hormone
- 25-hydroxyvitamin D
- Bone mineral density (BMD)
- Bone scan

DIAGNOSTIC PROCEDURES/SURGERY
- CT of abdomen is preferred initial study in patients with ACC
- Differentiation between benign and malignant tumors
- Imaging:
  - CT of abdomen is performed initial study in patients with ACC
  - Benign tumors
  - Homogeneous appearance with well-delineated margins
  - Generally < 4–6 cm, smooth and round or oval contour
  - < 10 HFU or rapid washout of contrast < 15 min
  - Primary ACC:
  - Nonhomogeneous internal architecture
  - Irregular contour, invasion of surrounding structures
  - > 10 HFU or delayed washout of contrast > 15 min
  - MRI not proven to be more sensitive in differentiating malignant from benign tumors
  - Preferential imaging modality for evaluation of vena caval involvement
- ACC, Cushing’s syndrome: to the liver on T1-weighted images; heterogeneous signal intensity (brighter white) on T2-weighted images
- FDG-PET potentially useful in radiologically indeterminate lesions
- Bone scan if suspicious of skeletal metastases.

Pathologic Findings
- Macroscopic:
  - Lobulated, orange tumor with necrotic areas, calcifications, mitral valve vegetations
- Microscopic:
  - Weiss criteria for malignancy includes: ≥ 3 of the following:
    - High nuclear grade
    - Mitotic rate > 5/50/hpf
    - Atypical mitotic figures
    - Stromal invasion
    - Diffuse architecture in >33% of tumor
    - Necrosis
    - Vascular invasion
    - Sinusoidal invasion
    - Capsular invasion
- Antigen Ki-67: a promising new immunohistochemical marker
- Marker of proliferative activity
- Low-risk ACC: expressed in >10% of cells
- High-risk ACC: expressed in >10% of cells

DIFFERENTIAL DIAGNOSIS
- Functioning adrenal mass:
  - Adenoma, aldosterone, pheochromocytoma
- Nonfunctioning adrenal masses:
  - Hemorrhage, cyst, metastatic tumor, neurinoma
- Other: Renal cell carcinoma
TREATMENT

GENERAL MEASURES

Complete surgical excision is treatment of choice in resectable stage I or II tumors and children.

MEDICATION

- resectable stage I or II tumors and children
- Complete surgical excision is treatment of choice in

GENERAL MEASURES

- Laparoscopy
- Open approaches

Indications for surgery

- Clinical trials underway for targeted therapies
- If failed initial polychemotherapy regimen, may try
- If failed mitotane monotherapy, add cytotoxic

TREATMENT

Rapid development of symptoms is key to
distinguishing ACC from Cushing’s syndrome.

ADDITIONAL TREATMENT

- Adrenal crisis in patients who undergo surgery for
- Hydrocortisone must be administered during surgery
- Adrenal Mass Algorithm

ADRENAL INSUFFICIENCY, ACUTE (ADRENAL CRISIS)

Debasish Sundi, MD
Misop Han, MD

BASICS

DESCRIPTION

• Acute adrenal insufficiency (Sometimes called Addisonian crisis) symptoms are attributable to mineralocorticoid deficiency—there are many etiologies (1).
• Adrenal crisis is a subtype of acute adrenal insufficiency, it is a rapid and intense process triggered by a stressor such as surgery or sepsis.
• Symptoms of the Addison disease (chronic adrenal insufficiency) are difficult to recognize when the diagnosis of Addison disease is made when patients present with an acute crisis.
• Patient may present in hemodynamic compromise secondary to sodium and plasma volume depletion.
• Addisonian crisis should be treated immediately; treatment should not be delayed pending diagnostic test results.
• The disease usually results from bilateral adrenal cortex destruction. Destruction of the adrenal cortex causes a combined deficiency of glucocorticoids, mineralocorticoids, and adrenal androgens.

ALERT

Hypoglycemia and shock refractory to resuscitation with fluids and vasopressors should be considered Addisonian crisis and treated with intravenous steroids.

EPIDEMIOLOGY

Incidence

• Addison disease incidence: 0.6/100,000 per year
• Up to 0.7% of patients undergoing major surgery may experience adrenal insufficiency.

Prevalence

• Addison disease prevalence: 4–11/100,000
• ~11% of patients with septic shock manifest adrenal insufficiency.

RISK FACTORS

• Maternal: Bilateral adrenal hemorrhage from birth trauma
• Children: Pseudonodular or meningococcal septicaemia leading to acute hemorrageic destruction of both adrenal glands (Waterhouse–Friedrichsen syndrome)
• Adults: Adrenal crisis after surgical or septic stress, bilateral adrenal hemorrhage from systemic anticoagulation or coagulopathy disorder
• Special at-risk populations: Pregnant women, patients with idiopathic adrenal vein thrombosis, patients who have undergone nephrectomy or vascular embolization of adrenal medullas.
• Most common cause: Ruptured withdrawal of steroids from patients with adrenal atrophy secondary to chronic steroid use
Medications: Ketoconazole, amitriptyline, dexamethasone, histidine, phenytoin, rifampin

Genetics

• Hereditary factors may influence development of autoimmune adrenal insufficiency.
• Familial glucocorticoid insufficiency may be associated with a relative gene pattern.
• Addison disease has been associated with a variety of autoimmune diseases.

PATHOPHYSIOLOGY

• The adrenal cortex produces 3 classes of steroid hormones: Mineralocorticoids (aldosterone), glucocorticoids (cortisol), and androgens.
• Cortisol deficiency is primarily responsible for the manifestations of the crisis.
• Primary adrenal insufficiency is due to failure of the adrenal cortex.
• Secondary adrenal insufficiency is caused by failure of ACTH stimulation of the adrenal cortex.
• Chronic steroid administrations result in suppression of ACTH production via feedback inhibition.

ASSOCIATED CONDITIONS

Nearly 50% of patients with adrenals have some form of autoimmune disease: Hyperparathyroidism, poralal collapse, diabetes mellitus type I, hypothyroidism (Hashimoto thyroiditis), or hyperthyroidism (Grave disease).

GENERAL PREVENTION

• Perioperative stress dose steroid replacement when indicated (68).
• Low threshold to intervene with IV glucocorticoid replacement at early signs of fluid refractory hypotension.

DIAGNOSIS

HISTORY

• Prior steroid use:
  – Risk increase with minimum 20 mg prednisone or equivalent for at least 5 days within the past 12 mo
  – Patients receiving normal physiologic levels require the equivalent of 20 mg/day within 1 mo to recover normal adrenal function.
• Patients receiving glucocorticoids who have symptoms of adrenal insufficiency and have no role in the acute management of adrenal crisis.

• Acute adrenal crisis usually presents acutely with hypotension or hypotensive shock:
  – Clinical picture is more complex as a result of a mixture of preceding slow-onset symptoms and signs including abdominal pain, sepsis, pituitary or adrenal hemorrhage, surgery, or trauma.
  – Acute adrenal insufficiency should be considered in patients presenting in the emergency room with abdominal pain, nausea, diarrhea, hypotension, and fever.
  – The etiologies of hypotension is profound hypovolemia.
  – Hypotension may be one of the last signs (granulomatous because mineralocorticoid secretion is usually somewhat preserved in patients on chronic glucocorticoid replacement.

PHYSICAL EXAM

• Check blood pressure: Extreme hypotension and/or shock refractory to fluids and vasopressors suggests acute adrenal crisis.
• Vittorio often coexists with Addison disease:
  – Hyperpigmentation along palmar creases, buccal mucosa, pressure points, perianal mucosa, and nipple areolae.
  – Check for signs of generalized weakness and specifically muscle weakness.
  – Check for loss of axillary hair in females.
  – In adrenal crisis, patients may be hyper- or hypo-

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Plasma cortisol: Early AM levels <3 μg/dL
  – 90 mmol/L suggests diagnosis.
• Serum ACTH:
  – If low in the setting of low cortisol, patient has pituitary/hypothalamic disease.
  – If high in the setting of low cortisol, primary adrenal insufficiency exists.
• Electrolyte abnormalities: Decreased sodium and chloride levels, increased potassium levels, and an increased BUN/Cr ratio (reflecting hypovolemia)
  – Hypocalcaemia may be seen during adrenal crisis.
  – Hypocalcaemia may be seen with associated polyglandular failure and hypoparathyroidism.
• Exogenous glucocorticoids and melanocyte-stimulating hormone levels may be found.

ALERT

Labs are used only in the setting of nonemergent adrenal insufficiency and have no role in the acute management of adrenal crisis.

Imaging

• Abdominal x-rays may show adrenal calcifications if adrenal insufficiency is secondary to fungal or TB infection.
• Abdominal CT may show enlarged adrenal glands with TB infection or miliary mases.
• Adenals may be small secondary to idiopathic atrophy, autoimmune adrenalitis, or advanced TB.
• Adrenal gland hemorrhage or thrombosis may be seen.
ADRENAL INSUFFICIENCY, ACUTE (ADRENAL CRISIS)

Diagnostic Procedures/Surgery
- Rapid ACTH stimulation ( cosyntropin, a synthetic derivative of ACTH test)
  - Following injection of baseline serum cortisol, 250 μg of synthetic ACTH is administered IM or IV.
  - Plasma cortisol response is measured at 60 min.
  - Those with no response have primary adrenal failure. If the cortisol levels increase following synthetic ACTH injection, the adrenal insufficiency was secondary to pituitary dysfunction.

Pathologic Findings
- Autoimmune adrenal cortical infiltration
- Adrenal cortical infection/necrosis, with or without hemorrhage
- Metastatic carcinoma in adrenal gland
- Tuberculosis (transient of adrenal)
- Radiation effect

Differential Diagnosis
- Acute insufficiency (addisonian crisis) [1A]
  - Addison disease
  - Secondary adrenal insufficiency
  - Celiac disease
  - Syndrome of inappropriate ADH secretion
  - Severe nutritional deficiencies
  - Neuroblastoma
  - Pancoast-Taylor syndrome
  - Salt depletion nephritis
  - Bronchogenic carcinoma
  - Anorexia nervosa, depression

Treatment

General Measures
- In critically ill and decompensating patients, maintenance airway, and ensure adequate ventilation.
- Treatment instituted with IV fluid and maintenance dose of steroids, as needed
- In critically ill and decompensating patients, maintenance dose of steroids, as needed
- Stabilized.

Medication

First Line
- IV fluids: 0.9% NS or 5% dextrose in NS
- Hydrocortisone: 100 mg IV bolus immediately, followed by either 100 mg q8h or 10 mg/m2 continuous infusion for 2–3 days [25A].
- Dexamethasone: 2–8 mg as a single dose, this may be repeated as necessary

Second Line
- Pediatric considerations:
  - Hydrocortisone: 1–2 mg/kg/100 laser immediately, followed by 25–150 mg/d given in divided doses q8–q12h (infants and young children)
  - Gynecic considerations:
  - Start dosage on the low end of the dosing range due to greater frequency of impaired cardiac and renal function
  - Increased susceptibility to adverse effects such as glucocorticoids, diabetes, and osteoporosis with long-term therapy

Follow-up
- Patient Monitoring
  - Consider increase in steroid dosing when the patient has an episode of minor fever, infection, trauma, or physical stress.
  - Monitor blood pressure, weight, serum electrolytes, and blood glucose levels.
  - Monitor growth in pediatric patients.
  - Bone density, ophthalmologic exams.

- Adrenal Cellulitis
- Addison Disease
- Addison Disease (Adrenocortical Insufficiency)
- Algorithm [2]
- Adrenal Hemorrhage
- Adrenal Hypoplasia

Ongoing Care

Prognosis
- There is a high risk of morbidity and mortality associated with uncorrected acute crisis. May result in cardiovascular collapse if not recognized.
- Excellent long-term prognosis following immediate management of acute crisis and long-term maintenance therapy.

Complications
- Abdominal distention, peritonitis
- Edema, glaucoma, increased intraocular pressure
- Hypertension, hyperammonemia
- Immunosuppression
- Mood changes, weight gain, hirsutism

Additional Treatment

Surgery/Other Procedures
- Perioperative management during routine urologic surgery.
- Consultation with the preoperative physician for medical clearance and the procedural anesthesiologist is advised.
- Many patients taking low-dose prednisone (such as for autoinflammatory disorders) are able to undergo major surgery without any endocrine instability even without administration of intravenous stress-dose steroids [1B]. Incident fluid refractory hypotension in this group should be promptly treated with IV hydrocortisone.
- Patients with chronic adrenal failure and complete physical steroid replacement do generally require pericellular stress-dose steroids.
- Individualization of stress-doses and postoperative taper regimen is recommended.

Additional Reading

- Additional Reading
**ADRENAL MASS**

Kyle A. Richards, MD

**PATHOPHYSIOLOGY**

- Adrenal glands consist of an outer cortex and inner medulla and are part of the endocrine system
- Abnormal secretion of hormones = symptoms

**Adrenal cortex**
- Zona glomerulosa
  - Produces mineralocorticoid aldosterone
  - Regulates sodium and fluid homeostasis
  - Promotes exchange of potassium for sodium in distal tubules of kidney
  - Excess aldosterone = Cushing's syndrome
- Zona fasciculata
  - Produces glucocorticoid cortisol
  - Regulates cellular and glucose metabolism, immune processes, and other regulatory functions
  - Excess cortisol = Cushing's syndrome
- Zona reticularis
  - Produces adrenal androgens
  - Excess androgens = virilization
- Adrenal medulla
  - Produces catecholamines
  - Excess catecholamines = pheochromocytoma
- Addison's disease = adrenal insufficiency
- Usually not caused by adrenal masses

**ASSOCIATED CONDITIONS**

- See "Genetics"
- Hypertension (spontaneous or precipitated by postural change, anxiety, meds, and Valsalva
- Forceful heartbeat, pallor, tremor, headache, emotional and cognitive changes, proximal muscle weakness
- Facial rounding and plethora
- Central adiposity
- Thin skin, purple striae, and acne
- Hirsutism
- Gynecomastia or testicular atrophy

**DIAGNOSIS**

**HISTORY**

- Focus on symptoms suggestive of adrenal hyperfunction or malignant disease
- Cushing's syndrome
  - Weight gain
  - Easy bruising
  - Pervasive weakness
  - Emotional and cognitive changes
  - Opportunistic and fungal infections
  - Altered reproductive function
  - Pheochromocytoma
  - Episodic symptoms
  - Frustrated heartbeat, palpitations, tremors, headache, and diahrosis
  - Spontaneous or precipitated by postural change, anxiety, meds, and Valsalva
  - Primary hyperaldosteronism
  - Nocturia/polyuria (due to hypokalemia)
  - Muscle cramps and palpitations

**DIAGNOSTIC TESTS & INTERPRETATION**

- 24-hr urinary aldosterone excretion test while patient maintains high sodium diet
- Salt loading test

**BASICS**

**DESCRIPTION**

- An adrenal mass is generally considered to be an adrenal lesion > 1 cm
- Often found after abdominal imaging and often termed "adrenal incidentaloma"
- Rarely presents with acute or chronic symptoms

**INCIDENCE**

- Incidental adrenal mass (1,2,4)
  - Peak incidence at age 50–70
  - 2–6% bilateral
  - 1–2 per million persons per year
  - Bimodal age distribution: Age < 50–60% right side, 30–40% left side, 10–15% bilateral
  - Slightly higher incidence on left side
  - 2–6% bilateral
  - 1–2 per million persons per year
  - Bimodal age distribution: Age < 50–60% right side, 30–40% left side, 10–15% bilateral
  - Slightly higher incidence on left side
  - 1–2 per million persons per year
  - Bimodal age distribution: Age < 50–60% right side, 30–40% left side, 10–15% bilateral
  - Slightly higher incidence on left side

**GENETICS**

- Rare genetic syndromes may predispose to adrenal masses (1,4)
  - Beckwith–Weidemann syndrome
  -von Hippel–Lindau disease
  - McCune–Albright syndrome
  - Carney complex
  - Multiple endocrine neoplasia 2
  - Multiple endocrine neoplasia 1
  - Li–Fraumeni syndrome
  - Tuberous sclerosis
  - Von Hippel–Lindau syndrome

**PATHOLOGIES**

- 4% in patients undergoing CT scan
- 6% in autopsy series
- Increases with age (2,4)
  - 0.2% age 20–29, 7% age ≥ 70

**RISK FACTORS**

- Sex (1)
  - Malignant adrenal mass: Male > female (2:1)
  - Benign adrenal mass: Female > male (1.7:1)
- Aging
- Prior history of cancer especially melanoma, lung, breast, or kidney
- 50% of these adrenal masses are metastases

**DIAGNOSTIC TESTS & INTERPRETATION**

- 24-hr urinary free cortisol (5)
  - Aldosterone-to-renin ratio (morning)
  - 91–98% sensitivity and specificity
  - Serum cortisol > 5 μg/dL is diagnostic

**DIAGNOSTIC TESTS & INTERPRETATION**

- Cutoff for
  - 97% specificity
  - 95% specificity
  - 95%–99% specificity
  - 95%–99% sensitivity
  - 95%–99% specificity
  - 95%–99% sensitivity

**DIAGNOSTIC TESTS & INTERPRETATION**

- Confirmatory testing
- Saline infusion test
- 24-hr urinary aldosterone excretion test while patient maintains high sodium diet

**DIAGNOSTIC TESTS & INTERPRETATION**

- Cushing’s syndrome
  - Hypokalemia, hypoglycemic
  - 24-hr urinary cortisol (5)
  - 80 μg/24 h excludes diagnosis
  - Cortisol suppression testing
  - 1 mg dexamethasone at 11 pm and measure serum cortisol at 8 am the next day
  - Serum cortisol > 5 μg/dL is diagnostic

**DIAGNOSTIC TESTS & INTERPRETATION**

- Primary hyperaldosteronism
  - Nocturia/polyuria (due to hypokalemia)
  - Muscle cramps and palpitations
  - Adrenocortical carcinoma
  - Sporadic adrenal cancer
  - Cushing’s syndrome (see above)
  - Altered reproductive or sexual function
  - Hyperaldosteronism (see above)
  - Sex steroid-secreting tumor
  - Altered reproductive or sexual function
  - Metastatic cancer
  - History of intra-adrenal cancer
  - Medical history
  - Multiple endocrine syndromes
  - Medications such as exogenous steroids
  - Family history
  - See "Genetics"
**Adrenocortical carcinoma (CA)**
- Most commonly cortical origin
- Serum dehydroepiandrosterone (SHEA)
- Sex steroid-secreting tumor
- Serum testosterone and 17α-estradiol in women with uterine or men with feminization

**Pathologic Findings**
- Adrenal medullary tumors
- Adrenal cortical tumors (4)
- Adrenal insufficiency post adrenalectomy

**Diagnostic Procedures/Surgery**
- CT scan

**Hemorrhage**
- Cystic
- Hemorrhage
- Necrotic core
- Low density on T2-weighted imaging

**Concurrent adrenal hemorrhage**
- Hemorrhage
- Necrosis
- Calcification

**Differential Diagnosis**
- Cushing's Disease and Syndrome
- Adrenal Myelolipoma
- Adenal Adenoma and Cortical Carcinoma

**Pseudocyst**
- Cysts (pseudo)cyst, parasitic, epithelial- and endothelial (false cysts)

**Clinical Pearls**
- Assess all for biochemical function.
- Remove all adrenal masses > 5 cm.
- Do not biopsy pheochromocytoma.

**Radiation Therapy**
- Only for palliation of bone metastases from adrenal cortical carcinoma

**ADDITIONAL THERAPIES**
- N/A

**TREATMENT**

**General Measures**
- Observation, resection, or medical therapy
- Depends on size of lesion, functionality, malignant potential, and overall health of patient

**Medication**
- First Line
  - Cushing's syndrome (SC)
    - Amenoleptanide, metyrapone, ketoconazole
  - Phaeochromocytoma
    - Phenylephrine, propranolol
  - Primary hyperaldosteronism: Spironolactone
  - Adrenocortical carcinoma: Mitotane
- Second Line
  - Adrenocortical carcinoma
    - Etoposide, etoposide, 5-fluorouracil, doxorubicin, vincristine

**Surgery/Other Procedures**
- Should remove all functional adrenal masses
- Open surgery if large or locally advanced; evaluate for vein thrombus or adjacent organ invasion
- Minimally invasive surgery is now accepted
- Minimal invasive surgery is now accepted
- Remove masses > 5 cm; high malignancy risk
- Consider partial adrenalectomy for solitary adrenals, bilateral disease, familial syndromes

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- Only for palliation of bone metastases from adrenal cortical carcinoma

**ADDITIONAL THERAPIES**
- N/A

**Ongoing Care**

**Prognosis**
- Adrenocortical carcinoma: 33–72% of patients with primary hyperaldosteronism (PH)
- 10–15% recurrence rate after resection of phaeochromocytoma
- Adrenocortical carcinoma has poor prognosis
  - Mean survival 18 mo (418)
  - 3–yr survival 15–47%

**Complications**
- Adrenal insufficiency post adrenalectomy
- Unrecognized malignancy in phaeochromocytoma

**Follow-Up**

**Patient Monitoring**
- Conservative management principles (218)
  - Repeat imaging at 6, 12, and 24 mo
  - Repeat hormonal testing annually for 4 yr
  - If growth ≥ 1 cm or autonomous hormonal secretion, consider surgery

**Patient Resources**
- www.pheochromocytoma.org
- www.cancer.gov/cancertopics/types/adrenocortical
AMYLOIDOSIS, GENITOURINARY

Christopher Wright, MD
Mark L. Jordan, MD, FACS

DESCRIPTION

• Heterogeneous group of disorders with extracellular deposition of protein in aberrant fibrillar form:
  – Kidney, uterus, seminal vesicles, prostate, penis, and testicles can be involved
  – >50% of gentinourinary (GU) tract cases involve the bladder
  – Commonly forms “pseudotumors” in bladder, uterus, or renal pelvis
  • 25 structurally unrelated proteins known to cause amyloidosis
  • May be primary, secondary, or hereditary
  • May be organ limited or systemic

EPIDEMIOLOGY

Incidence

• Uncommon disorder and exact worldwide incidence is unknown
• In the United States appears to be stable at 6–10 cases per million person-years
• Age-specific incidence rates increase in each decade over age 40
  – Median age at diagnosis is 64 yr and <5% of patients are under age 40

RISK FACTORS

• Chronic and recurrent mucosal and submucosal inflammation
• Hemodialysis patients develop deposits in kidneys
• Chronic inflammatory disorders

Genetics

• Familial or hereditary amyloidosis exists
• Dozens of specific variations described
• Familial forms often do not present until adulthood
• Patients with immunoglobulin light chain (AL) amyloidosis frequently have chronic renal abnormalities but there is no single chromosome change that is diagnostic

PATHOPHYSIOLOGY

• More than 20 distinct low–molecular-weight proteins are recognized to form amyloid fibrils, the 2 most common being:
  – AA, formerly referred to as primary amyloidosis
  • Fibrils composed of fragments of monoclonal light chains
  • Aged patients may have amyloidosis alone or in association with other plasma cell dyscrasias (eg, multiple myeloma)
  – AL-amyloidosis
  • Fibrils composed of fragments of the acute phase reactant serum amyloid A
  • Usually reactive (secondary) to chronic inflammation
  • Thought to be a misleading event; misfolded variants are prone to self-aggregation
  – These become insoluble complexes that accumulate in tissues
  • Renal amyloid is often a glomerular deposition leading to nephrotic syndrome

ASSOCIATED CONDITIONS

• End-stage renal disease (ESRD) requiring dialysis
• Nephrotic syndrome
• Diabetes
• Multiple myeloma
• Familial Mediterranean fever (FMF)

• Hereditary inflammatory disorder characterized by severe attacks of abdominal pain in 95% of patients
• AA amyloidosis with renal failure is common

GENERAL PREVENTION

N/A

DIAGNOSIS

• Clinical presentation depends on the number and nature of the organs affected
• Even in patients with multiple-organ involvement, it is usually possible to identify 1 organ as the “dominant” site of involvement

HISTORY

• Non-specific symptoms such as fatigue and weight loss are common
• Patient on dialysis
• Family history of amyloidosis
• Chronic disease or inflammation
• Familial Mediterranean fever (FMF)

• Chronic disease or inflammation
• Cardiac:
  – 60% of patients
  – Signs/symptoms of heart failure
• Neurologic:
  – 20% with mixed sensory and peripheral neuropathy
  – Carpal tunnel syndrome
  – Liver:
  – 70% will have hepatomegaly
• Bladder:
  – Patients with amyloidosis in 75%
  – Nephrotic syndrome (rarely, frequency)
  – Clinically similar to bladder cancer
• Ureter:
  – Flank pain if obstruction
  – Anuria if bilateral amyloidosis
• Prostate:
  – Hematuria
  – Prostate:
  – Hematuria
  – Bladder outlet obstruction may be present

PHYSICAL EXAM

• Peripheral edema (nephrotic syndrome)
• Hepatosplenomegaly
• General medical no specific physical exam findings

DIAGNOSTIC TESTS & INTERPRETATION

• Proteinuria in 50–80%
• Renal failure in 50%
• Elevated liver function tests (cholestatic pattern)
• Diagnosis of AL amyloidosis requires evidence of a monoclonal proliferative disorder
• Serum or urine monoclonal (M) protein can be detected

Imaging

• CT or ultrasound (US) may demonstrate hydronephrosis secondary to obstruction (peripheral amyloidosis)
• Magnetic resonance imaging (MRI):
  – T2-weighted images are suggestive of amyloid deposition. Can be confused with prostate cancer invading into seminal vesicles or MRI for prostate biopsy

Diagnostic Procedures/Surgery

• Cystoscopy for hematuria
  – Lesions are difficult to distinguish from transitional cell carcinoma (TCC) without biopsy or resection
• Uroscopy or retrograde pyelogram for ureteral involvement
  – Bladder:
    – Abdominal fat pad aspirate or bone marrow biopsy have high success rates and are preferred sites of biopsy
    – Renal biopsy performed if former is negative with high suspicion
    – Will be positive in 90% of cases

Pathologic Findings

• Diagnosis requires histologic demonstration of amyloid deposits:
  – Congo red stain
  – Change under light microscope
  – Green birefringence under polarized light
  – Electron microscopy can be used to identify microfibrils
  – Immunohistochemical analysis aids in typing: Diagnosis of transthyretin type amyloidosis
  – If limits need for further evaluation as it identifies the amyloidosis as inherited
• Serum or urine monoclonal protein can be seen in radical prostatectomy specimen but the significance is unknown

DIFFERENTIAL DIAGNOSIS

• Bladder:
  – Difficult to distinguish from TCC without biopsy
• Ureter:
  – May be confused with stones or other causes of obstruction (eg, strictures)
• Nephrotic syndrome and glomerulonephritis
AMYLOIDOSIS, GENITOURINARY

TREATMENT

GENERAL MEASURES
- In AL amyloidosis treatment is aimed at reducing the production of monoclonal light chain precursor with chemotherapy or, occasional, radiotherapy or surgery of a localized amyloidogenic plasmacytoma
- In AA amyloidosis treatment is generally supportive with therapy directed at primary cause if identified

MEDICATION

First Line
- High-dose melphalan chemotherapy followed by autologous blood stem cell transplantation (2) – 25–67% complete hematologic response seen in single and multicenter trials
- Response far exceeds cyclic oral melphalan and prednisone (see 2nd line)
- Colchicine can be used in FMF to prevent proteinuria

Second Line
- Low-dose oral melphalan with prednisone in a cyclical fashion – Rarely results in complete hematologic response or reversal of amyloid-related organ dysfunction

SURGERY/OTHER PROCEDURES
- Renal transplant – Graft survival similar to matched controls without amyloidosis
- Recurs in graft in 20–33% due to continued activity of underlying disease
- TUR of bladder lesion with fulguration – Adjuvant intravesical DMSO has shown success in preventing recurrence (3)

ADDITIONAL TREATMENT

Radiation Therapy
Only rarely used for localized amyloidogenic plasmacytoma

Additional Therapies
- Supportive care
- Management of heart failure
- Salt restriction, diuretics, and treatment of secondary hyperlipidemia for nephrotic syndrome
- Analgesics for neuropathic pain

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Single institution experience of 421 patients who received high-dose melphalan with stem cell transplant shows event-free survival and overall survival of 2.6 and 6.3 yr, respectively (4)
- Long-term survival in those who develop renal failure remains poor – Ranges from 12–24 mo
- AA amyloidosis has better prognosis

COMPLICATIONS
See above

FOLLOW-UP

Patient Monitoring
- Bladder or urethra – Repeat periodic surveillance cystoscopies – Recurrence rates >50%
- Ureters – US or CT to monitor hydronephrosis

Patient Resources
Amyloidosis foundation (www.amyloidosis.org)

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Amyloidosis Imaging
- Bladder Tumors, Benign and Malignant, General Considerations
- Bladder Mass, Differential Diagnosis
- Filling Defect, Upper Urinary Tract (Renal Pelvis and Ureter)

ICD9
- 277.30 Amyloidosis, unspecified
- 277.39 Other amyloidosis

ICD10
- E85.3 Secondary systemic amyloidosis
- E85.8 Other amyloidosis
- N08 Glomerular disorders in diseases classified elsewhere

CLINICAL/SURGICAL PEARLS
- Both surgically and radiologically, genitourinary amyloidosis may mimic TCC in GU tract, therefore biopsy is needed.
- Additional far paper pad aspirate is preferred location to obtain biopsy, followed by bone marrow and finally kidney.
ANDROPause (Late-Onset Hypogonadism)

Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

**DESCRIPTION**
- Hypogonadism is a reduction in serum testosterone and other circulating androgens.
- Primary hypogonadism: Arias directly from testicular causes
- Secondary hypogonadism is where changes occur in hypothalamic-pituitary-testicular axis
- Late-onset hypogonadism is a gradual reduction in serum testosterone levels in elderly men; often referred to as “andropause.”

**EPIDEMIOLOGY**
- Estimates suggest more than 4.5 million elderly American men may be affected.
- % of men report moderate or severe scores consistent with hypogonadism on surveys (1)
- Thought to be underreported and undiagnosed in elderly males.

**RISK FACTORS**
- Decreases in serum testosterone occur naturally as part of the aging process.
- Genetics

**PATHOPHYSIOLOGY**
- Testosterone age-related declines vary by reported study:
  - Testosterone declined approximately 100 ng/dL (3.5 nmol/L) from age 20–80 yr
  - Testosterone fell 1.3% from age 40–79 yr
  - As age increases, there is:
    - Decreased number of Leydig cells within the testicle (site of testosterone production)
  - Decreased testicular responsiveness to LH (controversial)
  - Diminished in the amplitude of circadian release of T
  - Increased serum sex hormone binding globulin (SHBG)
    - Levels 1, therefore less bioavailable (functionally active) T
  - Relationship with cardiovascular (CV) disease is thought to be multifactorial
    - Nitric oxide (NO) is an important mediator in both CV health and erectile function

**ASSOCIATED CONDITIONS**
- Metabolic syndrome
- Diabetes mellitus
- Hypertension
- Tobacco abuse
- Sleep apnea
- Psychological disorders
- Social stress

**GENERAL PREVENTION**
- None

**DIAGNOSIS**

**HISTORY**
- Patients often complain of:
  - Fruity decreased grip strength, diminished gait speed, easy fatigue and exhaustion, unintentional weight loss, and low levels for physical activity
  - Decreased energy
  - Decreased mentation
  - Decrease in muscle mass and strength
  - Decreased libido
  - Erectile dysfunction
  - Loss of morning mictions
  - Increased visceral fat
  - Decrease in bone mineral density (osteoporosis and osteopenia)
  - Sleep disturbances
  - Depression
  - Metabolic syndrome
  - Poor glycemic control and diabetes mellitus
  - Cognitive/other CV disease

**PHYSICAL EXAM**
- Overall energy, muscle mass, and disposition
- Psychological evaluation
- Screen for clinical depression
- Include complete GU exam
- Coronary/CV disease
- Poor glycemic control and diabetes mellitus
- Metabolic syndrome
- Depression
- Sleep disturbances
- Diminution in muscle mass and strength
- Decreased libido
- Decreased mentation
- Decreased energy
- Frailty—decreased grip strength, diminished gait speed, easy fatigue and exhaustion, unintentional weight loss, and low levels for physical activity

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- TT: Diurnal variations so most accurate specimens are obtained in the morning (prior to 10:00 AM)
- “Normal” ranges vary widely by lab and definition of hypogonadism
- General accepted values although there is no clear lab definition of hypogonadism
  - <150 ng/dL with symptoms
  - <200 ng/dL without symptoms
- PDA research trial definition: <300 ng/dL
- Free testosterone
  - <50 pg/mL
- SHBG (sex hormone binding globulin)
  - Increases with aging, which leaves a greater percentage of protein-bound testosterone and lower levels of circulating free testosterone
  - Estradiol: Increased aromatization of testosterone to estradiol in adipose tissue
  - If abnormal TT levels, then check LH and prolactin

- Blood glucose to screen for diabetes mellitus
- PSA for prostate cancer screening
- Monitoring while on testosterone replacement therapy (TRT)
  - CBC to monitor hematocrit (risk of polycythemia)
  - PSA
  - Liver function tests

**Imaging**
- Bone density scan to evaluate for osteoporosis or osteopenia

**Differential Diagnosis**
- Acute critical illness (surgery, head trauma)
- Age-related decline (“Andropause”)
- Alcoholism
- Chronic illness (liver failure, chronic renal failure, hypertension, hypothyroidism, diabetes, sleep apnea, obesity, anorexia nervosa, depression, HIV)
- Hematologic (leukemia, lymphoma)
- Hypoestrogenism of the pituitary, Leydig cells
- Hypothalamic (hypothyroidism)
- Kallmann syndrome (congenital absence of GnRH)
- Klinefelter syndrome
- Medications: LHRH analogs/antagonists, glucocorticoids, anesthetics, estrogen, progesterin (eg, megestrol), chronic opioids, marijuana (controversial)
- Nissenson syndrome
- Pituitary infections, infarction, trauma, radiation (decreased LHRH production)
- Pituitary tumors, macroadenomas, hypophysitis
- Prader–Willi syndrome
- Sertoli cell-only syndrome
- Testicular failure (primary): Congenital or acquired anorchia, cystorchidism, mumps orchitis, radiation therapy, chemotherapy
- Testicular tumors

**DIAGNOSTIC PROCEDURES/SURGERY**
- Prostate biopsy if PSA and DRE are suspicious for prostatic cancer

**Pathologic Findings**

**BASICS**
TREATMENT

GENERAL MEASURES
- Can treat ED with phosphodiesterase-5 inhibitors if no contraindications
  - Avanafil
  - Sildenafil
  - Tadalafil
  - Vardenafil
  - Start at lowest dose and titrate up for efficacy

MEDICATION

First Line
- TRT (3)[B]
  - Intramuscular, transdermal (patches and gels), and buccal preparations. See Section I “Testosterone Replacement Therapy, General Principles” for specifics on TRT agents
  - Selection is dependent on patient/physician preference and feasibility
  - Considerations in the older male: The American Geriatrics Society (AGS) lists testosterone in the Beers Criteria as a medication to generally avoid in older adults because of potential for cardiac problems and men with personal history of prostate cancer (4)[A]
  - The choice of TRT should be individualized on specific clinical needs
  - Absolute contraindications: Personal history of breast cancer or untreated prostate cancer
  - Relative contraindications: Polycythemia, BPH causing urinary retention, treated prostate cancer

Second Line
- N/A

SURGERY/OTHER PROCEDURES
Men with primary erectile dysfunction complaints can discuss surgical placement of penile prostheses, use of vacuum erection devices, or vasoactive intracavernosal injection therapy

ADDITIONAL TREATMENT
- Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- Weight loss
- Weight loss
- Phytotherapies: Limited research on safety and efficacy of herbal medications
- Limited data on ability of any OTC supplement to influence T levels

ONGOING CARE

PROGNOSIS
- TRT is associated with improved responses in many areas
  - Quality of life
  - Mood and affect
  - Sexual function and libido
  - Cognitive function
  - Glycemic control

COMPLICATIONS
- Prostate cancer diagnosis or progression of disease
- Polypharmacy
  - Potential for cardiac and cerebral vascular events

FOLLOW-UP
- Patient Monitoring
  - Hemoglobin and hematocrit
  - Bone mineral density
  - DRE and PSA for prostate cancer screening
  - Continued monitoring of testosterone levels
  - Overall men’s health issues
  - Blood glucose
  - Serum lipids
  - Overall cardiovascular health

Patient Resources
- Urology Care Foundation AUA www.urologyhealth.org/urology/index.cfm?article=132

CODES

ICD9
- 253.4 Other anterior pituitary disorders
- 257.2 Other testicular hypofunction

ICD10
- E23.0 Hypopituitarism
- E29.1 Testicular hypofunction

CLINICAL/SURGICAL PEARLS
Treatment is based upon symptomatology more than lab values.
ANORECTAL MALFORMATIONS: IMPERFORATE ANUS, CLOACA, AND UROGENITAL SINUS ANOMALIES

Youngae Im, MD
Sang Won Han, MD

BASICS

DESCRIPTION
- Anorectal malformations (ARMs) are a spectrum of congenital anomalies involving the anorectal and urogenital systems, such that the anus and distal rectum are often absent.
- Imperforate anus: Absence of an anus, typically with a fistula between the rectum and lower urinary tract.
- Persistent urogenital sinus (UGS) is seen in 4 entities: (1) Urogenital sinus anomalies (UGS); (2) Pure UGS. With normal external genitalia; (3) Cloaca: In females, a common channel between lower urinary tract, vagina, and rectum; (4) Female eunuchosity

EPIDEMIOLOGY
Incidence
- ARM: 1 in 5,000–5,000 live births
- Cloaca: 1 in 50,000–100,000 live births
- UGS: 1 in 500 live births
- Incidence of ARM in the setting of genetic disease is about 5–10%

Prevalence
N/A

RISK FACTORS
- Proposed association with in utero vascular accidents, maternal diabetes and obesity, maternal ingestion of thalidomide, phenytoin, and caffeine
- Some degree of heritability, as incidence of subsequent children having ARM is 1%

Genetics
- ARM found in certain congenital syndromes with associated genital abnormalities (2)
  - Trisomy 21: Imperforate anus without fistula
  - Microdeletion of chromosome 22q11.2
  - Familial inheritance pattern: ARM with a rectovesical or rectovestibular fistula, almost 15% had a positive family history for an ARM
  - Currarino Trio: ARM, sacral agenesis, presacral mass (or meningocele); autosomal dominant
  - Tessier-Blocks syndrome: ARM, external ear abnormalities, hearing loss, polydactyly, renal anomalies; autosomal dominant
  - Cat eye syndrome: ARM, coloboma, presacral tail, heart defects, urinary tract abnormalities, mental retardation

PATHOPHYSIOLOGY
- Classic theory: The anorectal septum (mesodermic) fails to grow caudally to meet the lateral fetal folds to divide the cloacal membrane (endoderm and ectoderm) into the anterior urogenital membrane and the posterior anal membrane.
- Alternative theory: A mesenchymal mass displaces the dorsal cloacal membrane anteriorly, preventing its joining with the field gut.

ASSOCIATED CONDITIONS
- About 50–67% of all ARM are associated with other anomalies
- In general, the higher the ARM, the more likely there are associated anomalies
- Can occur as an isolated abnormality or as part of a syndrome:
  - VACTERL: Vertebral, anorectal, cardiac, tracheoesophageal fistula, renal, limb anomalies
  - Spinal and bony anomalies are present in 33–50% of ARM:
    - Tethered cord in 20–30%
    - Scoliosis, the most common vertebral anomaly
- Genitourinary abnormalities are common in ARM, but must not be diagnosed until puberty or adulthood
  - Duplicated vagina with septum
  - Absent vagina, vaginal atresia
  - Retractile urethra
  - Hydrometrocolpos in UGS associated with CAH
- Cardiovascular abnormalities are present in 10–30% of ARM:
  - Atrial septal defects and ventricular septal defects are most common
- Tracheoesophageal fistula (TEF) and esophageal atresia (EA) occur in 5–10% with ARM
  - 15% had a positive family history for an ARM

GENERAL PREVENTION
- International Consortium on Anorectal Malformations aims to identify genetic and environmental risk factors in ARM.
- No prevention reduction strategies are currently available.

DIAGNOSIS

HISTORY
- Perianal diagnosis: Low sensitivity/specifcity
  - Dilated colon, oligohydramnios, and distended vagina on prenatal US may be signs of ARM
  - Antenatal findings suggestive of cloacal anomaly:
    - Transient fetal ascites with bilobed or trilobed pelvic cystic structures
    - Bilateral hydrocolonoscopy or oligohydramnios
  - Lower level ARM and UGS may go undiagnosed in newborn until later symptoms develop:
    - Constipation, abdominal distension in rectal atresia, anorectal stenosis
    - Urinary incontinence and/or incontinence in UGS

PHYSICAL EXAM
- Thoroughly examine the perineum to determine number and position of orifices:
  - Perineum flattened in higher level ARM
  - Assess the genitalia: rule out hypospadias, cryptorchidism, chordee
  - Assess vesicourethral: Look for scrotal anomalies
  - Rule out associated pathologies:
    - Cardiac auscultation for murmur
    - Urethrogram: Pull back catheter
  - It may take up to 24 hr for signs of fistula to be evident

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Urinalysis: Abnormal if fistula to urinary tract
  - 17-hydroxy-progesterone in UGS with virilization to rule out CAH
  - Karyotype if ambiguous genitalia

Imaging
- Studies to determine level of ARM:
  - Prone, cross table lateral plain film
  - Should be performed at 24 hr after birth to allow enteric gas to reach the most distal area of the colon
  - Distance between rectal gas shadow and perineal opening measured
- Abdominal US: Evaluate bilateral kidneys, bladder, and urogenital structures
- Voiding cystourethrogram (VCUG)/urogram: Evaluate presence of VUR as well as relation of urinary tract to rectum (and to urogenital structures)
- Cystoscopy: Distal to mucosal fistula and proximal to colostomy to evaluate colonic anal and its relation to other pelvic structures prior to definitive surgery
- Spinal imaging:
  - Spinal US prior to 6 mo of age
  - Spinal MRI after 6 mo of age

Diagnostic Procedures/Surgery
- ECMO: Extracorporeal memmbrane oxygenation
- In general, the higher the ARM, the more likely there are associated anomalies
- UGS: Urogenital sinus anomalies
  - Pure UGS: With normal external genitalia

Pathologic Findings
- Rule out associated pathologies:
  - Cardiac auscultation for murmur
  - Urethrogram: Pull back catheter
Differential Diagnosis
- Classification systems for ARM (5):
  - Wingpread classification: Traditional “low,” “intermediate,” or “high”-ARM
  - Penile classification: Based on the presence and position of the fistula
  - Krickenbeck anatomic classification: An anatomic description of ARM, type of surgical procedure performed, and postop assessment of bowel movements, constipation, and soiling
  - Lesions in the male: Classifying patients (a) into low-lying or higher lesions have important clinical implications with regard to their treatment and prognosis
  - Imperforate anus without fistula, rectal atresia, neorectal fistula
  - Recto posterior urethral fistula
  - Rectovestibular fistula
  - Lesions in the female:
    - In cases of urinary retention, cutaneous vesicostomy may be necessary as newborn
    - In cases of hydrometrocolpos, vaginotomy may be performed, and postop assessment of bowel movements, constipation, and soiling
    - Diverting colostomy with mucous fistula needed in cases of imperforate anus without fistula, rectal atresia, neorectal fistula

TREATMENT

General Measures
- Newborn should not be given any enteric intake and should have nasogastric suction
- Should follow through puberty and child-bearing issues

Medication
- Antibiotics are non-specific and perioperatively
- Prophylactic antibiotics continued at least until VUR IV antibiotics neonatally and perioperatively

Surgery/Other Procedures
- Newborn should have nasal gastric suction
- Should follow through puberty and child-bearing issues
- NGB in many ARM, but rarely due to surgery

Ongoing Care
- Close follow-up needed to manage long-term problems like fecal and urinary incontinence and associated urologic abnormalities
- Should follow through puberty and child-bearing age due to potential for hydrometrocolpos/chromatometra, infertility, ectopic pregnancy, delivery issues

Patient Resources
- http://www.pubmed.gov/anorectal-malformation-treatment

Anorectal Malformations: Imperforate Anus, Cloaca, and Urogenital Sinus Anomalies

  - Disorders of Sexual Differentiation
  - Exstrophy, Cloacal

ICD-9
- E96.1 Congenital malformation of intestine, unspecified
- 751.5 Other anomalies of intestine

ICD-10
- E25.0 Congenital anorectal disorders associated with anorectal malformations
- Q42.3 Congenital absence, atresia and stenosis of anus without fistula
- Q43.9 Congenital malformation of intestine, unspecified

Clinical/Surgical Pearls
- ARM usually requires neonatal surgical interventions and follow-up to obtain and maintain fecal and urinary continence.
ANORGASMIA, MALE
Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION
- Anorgasmia is defined as the complete inability to achieve an orgasm (the physical and emotional sensation experienced at the peak of sexual excitation) (1)
- In males, orgasm is typically associated with ejaculation (antegrade semen passage through the urethra)
- There is more robust literature in the female population with anorgasmia
- Also described in some references as orgasmic disorder, orgasmic dysfunction, or orgasmic inhibition
- Anorgasmia is often associated with delayed/inhibited ejaculation or anejaculation, although orgasm and ejaculation are separate phenomena
- Orgasm is a cerebrally mediated event, whereas ejaculation is localized to the genitourinary tract
- Must result in personal distress or interpersonal difficulty according to definitions by the DSM-IV-TR and the World Health Organization Second Consultation on Sexual Dysfunction (2)

EPIDEMIOLOGY
Incidence
- N/A

Prevalence
- Difficult to clearly report, as there is no clear definition of normal ejaculatory latency time
- In general, DE is reported at low rates in the literature, rarely exceeding 3% (3,4), but has been reported in up to 25% of clinical cohorts (2)

RISK FACTORS
- Advancing age
- Endocrinopathies (hypothyroidism, hypogonadism)
- Pelvic trauma/surgery (radical prostatectomy, retroperitoneal, bilateral sympatheticotomy)
- Pelvic radiation therapy
- Neuropathy (multiple sclerosis, diabetes mellitus, spinal cord injury)
- Secondary to medication (thiazide diuretics, tricyclic and selective serotonin reuptake inhibitor [SSRI] antidepressants, alcohol, gabapentin)

PATHOPHYSIOLOGY
- Unless a specific organic cause is noted (see Risk Factors), anorgasmia is associated with underlying psychological factors
- Fear, anxiety, hostility, and relationship difficulties
- It has been suggested to relate to orthodoxy of religious belief (ie, it is sinful to experience sexual pleasure)
- “Performance anxiety” may be a common cause
- May relate to men deriving greater arousal/enjoyment from masturbation than intercourse (2)
- Masturbatory frequency/style may be predisposing factors, as men with coital anorgasmia may report high levels of masturbation (2)
- Alcohol may transiently cause anorgasmia

ASSOCIATED CONDITIONS
- Anejaculation
- Delayed/inhibited ejaculation
- Depression
- Infertility

DIAGNOSIS

HISTORY
- Is the problem lifelong or acquired?
- Sexual history
- Establish the conditions (if any) where the patient is able to experience orgasm
- Assess the presence of life stressors or other psychological factors, the quality of the patient's nonssexual relationship with the partner

Medication use
- SSRIs and gabapentin have been implicated

PHYSICAL EXAM
- Genital exam to verify the presence and normality of testicles and epididymides bilaterally
- Secondary sexual characteristics and hair distribution
- Neurologic exam to assess genital sensation
- May not be contributory

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Serum morning testosterone level
- As indicated
  - Semen analysis
  - Semen culture
  - Urine culture
  - Urine cytology
  - Thyroid screen

Imaging
- Scrotal/transrectal ultrasound if indicated

Diagnostic Procedures/Surgery
- None

Pathologic Findings
- N/A

DIFFERENTIAL DIAGNOSIS
- Psychiatric distress (anxiety, depression)
- Retrograde ejaculation
- Anejaculation
- Delayed ejaculation
- Reduced ejaculation
- Penile hypoesthesia

Genetics
- N/A
ANORGASMIA, MALE

TREATMENT

GENERAL MEASURES
- Treatment should be etiology specific
- May include patient/couple psychoeducation and/or psychosexual therapy
- Pharmacologic treatment has met limited success

MEDICATION
First Line
- None currently FDA approved

Second Line
- No drugs are specifically approved for treatment of anorgasmia, so any treatment is off-label
  - Cyproheptadine (increases cerebral serotonin levels)
  - Amantadine (stimulant of dopaminergic nerves)
  - Bupropion, buspirone, and yohimbine have been anecdotally employed to reverse SSRI-induced anorgasmia

SURGERY/OTHER PROCEDURES
- None

ADDITIONAL TREATMENT
- Radiation Therapy
- None

ADDITIONAL TREATMENT: Radiation Therapy
- None

ADDITIONAL THERAPIES
- Psychotherapy
- Masturbation retraining
- Education on revised sexual techniques which maximize arousal

Complementary & Alternative Therapies
- Yohimbine has utility in anecdotal reports

ONGOING CARE

PROGNOSIS
- Continued support/psychotherapy may be required
- Anorgasmia related to trauma/surgery, radiation therapy, and neuropathies may not be reversible

COMPLICATIONS
- None

FOLLOW-UP
- Patient Monitoring
  - N/A

Patient Resources
- N/A

REFERENCES

  - 608.89 Other specified disorders of male genital organs
- ICD10
  - P52.23 Male orgasmic disorder
  - N03.11 Retarded ejaculation

CLINICAL/SURGICAL PEARLS
- Anorgasmia is often associated with ejaculatory disorders.
- Unless a specific organic cause is noted, anorgasmia is associated with underlying psychological factors.
- Anorgasmia related to trauma/surgery, radiation therapy, and neuropathies may not be reversible.
- There are no approved pharmacologic treatments for anorgasmia.
Oligoanuria may result from 3 broad categories:
- Nephrotoxic medications
- Myeloma
- Hypertension
- Diabetes mellitus
- Congestive heart failure

Associated with a severe decrease in the glomerular filtration rate (GFR) compromising kidney’s main functions:
- Maintenance of body composition (such as fluid, acid-base, electrolyte content, and concentration)
- Excretion of metabolic end products and foreign substances (toxins, drugs, and diagnostic radiographic contrast)

**BASICS**

**DESCRIPTION**
- Anuria: urine output of < 0 mL/d
- Oliguria: urine output of 50 mL/d or < 50 mL/d
- Often the earliest sign of impaired renal function
- Associated with a severe decrease in the glomerular filtration rate (GFR) compromising kidney’s main functions:
  - Maintenance of body composition (such as fluid, acid-base, electrolyte content, and concentration)
  - Excretion of metabolic end products and foreign substances (toxins, drugs, and diagnostic radiographic contrast)

**Epidemiology**

**Incidence**
- Frequency depends on various clinical settings:
  - 1% at admission
  - 2–5% during hospitalization
  - 4–15% after cardiopulmonary bypass

**Prevalence**

**Risk Factors**
- Chronic kidney disease
- Congestive heart failure
- Diabetes mellitus
- Hypertension
- Myeloma
- Nephrotoxic medications

**GENETICS**

**Pathophysiology**
- Oliguria may result from 3 broad
- pathophysiologic processes: Prerenal, intrarenal, and postrenal causes

**Prevention**
- Pharmacologic responses that lead to decreased GFR:
  - Maintain GFR by afferent arterial dilatation and efferent arteriolar constriction (mediated by angiotensin II)

**Diagnosis**

**History**
- Age, gender
- Duration of symptoms
- Chronic kidney disease
- Diabetes mellitus
- Hypertension
- Cardiac disease
- Liver disease
- Organ transplantation

**Physical Exam**

**Diuretics**
- Burns, trauma, surgery

**Urinalysis**
- Normal, or hyaline casts
- Blood cell casts
- Tubular epithelial cells

**Lab**
- Serum electrolytes
  - Hyponatremia
  - Hyperkalemia
  - Hyperphosphatemia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Sodium, potassium, bicarbonate, creatinine, blood urea nitrogen, uric acid, calcium, magnesium, phosphorus, protein, cholesterol, triglycerides, glucose, lipid profile, hepatitis panel, antinuclear antibody, rheumatoid factor, prostate-specific antigen, prostate-specific acid phosphatase, urinalysis
- Urine indices
  - Protein: Fractional excretion of sodium (FeNa):< 1%, serum BUN/Cr ratio: < 20:1
  - Intravenous: Nefia: > 1%, serum BUN/Cr ratio: < 20:1
  - Postrenal: Nefia: > 1%, serum BUN/Cr ratio: > 20:1
Imaging
- Renal/bladder ultrasonography: 1st line in imaging, noninvasive, no radiation exposure
  - Hydronephrosis and hydrothorax
- Kidney stones
- Pyelocalyceal system
- Intravenous urography: To evaluate vascular/renal
- Nuclear renal scans (such as technetium 99 m mercaptoacetyltriglycine [MAG3]): To assess the adequacy of renal perfusion and obstructive uropathy
- Intravenous pyelography or intravenous contrast dye generally does not indicate as it may exacerbate renal injury

Diagnostic Procedures/Surgery
- Foley catheter placement: To rule out lower urinary tract obstruction
- Retrograde pyelography with cystoscopy: To define the site and cause of obstruction
- Renal biopsy: To determine intrarenal etiology
- Urodynamic study: To evaluate functional abnormality of the bladder (neurogenic bladder)
- Nuclear renal scans (such as technetium 99 m mercaptoacetyltriglycine [MAG3]): To assess the adequacy of renal perfusion and obstructive uropathy
- Voiding cystourethrogram: To evaluate vesicoureteral reflux
- Duplex Doppler ultrasound: To evaluate the patency of renal artery and vein
- Renal/bladder ultrasonography: 1st line in imaging, noninvasive, no radiation exposure

-- Uremic pericarditis
-- Refractory acidosis
-- Refractory volume overload
-- Refractory hyperkalemia

MEDICATION
First Line
- Parenteral fluids: Usually rapidly reversed following restoring renal perfusion
- Replace fluid with intravenous hydration or blood product transfusion
- Diuretics and low-dose dopamine
- Discontinue the nephrotoxic medications (NSAIDs, ARBs, ACEIs)
- Optimize cardiac output and volume status
- Intravenous: ATN is the most common cause
  - There is no single or sequence of interventions that will significantly improve renal function after onset of ATN [1][A]
  - Use of diuretics and low-dose dopamine
  - Increasing urine output does not shorten the duration of renal failure, decrease the requirement for dialysis or improve survival in patients with established oliguric ARF [2][A]
  - Diuretics may be given for a short length of time for volume control
  - Low-dose dopamine (1–3 μg/kg/min, intravenously) does not reduce mortality or promote the recovery of renal function [4][A]

SURGERY/OTHER PROCEDURES
- Obstructive uropathy: Usually responds to release of obstruction
- There is no single or sequence of interventions that will significantly improve renal function after onset of ATN [1][A]
- Inability to manage electrolytes and fluid balance
- Requirement for renal replacement therapy
- Mortality rate depends on the underlying cause and associated medical condition
- Identification and timely treatment of reversible causes are crucial because the therapeutic window may be small
- In most clinical situations, acute oliguria is reversible and does not result in permanent renal impairment
- Mortality rate depends on the underlying cause and associated medical condition
- Identification and timely treatment of reversible causes are crucial because the therapeutic window may be small
- There is no single or sequence of interventions that will significantly improve renal function after onset of ATN [1][A]

ONGOING CARE
PROGNOSIS
- Mortality rates depend on the underlying cause and associated medical condition
- In most clinical situations, acute oliguria is reversible and does not result in permanent renal impairment
- In most clinical situations, acute oliguria is reversible and does not result in permanent renal impairment
- Identification and timely treatment of reversible causes are crucial because the therapeutic window may be small

COMPLICATIONS
- Nephrotoxic medications (NSAIDs, ARBs, ACEIs)
- Optimize cardiac output and volume status
- Intravenous: ATN is the most common cause
- There is no single or sequence of interventions that will significantly improve renal function after onset of ATN [1][A]
- Use of diuretics and low-dose dopamine
- Increasing urine output does not shorten the duration of renal failure, decrease the requirement for dialysis or improve survival in patients with established oliguric ARF [2][A]
- Diuretics may be given for a short length of time for volume control
- Low-dose dopamine (1–3 μg/kg/min, intravenously) does not reduce mortality or promote the recovery of renal function [4][A]

FOLLOW-UP
Patient Monitoring
- Serial renal function testing for resolution
- Subsequent renal imaging study to confirm the resolution of prerenal obstruction

ANURIA AND Oliguria, ADULT
ANURIA AND OLIGURIA, PEDIATRIC
Jennifer A. Hagerty, DO

BASICS
DESCRIPTION
• Typically, 1st sign of impaired renal function
• Anuria: No urine output
• Oliguria: Significantly reduced urine volume
  – <1 mL/kg/h in infants
  – <0.5 mL/kg/h in children

EPIDEMIOLOGY
Incidence
• 10% of newborns in the NICU (1)[C]
• 2–5% of children in the ICU (1)[C]
• 10–30% of children undergoing cardiac surgery (1)[C]

Prevalence
N/A

RISK FACTORS
• Hypovolemia
• Intrinsic renal disease
• Urinary tract obstruction
• Glomerulonephritis
• Nephrotic medications

Genetics
Dependent on diagnosis

PATHOPHYSIOLOGY
Prerenal failure
• Most common cause of oliguria
• Hypoperfusion in otherwise normal kidneys
• Administration of nephrotoxic agents can precipitate oliguria when reduced renal perfusion is present

Intrinsic renal failure
• Associated with structural kidney damage including acute tubular necrosis (ischemia, drugs, or toxins), primary glomerular diseases, or vascular lesions
• Altered tubule cell metabolism leads to ischemia, then altered metabolism and subsequently cell death

Postrenal failure
• Obstructive uropathy
• Usually reversible with relief of the obstruction

ASSOCIATED CONDITIONS
• Pre-existing renal disease
• Obstructive uropathy

GENERAL PREVENTION
• Maintain adequate hydration
• Avoid nephrotoxic agents in children with underlying renal disease

DIAGNOSIS
HISTORY
• Age, sex
• Duration of symptoms
• Pre-existing renal disease
• Medications
• Symptoms of urinary tract obstruction
• Antecedent history
• Family history

PHYSICAL EXAM
• Signs of hypovolemia
  – Tachycardia
  – Hypotension
  – Decreased skin turgor
  – Dry mucous membranes
• Signs of hypervolemia
• Signs of obstructive uropathy
  – Palpable bladder or kidney
  – Urine leukocytosis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Urinalysis
  – Protein, red cells, casts: Possible glomerulonephritis
  – Low specific gravity: Possible acute interstitial nephritis or intrinsic renal disease
  – High specific gravity: Possible prerenal cause
  – Nitrate: Suggests infection
• Basic metabolic panel
  – BUN/Cr ratio: >20 suggests prerenal cause
  – Evaluate renal function and electrolyte balance

Imaging
• Renal and bladder ultrasound for hydronephrosis and bladder distention and thickening of the wall
  • VCUG for suspected bladder outlet obstruction
  • Nuclear renal scan for function, diastasis, and drainage

Diagnostic Procedures/Surgery
Placement of a urethral catheter

Pathologic Findings
Dependent on diagnosis

DIFFERENTIAL DIAGNOSIS
• Prerenal
  – Burns
  – Dehydration
  – Drugs
  – GI losses
  – Heart disease
  – Hemorrhage
  – Respiratory distress syndrome
  – Shock/leaks
• Intrinsic renal disease
  – Acute tubular necrosis
  – Exposure to nephrotoxins (drugs, myoglobin, uric acid)
• Congenital kidney disease
• Renal vascular abnormalities
• Glomerulonephritis
• Urinary tract obstruction
• Neoplastic bladder
• Posterior urethral valves
• Meatal stenosis
• Bilateral UPJ or ureteral obstruction or unilateral in a solitary kidney
• Bilateral obstructing calculi

TREATMENT
GENERAL MEASURES
• Treatment of the underlying cause
• Appropriate medical management for acid-base disorder, fluid imbalance, electrolyte imbalance (such as hyperkalemia, hyperphosphatemia, hypocalcemia)
• Strict volume monitoring of input and output
• Avoidance of nephrotoxic agents (NSAIDs, ARBs (angiotensin receptor blockers), ACEIs (angiotensin-converting enzyme inhibitors))

MEDICATION
First Line
• Hydration to optimize cardiac output and volume status

Second Line
• Diuretics considered if adequate intravascular volume status and patient remains oliguric
• Hemodialysis or peritoneal dialysis to be considered if severe electrolyte abnormalities or volume overload
**SURGERY/OTHER PROCEDURES**
Relief of obstruction with urethral catheter, ureteral stenting, or nephrostomy tube

**ADDITIONAL TREATMENT**
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
None

**ONGOING CARE**

**PROGNOSIS**
- Acute oliguria is often completely reversible if recognized and treated promptly
- Small increases in serum creatinine can be indicative of worsening outcome [26]

**COMPLICATIONS**
- Progression to permanent renal injury
- Infections secondary to uremia leading to impaired defenses
- Cardiovascular complications secondary to fluid overload and electrolyte abnormalities
- Neurologic changes: Confusion, lethargy, and seizures
- Gastrointestinal effects: Anorexia, nausea, and vomiting

**FOLLOW-UP**

**Patient Monitoring**
- Serial renal function testing until resolution of anuria/oliguria
- Imaging based on diagnosis
  - Monitor renal/bladder ultrasound for obstructive uropathy

**Patient Resources**
- American Society of Pediatric Nephrology: www.aspneph.com
- National Kidney Foundation: www.kidney.org

**REFERENCES**

**ADDITIONAL READING**

**See Also** (Topic, Algorithm, Media)
- Acute Kidney Injury, Adult
- Acute Kidney Injury, Pediatric
- Chronic Kidney Disease, Pediatric
- Posterior Urethral Valves
- Ureteropelvic Junction Obstruction
- Urinary Retention, Pediatric

**CODES**

**ICD9**
- 276.52 Hypovolemia
- 599.60 Urinary obstruction, unspecified
- 788.5 Oliguria and anuria

**ICD10**
- E86.1 Hypovolemia
- N13.9 Obstructive and reflux uropathy, unspecified
- R34 Anuria and oliguria

**CLINICAL/SURGICAL PEARLS**
- Prerenal oliguria is typically reversible with complete return of renal function within 24–72 hr.
- Avoid nephrotoxic agents in patients with underlying intrinsic renal failure.
AUTONOMIC DYSREFLEXIA
Michael J. Amirian, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION
Autonomic dysreflexia (AD) occurs in patients with spinal cord lesions at and above the 6th thoracic level (T6).

– Potentially life-threatening condition in response to noxious stimuli.

– Spinal cord lesions at and above the 6th thoracic level (T6) are most common causes to trigger AD

– Rapid, external BP elevation, bradycardia, headache, diaphoresis, sweating, nausea, and piloerection

EPIDEMIOLOGY
Incidence
Unknown

Prevalence
• ~85% of quadriplegic and high paraplegic individuals prone to AD in response to noxious stimuli

• More common in men than women

• Due to increased bladder outlet resistance

RISK FACTORS

– Male

– High spinal cord injury (SCI)

Genetics
None

PATHOPHYSIOLOGY

– Activation of sympathetic neurones in lateral horn of spinal cord causing unopposed reflex sympathetic activity

– Stimulate bladder or bowel distention and pain

– Vasodilatation and subsequent hypertension (HTN)

– In response, vagal nerve triggers bradycardia

– Vagal nerve is able to vasodilate above injury (flushing in face), but vessels below injury remain vasoconstricted

– Other symptoms of sympathetic activation

– Diaphoresis and piloerection

ASSOCIATED CONDITIONS
SCI

GENERAL PREVENTION

– Avoid rapid or prolonged bladder distention

– Maintain regular schedule of bowel emptying

– Monitor for pressure sores

DIAGNOSIS

HISTORY

– SCI or transverse myelitis at T6 or above

– Known for urologic causes

– Bladder distention

– Recent instrumentation

– Indwelling urethral or suprapubic tube

– Urinary tract infection (UTI)

– Nerve, urethral, or bladder calcification

– Epididymitis or orchitis

– Fracture

– Bladder outlet obstruction

– Hypertension

– Pheochromocytoma

– Brain stem tumors

– Malignant hypertension

– Renal, ureteral, or bladder calculi

– Urinary tract infection

– Indwelling urethral or suprapubic tube

– Recent instrumentation

– Male

– Females

– Pregnancy and labor

– Sexual intercourse

– Ingrown toenails

– Tight clothing

– Pressure sores

– Bowel distention

– Urodynamic testing

– Bladder distention

– Pressure sores

– Tight clothing

– Inguinal hernia

– Sexual intercourse

– Pregnancy and labor

– Symptoms may include blurred vision, nasal congestion, anxiety, HTN in this patient population

PHYSICAL EXAM

– BP often severely elevated and often accompanied by diaphoresis and piloerection

– A normal BP of 120/80 may actually represent “Bite and swallow” technique

– A BP 20–40 mmHg above the patients baseline

– Consider that the resting BP is decreased after SCI

– Flushing and profuse sweating above level of injury

– Skin congestion, anxiety

DIAGNOSTIC TESTS & INTERPRETATION

Lab

– Urinalysis and urine culture

– Evaluate for infection

– UTI can be a trigger for AD

Imaging

– CT of abdomen and pelvis

– Evaluate for urolithiasis if cause not apparent

– Urodynamic tests

– Evaluate bladder compliance

– Risk out persistently elevated bladder pressures

Pathologic Findings

None

DIFFERENTIAL DIAGNOSIS

– Brain stem tumors

– Paracoccyeal HTN

– Pheochromocytoma

– Preeclampsia

TREATMENT

GENERAL MEASURES

– Removal of triggering stimulus is the 1st step

– MINIMIZE noxious stimuli below level of injury

– Bladder drainage or bowel decompression

– If present, consider gentle Foley catheter irrigation with no more than 10–20 mL saline to make sure that the catheter is patent

– Monitor BP closely during acute episodes

– BP >150 mmHg requires urgent management to avoid severe complications

– Siting the patient upright might reduce BP

– Tadalafil) for erectile dysfunction

– Nitrates: Sub lingual nitroglycerine, apply 1”, 2% nitro paste

– Nitrates should be avoided in patients who may be using PDE-5 inhibitors (sildenafil, vardenaft, tadalafil) for erectile dysfunction

– Nifedipine 10 mg PO immediate release form

– “Bite and swallow” technique

– Captavil 25 mg IV

– Hydralazine or Labetalol 10 mg IV

– Chronic treatment with α-blockers may improve some symptoms of AD (T6)

– Doxazosin 2–8 mg PO QD

– Terazosin 2–8 mg PO QD

– Salmeterol 6.4 mg PO QD

– Allopurinol 10 mg PO QD

– Appropriate antibiotics if UTI suspected

Second Line

– Phenylephrine 10 mg PO BD

– Botulinum toxin injection into the detrusor

– For patients on intermittent catheterization to decrease bladder pressure

– Botulinum toxin injection into external sphincter

– For patients who wish to relieve pain to decrease voiding pressures

ALERT

Left untreated consequences of autonomic dysreflexia can cause seizures, intracranial bleeds, hypertensive encephalopathy, and death.

MEDICATION

First Line

– Acute episodes managed with nitrites or arterial dilators under closely monitored conditions

Second Line

– Doxazosin 2–8 mg PO QD

– Terazosin 2–8 mg PO QD

– Salmeterol 6.4 mg PO QD

– Allopurinol 10 mg PO QD

– Appropriate antibiotics if UTI suspected

– Phenylephrine 10 mg PO BD

– Botulinum toxin injection into the detrusor

– For patients on intermittent catheterization to decrease bladder pressure

– Botulinum toxin injection into external sphincter

– For patients who wish to relieve pain to decrease voiding pressures

ACUTE PHASE

– Intramuscular injection of glyceryl trinitrate

– Labetalol 100 mg IV

– Sildenafil 50 mg PO

– Hydralazine 10 mg IV
A

SURGERY/OTHER PROCEDURES
- Sphincterotomy or sphincter-stent prosthesis
  - Allows reflex voiding with low-pressure bladder emptying into a condom catheter (2)(A).
- Bladder augmentation
  - Only in patients with ability to catheterize
- Sacral rhizotomy
  - For severe cases (3)(B)

ADDITIONAL TREATMENT
Radiation Therapy
N/A
Additional Therapies
N/A
Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
Managed effectively will have little impact on patient

COMPLICATIONS
Intracerebral and subarachnoid hemorrhage

FOLLOW-UP
Patient Monitoring
- Clean intermittent catheterization
  - Frequent (at least 4 times daily)
- Regular bowel program
- Assess AD symptoms and BP at every appointment
- Teach SCI patients significance of AD
  - Symptoms should prompt patients to empty bladder and bowel

Patient Resources

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Autonomic Dysreflexia Image 10
- Detrusor-Sphincter Dyssynergia
- Spinal Cord Injury

CODES
ICD9
- 337.3 Autonomic dysreflexia
- 596.89 Other specified disorders of bladder
- 599.0 Urinary tract infection, site not specified

ICD10
- G90.4 Autonomic dysreflexia
- N32.89 Other specified disorders of bladder
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS
- Most common triggers are from the genitourinary system such as bladder distention or instrumentation.
- AD occurs at and above level of T6.
- Chronic treatment with α-blockers may improve some symptoms of AD.
- Sphincterotomy or sphincter stent prosthesis allows reflex voiding with low-pressure bladder emptying into a condom catheter.
Epidemiology
Incidence (1)
- 0.3–0.5 episodes of bacteriuria per person per year among asymptomatic females aged 18–45
- Neonates: 1/105 (1–2 cases/100000 births)
- School age: Males: 0.04–0.2%; females: 0.7–2.7%
- Adult (involuted): Males <1%; females 4–6%
- Older adults: Males 11–13%; females 6–33%
- Almost 100% prevalence of bacteriuria in individuals with long-term, indwelling catheters

Prevalence
- Pregnancy: 2–7% of all pregnant females (2)
- Elderly: 20% of females, 10% of males (1)
- Pregnancy: 2–7% of all pregnant females (2)

Risk Factors
- Age, diabetes mellitus, sexual intercourse, use of diaphragm or spermaticide, delayed postpartum evacuation, history of recent infection, immunosuppression, long-term indwelling catheters, pregnancy, neurologic disorders, foreign bodies, stones, obstructive uropathy, telescopel reflux

Genetics
- Certain populations may be more susceptible to bacteriuria and recurrent UTI due to distinct molecular defects causing impaired host responses.
- Certain bacteria are more efficient at adhering to mucosal cells than others due to fimbria.
- Certain bacteria may be more efficient at adhering to mucosal cells than others due to fimbria.
- Cystitis prone: Certain patients are more prone to bacteriuria (transitional cell bacterial receptor sites).
- Cystitis: Clinical syndrome of dysuria, frequency, urgency occasionally with suprapubic pain.

Pathophysiology
- Urinary tract is normally sterile.
- Bacteriuria can also invade the urinary tract hematogenously or through direct transfer after instrumentation.
- Bacteriuria usually ascends up the urinary tract from the colonizing flora of the gut, vagina, or distal urethra.

Diagnosis
- History of childhood fevers: May imply UTIs and associated congenital abnormalities
- Problems with toilet training, urgency, incontinence
- U/S family history: Mothers, daughters, sisters
- History of a risk factor for bacteriuria

Physical Exam
- Suprapubic tenderness: Pyelonephritis
- Fever: Usually with upper tract infection
- Problems with toilet training, urgency, incontinence
- Children may have abdominal discomfort, tenderness, or distention

Diagnostic Tests & Interpretation
- Urine dipstick: Best for screening:
  - Leukocyte esterase test: 70–80% sensitivity for UTI
  - Pregnancy test: Can be used to differentiate infection from pregnancy

Microscopy:
- Rapid in-office test: 80% accurate, usually fresh sample
- Contains: Leukocytes, bacteria, erythrocytes,casts

Associated Conditions
- Diabetes mellitus, pregnancy, immunosuppression, structural urinary tract abnormalities, indwelling catheters

General Prevention
- Screening and treatment of asymptomatic bacteriuria in at-risk populations such as pregnant patients or prior to urologic intervention can prevent subsequent morbidity of 10%.
- Screening of asymptomatic spinal cord injury patients or those with indwelling Foley catheter is not recommended.

Bacteriuria and pyuria from an incompletely treated UTI may be avoided with the appropriate use of antibiotic class with sufficient duration; patient compliance should be encouraged.
DIFFERENTIAL DIAGNOSIS

- **Cystitis**: Pyuria, positive culture, abrupt onset
- **Unthritis**: Pyuria, negative urine culture, gradual onset
- **Vaginitis**: No pyuria, vaginal discharge, pruritus
- **Pyelonephritis**
- **Nephrolithiasis causes**: as in sterile pyuria
- **Contamination with vaginal/vulvar flora**

Diagnostic Procedures/Surgery

- **Localization of bacteria**: Segmented urine, ureteral catheterization
- **Immunologic antibody studies**

TREATMENT

**GENERAL MEASURES**

- **Obtain urine culture**: Indwelling catheters should be used as infrequently as possible
- **In patients with indwelling catheter**: urine specimen for culture should be obtained at the time catheter is changed under sterile conditions

**MEDICATION**

- **Asymptomatic bacteriuria is treated as a UTI in childhood, prior to urologic surgery, and in pregnancy**

**ADDITIONAL TREATMENT**

- **Radiation Therapy**

**ONGOING CARE**

- **Follow-up**: Repeat exam 2 wk posttreatment, not necessary in young women who are asymptomatic after therapy

**COMPLICATIONS**

- **Microscopic pyelitis and culture**
- **Periodic office visits to verify sterile urine**

**REFERENCE**

**ADDITIONAL READING**

BALANITIS AND BALANOPOSTHITIS
H. Henry Lai, MD, FACS
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION
- Balanitis: Inflammation of the glans penis.
- Balanoposthitis: Inflammation of the foreskin and glans penis (affects uncircumcised men).

EPIDEMIOLOGY

Incidence
- Can occur at any age.
- No incidence studies of balanoposthitis have been reported in US.
- 1.5% of uncircumcised boys ages 0–15 were affected in a Japanese cohort.

Prevalence
- Common, the exact prevalence is unknown.
- Balanitis affects 11% of adult men and 3% of boys seen in urology clinics.

RISK FACTORS
- Presence of a foreskin (uncircumcised)
- Tight foreskin (phimosis)
- Poor genital hygiene
- Intertrigo (see below)
- Sexual contact (with or without infection)
- Poorly controlled diabetes mellitus
- Immunocompromised host
- Coexisting penile cancer

GENETICS
- N/A

PATHOPHYSIOLOGY

- The pathophysiology is usually different in young boys compared to adult men:
  - Boys: From bacterial invasion of tissue
  - Men: Combination of poor genital hygiene, intertrigo, irritant dermatitis, maceration injury, and bacterial, or candidal overgrowth
- Candida is the most common infectious cause
- Intertrigo refers to a condition in which damp, moist body areas are predisposed to inflammation:
  - Involves genitals, inner thighs, underbelly
  - Risk factors: Grossly overweight, diabetes, bed rest, diaper use, poor personal hygiene

ASSOCIATED CONDITIONS
- Diabetes mellitus

GENERAL PREVENTION
- Maintain good genital hygiene
- Retraction of foreskin to clean the glans
- Keep the glans and foreskin dry
- Circumcision
- Safe sexual contact
- Manage risk factors (eg, glycemic control)

DIAGNOSIS

HISTORY
- Symptoms may include: Pain, discharge, irritation, voiding symptom (dysuria, weak stream)
- Prior episodes and treatment
- Uncircumcised
- Foreskin retractability
- Genital hygiene habits
- Sexual contacts, sexually transmitted diseases
- Other genitourinary risk factors (eg, diabetes)

PHYSICAL EXAM
- Inspection (ulcers, mass, genital pus, edema)
- Palpation (tenderness, induration, mass)
- Inguinal lymph nodes should be nonpalpable

TREATMENT

GENERAL MEASURES
- Meticulous genital hygiene
- Keep the glans and foreskin clean and dry
- Expose the glans to air as often as possible
- Avoid excessive dampness in the genitals
- Avoid soaps while inflammation is present
- Cleaning with soap and water routinely
- Manage risk factors (eg, glycemic control)

MEDICATION
- Treatment depends on the underlying cause (infectious vs. inflammatory) and organisms

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis
- Serology for syphilis
- Venereal disease research laboratory (VDRL) or rapid plasma reagin (RPR)
- Herpes simplex virus (HSV)–1 and –2
- Chlamydia trachomatis
- Neisseria gonorrhoeae
- Hepatitis A, B, and C
- Human immunodeficiency virus (HIV)
- Human T-lymphotropic virus type I (HTLV-I)
- Mycoplasma genitalium
- Ureaplasma urealyticum
- Trichomonas vaginalis
- Cytomegalovirus
- Enteroviruses
- Syphilis serology
- West Nile virus
- Human papillomavirus (HPV)

Imaging
- None

Diagnostic Procedures/Surgery
- Potassium hydroxide and Tzanck preparation for men
- Circumcision
- Potassium hydroxide smear evaluates for fungus
- Tzanck preparation for herpes virus

Pathologic Findings
- Biopsy is indicated for:
  - Balanitis that persists and in which the cause remains unclear warrants biopsy to rule out coexisting neoplasm or premalignant lesions
  - For definitive diagnosis of BXO

DIFFERENTIAL DIAGNOSIS
- Fixed drug eruption (allergic)
- Contact dermatitis
- Squamous cell carcinoma of the penis
- Carcinoma in situ of the penis
- Zoon (plasma cell) balanitis
- Psoriasis
- Reiter syndrome (Reactive arthritis/reactive arthritis triad) (with circinate balanitis)
- Human papilloma virus

42
**Balanitis and Balanoposthitis**

**First Line**
- **Candidal infection:** The most common cause of infectious balanitis.
  - Clotrimazole cream 1%
  - Miconazole cream 2%
  - Apply BID until symptoms resolve
  - Oral fluconazole if symptoms are severe
  - Nystatin cream if allergic to imidazole
  - Imidazole with hydrocortisone if inflammation

- **Anaerobic infection:**
  - Metronidazole 400 BID for 1 wk
  - Optimal dosage schedule is unknown
  - Alternatively, amoxicillin/clavulanic acid PO or clindamycin topically

- **Aerobic infection:**
  - Group A streptococci, Staphylococcus aureus, Gardnerella vaginalis are all reported cases of balanitis.
  - Treatment based on sensitivity of the culture (topical antibiotics, occasionally oral antibiotics)

- **BXO:**
  - Topical steroids (clobetasol propionate or betamethasone valerate) offers limited efficacy

- **Zoon (plasma cell) balanitis:**
  - Topical steroids with or without antibacterial cream

- **Circinate balanitis (Reiter syndrome):**
  - Hydrocortisone cream 1% apply BID
  - Treatment of associated infection

- **Irritant, allergic balanitis:**
  - Avoid exposure to irritants especially soaps
  - Emollients aqueous cream: Apply PRN and used as a soap substitute while inflammation is present
  - Hydrocortisone 1% apply QD or BID until symptoms resolve

**Second Line**
- **Radiation Therapy**
- **Additional Therapies**
- **Complementary & Alternative Therapies**

**Surgery/Other Procedures**
- Circumcision is reserved for recurrent balanitis, balanoposthitis, or phimosis that have failed conservative treatments.
- Occasionally dorsal slit may be performed.
- For BXO that does not respond to steroid.

**Surveillance**
- After acute episode and treatment is implemented, patients should be seen again to ensure resolution of symptoms and infection.
- Progression to cellulitis or gangrene may occur in diabetic patients with genital infection.
- Follow closely with genital dysplasia among those men with condyloma with a history of balanoposthitis than those with no such history.

**Patient Monitoring**
- Progression to cellulitis or gangrene may occur in diabetic patients with genital infection.
- Follow closely with genital dysplasia among those men with condyloma with a history of balanoposthitis than those with no such history.

**REFERENCES**

**CODES**
- **ICD9**
  - 605 Redundant prepuce and phimosis
  - 607.1 Balanoposthitis
  - 607.81 Balanitis xerotica obliterans

- **ICD10**
  - N47.1 Phimosis
  - N47.6 Balanoposthitis
  - N48.1 Balanitis

**Clinical/Surgical Pearls**
- Maintaining good genital hygiene is a key preventive strategy (keep the foreskin and glans clean and dry).
- Underlying risk factors should also be managed (eg, glycemic control) in diabetes.
- Treatment depends on the underlying cause (infectious vs. inflammatory) and organisms.
- Circumcision is reserved for recurrent balanitis, balanoposthitis, or phimosis that have failed conservative treatments.
- Balanitis that persists and if the cause remains unclear warrants biopsy to rule out coexisting neoplasm or premalignant lesions.
BCG SEPSIS/BCG-OSIS

John B. Eifler, MD
Michael S. Cookson, MD

BASICS
DESCRIPTION
- BCG sepsis: Potentially life-threatening event secondary to intravasation of intravesical BCG resulting in cardiovascular collapse and acute respiratory distress
- Possible etiologies include hypersensitivity reaction and bacterial sepsis
- "BCG-osis" is a term used to refer to disseminated disease in patients treated with BCG
  - The lungs and liver are typically involved
  - Patients are usually hemodynamically stable

EPIDEMIOLOGY
Incidence
- >95% of patients treated with BCG have no significant morbidity (1)
- 1 in 15,000 patients treated with intravesical BCG will develop BCG sepsis (2)
- 10 reported deaths due to BCG sepsis (3)

Prevalence
N/A

RISK FACTORS
- Inadequate delay after transurethral instrumentation (TURBT or bladder biopsy)
- Traumatic catheterization or gross hematuria at time of intravesical instillation

GENETICS
N/A

PATHOPHYSIOLOGY
- BCG is live attenuated Mycobacterium bovis
- Intravasation of BCG through damaged urothelium with subsequent systemic response
- Symptoms may be related to mycobacterial infection and/or hypersensitivity reaction

ASSOCIATED CONDITIONS
- Recent transurethral instrumentation
- Traumatic catheterization
- Concomitant UTI
- Age >70

ASSOCIATED MEASURES
- Consultation with infectious disease specialist is recommended for septic patients (2)
- If antitubercular therapy required, intravesical BCG should be discontinued (2)

LAB DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Mild/moderate symptoms
  - Urine culture
  - Severe symptoms (Septic, severe cystitis symptoms >48 hr)
    - Urine, blood cultures
    - Liver function tests to assess for hepatitis
    - CXR to assess for pneumonitis
    - Acid-fast testing of urine
    - Consider PCR testing for mycobacterial DNA if disseminated BCG suspected
- Coagulation studies: PT/PTT/ fibrinogen if DIC suspected

Imaging
- See “Lab

Pathologic Findings
- Noncaseating granulomas
  - May be found in lung, liver, bone, prostate, kidney, epididymis

DIFFERENTIAL DIAGNOSIS
- Post-BCG bacterial cystitis
- BCG cystitis (cytokine release without intravasation of BCG)
- Gram-negative sepsis

TREATMENT
GENERAL MEASURES
- Consultation with infectious disease specialist is recommended for septic patients (2)
- If antitubercular therapy required, intravesical BCG should be discontinued (2)

MEDICATION
First Line
- Mild/moderate symptoms including low-grade fevers
  - Fluoroquinolone
    - Such as levofloxacin 500 mg
    - Helpful for bacterial cystitis and has mild antitubercular activity
- Neutropenic
  - SUCH AS Levofloxacin 500 mg
- Such as levofloxacin 500 mg

- 995.39 Infection following other infusion, injection, transfusion, or vaccination

**ICD10**

- A41.89 Other specified sepsis
- T80.29KA Infct fol oth infusion, transfuse and therapeutic inject, iv

**CLINICAL/SURGICAL PEARLS**

- Patients undergoing intravesical BCG therapy who have traumatic catheterization or gross hematuria should delay therapy until symptoms resolve.
- Patients with high fever (>38.5°C/101.3°F) or severe cystitis symptoms lasting >48 hr should be hospitalized and undergo additional testing.
ASSOCIATED CONDITIONS
Pathophysiology
• May result from primary detrusor muscle failure (myogenic causes) and/or neurologic cause (eg, from lower motor neuron lesions, injury to spinal cord, multiple sclerosis).
• Patients often attempt to void by valsalva.
• Success of emptying depends on resistance of smooth and striated sphincter mechanisms.
• Continence depends on sphincter competence.

ASSOCIATED CONDITIONS
• Cause acute syndrome
• Diabetes mellitus
• Fowler syndrome (“nonneurogenic, neurogenic bladder”)
• Intervertebral disc diseases
• Longstanding bladder outlet obstruction with detrusor decompensation (myogenic failure)
• Lumbar sacral spinal surgery

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Blood: Creatinine to assess renal function.
• Urine: Urinalysis to assess renal infection.

Imaging
• Renal and bladder ultrasound (to assess renal stones, hydronephrosis).
BLADDER AREFLEXIA (DETROUSOR AREFLEXIA)

SURGERY/OTHER PROCEDURES
- Sacral neuromodulation (InterStim) in selected patients who do not have contraindications.
  - Effective in restoring voiding in patients with Fowler syndrome (1)
  - May be selectively considered in patients with nonobstructive urinary retention (2)
- Bladder augmentation may be considered in patients with poor detrusor compliance, and high detrusor leak point pressure and storage pressure.

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

ONGOING CARE
PROGNOSIS
- Most cases are irreversible, except the few circumstances described in “Differential Diagnosis”
- However, with proper urologic management, secondary complications may be minimized.

COMPICATIONS
- Bladder neoplasm from indwelling catheter
- Hydrophrosis and hydronephrosis
- Recurrent urinary tract infections
- Renal and bladder stones
- Renal insufficiency, failure, and dialysis
- Urethral erosion from chronic Foley catheter
- Urinary incontinence
- Urosepsis and death

FOLLOW-UP
Patient Monitoring
- Patients with poor detrusor compliance need periodic urodynamics studies, upper tract imaging, and urinary lab work to minimize complications.
- Patients who refuse to catheterize should be monitored closely.
- Patients with chronic indwelling catheter should undergo uroscopy periodically due to the increased risk of bladder neoplasm.

Patient Resources
- N/A

- Bladder Areflexia (Detrusor Areflexia) Image
- Neurogenic Bladder, General Considerations
- Sacral Neuromodulation
- Spinal Cord Injury, Urologic Considerations
- Urodynamics, Indications, and Normal Values

CODES
ICD9
- 596.55 Detrusor sphincter dysynergia
- 788.39 Other specified retention of urine
- 798.38 Overflow incontinence

ICD10
- R33.8 Other retention of urine
- N36.44 Muscular disorders of urethra
- N39.490 Overflow incontinence

CLINICAL/SURGICAL PEARLS
- Detrusor areflexia requires urodynamics for diagnosis.
- Urodynamics can distinguish detrusor areflexia from bladder outlet obstruction.
- Intermittent catheterization is preferred over chronic indwelling catheters.
- Sacral neuromodulation (InterStim) may be selectively considered in patients with nonobstructive urinary retention or Fowler syndrome.
- Patients with chronic indwelling catheter should undergo uroscopy and urine cytology periodically due to the increased risk of bladder neoplasm.
BLADDER CALCULI (VESICAL CALCULI)

Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

DESCRIPTION
Bladder calculi (also called bladder stones) are calcified material that are present in the bladder.
- It can originate primarily in the bladder.
- It can be a secondary renal stone that has formed in the kidney and passed into the bladder.
- Often associated with bladder outlet obstruction in the US.
- Historically the removal of bladder calculi was performed via an incision in the perineum with the patient in a supine position and the hips elevated (the origin of the term “lithotomy position”).

Epidemiology
Incidence
- The incidence of bladder calculus in the Western world has significantly dropped as a result of improved diet, nutrition, and infection control.
- Bladder calculi are endemic in Thailand, Burma, Indonesia, Middle East, and North Africa.
- Mostly in middle age men.
- In catheterized patients: The incidence of developing bladder calculus is 25% in 5 yr.
- The incidence in children has declined significantly in the developing countries; they are common in boys younger than 11 yr.
- Vaginal prolapse and urothelial surgery are common causes in women.

Prevalence
- Bladder calculus constitute 10–15% of the stone burden in adult and 15–30% in children.
- Data on the world-wide incidence are not available.

Risk Factors
- Urinary stasis
  - Bladder outlet obstruction
  - Benign prostatic hyperplasia
  - Urethral stricture
- Neurogenic bladder
- Foreign body such as urethral catheter and ureteric stent that act as nucleus for stone formation
- Urinary tract infection
- Urinary diversion and bladder substitution
  - Secondary to foreign body, infection, and systemic ailments
- Rarely patients may place foreign bodies in bladder that become calcified.

Genetics
N/A

PATHOPHYSIOLOGY
Bladder calculi are primarily formed in the bladder, rarely can be a secondary renal stone that has formed in the kidney and passed into the bladder.
- Foreign bodies, retained catheter bulbous fragments
- Patients with chronic intermittent catheterization may force pubic hair into the bladder that can become calcified over time.
- Stone analysis frequently reveals uric acid stone in 50% of the cases.
- Other constituents are ammonium urate, calcium oxalate, and calcium phosphate.
- In infected urine, struvite stones are the most common.
- In patients with spinal cord injury (SCI), bladder stones are often composed of struvite or calcium phosphate.
- In endemic areas, low phosphate diet results in increased ammonium excretion in the urine.
- Low intake of animal protein contributes to high urinary oxalate and low urinary citrate levels with increased risk of stone formation.
- Solitary stone are present in 75% of cases.

Associated Conditions
- Foreign bodies in the bladder
- Intermittent catheterization
- Low phosphate diet
- Urinary stasis (prostatic hyperplasia, stricture, congenital abnormalities [ureterocele], diverticulum, cystocele)
- Urinary tract infection

GENERAL PREVENTION
- Adequate hydration
- Treatment of bladder outlet obstruction
- Prevention of urinary tract infection
- Prevention of uricosuric as appropriate
  - Allopurinol for uric acid stones
- Reduce oxalate intake
- Increase urinary citrate
- Low sodium low protein diet

DIAGNOSIS

HISTORY
- Patients with SCI, neurogenic bladder may be at increased risk.
- Bladder calculi may be asymptomatic and may be incidental finding on imaging (plain x-ray, renal ultrasound, CT, or flexible cystoscopy).
- Patients commonly presents with:
  - Suprapubic or perineal pain
  - Irritative urinary symptoms
  - Intermittent urinary stream
  - Hematuria, gross, and microscopic
  - Resistant urinary tract infection

PHYSICAL EXAM
- Examine the abdomen for palpable bladder or kidney.
- Examine the external genitalia for any abnormalities (ureterocele) that may contribute to outlet obstruction.
- Digital rectal exam to assess for BPH and prostate cancer.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine analysis: Hematuria, leukocytes, and crystalluria may be present
- Urine culture and sensitivity in case of suspected infection
- Urine cytology in the presence of calculi is nonspecific
- Serum creatinine
- Stone analysis should be considered when removed

Imaging
- Calculi stones can be visible on plain x-ray (KUB)
- Stones may be densely radiopaque
- Occasionally laminations may be visible on plain x-ray
- Uric acid and ammonium urate stones are radiolucent but will be seen on ultrasounds or CT scans.
- Bladder calculi may not be visible on MRI
- CT without contrast is highly sensitive and specific to detect calculi, however it is rarely used to diagnose bladder stones.
BLADDER CALCULI (VESICAL CALCULI)

Diagnostic Procedures/Surgery
- Cystoscopy to visualize the stone and guide subsequent removal of the stone.
- Allows evaluation of bladder outlet obstruction or other abnormality such as bladder diverticulum.

Pathologic Findings
- Acute and chronic inflammation.
- Squamous metaplasia and squamous cell carcinoma can result from chronic vesical calculus irritation.

Differential Diagnosis
- Bladder diverticulum.
- Bladder malignancy with or without calcification.
- Other bladder malignancies.
- Chronic pelvic pain syndrome.
- Fungal bezoar or blood clot.
- Intestinal cysts.
- Lower urinary tract symptoms due to bladder outlet obstruction.
- Oversecreting bladder.
- Urinary tract infection.
- Urinary unbladder.
- Vital unbladder stones can cause significant vesical irritation.

Treatment

General Measures
- Surgical removal is the mainstay treatment.
- Determining and correcting the cause (i.e., bladder outlet obstruction) should be a priority.

Medication
First Line
- Medical therapy is used to treat associated urinary tract infection.
- Cystoscopy/cystolitholapaxy using stone fragmenting forceps.
- Electrohydraulic, ultrasonic, laser, and pneumatic lithotrites are used for larger or harder stones.
- Large stones can be removed through small abdominal incision (open cystolitholapaxy).
- Cystolitholapaxy can be safely combined with procedures such as TURP or TUIP for bladder outlet obstruction.

Additional Treatment
- Radiation Therapy
- Additional Therapies
  - ESWL has a limited role in treating bladder calculi.
  - Bladder outlet procedure may be necessary if urinary stones are causing vesical calculi to improve bladder emptying.
  - Consideration to repair of bladder diverticulum or other anatomic abnormality if contributory.

Complementary & Alternative Therapies
- N/A

Ongoing Care

Prognosis
- Excellent with complete stone removal and associated bladder outlet obstruction are treated.
- Metabolic stone evaluation may be considered if appropriate (i.e., multiple upper tract calculi, recurrent bladder calculus, etc.).

Complications
- Recurrent urinary tract infection.
- Squamous metaplasia.
- Chronic irritation may result in secondary malignancy (i.e., squamous cell carcinoma).

Follow-Up
- Patient Monitoring
  - Urine analysis.
  - Flowmetry and postvoid residual.
  - Urinalysis for crystals.
- Renal ultrasonographic scan to screen for upper tract stone.

Patient Resources
- Published Health: Bladder Stones http://www.ncbi.nlm.nih.gov/pubmed/PMID002254

References

Additional Reading

See Also (Topic, Algorithm, Media)
- Bladder Calculus (Vesical Calculus) Image 42
- Bladder Diverticulum
- Bladder Filling Defect
- Bladder Wall Calcification, Differential Diagnosis
- Fungal Infections, Genitourinary
- Unbladder, Adult, General Considerations

Codes
- ICD9
  - 594.0 Calculus in diverticulum of bladder
  - 594.1 Other calculus in bladder
- ICD10
  - N21.0 Calculus in bladder
  - N21.0 Bladder neck obstruction

Clinical/Surgical Pearls
- If an otherwise healthy person is found to have a bladder calculus, a complete evaluation is warranted to evaluate for causes such as urinary stones.
BLADDER CANCER, ADENOCARCINOMA

Matthew A. Young, MD
Sandip M. Prasad, MD, MPhil

BASICS

DESCRIPTION
- Adenocarcinoma of the bladder is an uncommon and frequently aggressive nonurothelial cancer.
- It is frequently muscle-invasive or metastatic at the time of diagnosis and therefore carries a poor prognosis.
- A common site is the urachus.

Epidemiology
- 0.3–0.5% of all primary bladder malignancies, making it the 3rd most common epithelial tumor of the bladder.
- Can arise from the urothelium or nonurothelial epithelium, or in association with ectopy of the bladder.
- Most common tumor arising in the bladder of ectopy patients, who have a 4% lifetime risk.
- A majority of nonurothelial, nonectopy-associated adenocarcinomas occur in men and are frequently associated with long-term inflammation or infection.
- Occurs more frequently in areas where Schistosoma is endemic.

Urachal cancer: <1% of primary bladder cancer; 1/10 of bladder adenocarcinomas

RISK FACTORS
In tissue-relevant studies, adenocarcinoma can be produced from bladder urothelium under the appropriate hormonal and neuroendocrine stimuli.

Genetics
- Associated with gain of function in regions 20q and 8p, or loss of function in regions 5q and 8p (1).

PATHOPHYSIOLOGY
Classification: 3 groups, related to site of tumor origin (2,3)
- Primary adenocarcinoma of bladder.
- Urethral adenocarcinoma.
- Extravesical adenocarcinoma (metastasis).
- Primary vesical adenocarcinoma: Can occur anywhere in the bladder, but the dome and the trigone of the bladder are common.
- Most common type of cancer in bladder exstrophy.
- All histologic variants of enteric carcinoma may occur in the bladder.
- Papillary or solid, most are mucin-producing.
- Most are poorly differentiated and invade at the time of diagnosis.

Urachal adenocarcinoma: For classification as a urachal carcinoma, there must be:
- Presence of a urachal remnant.
- Clear demarcation between the tumor and adjacent bladder mucosa.
- Predominant invasion of the muscularis propria or deeper structures of the bladder or extension to the space of Retzius, anterior abdominal wall, or umbilicus.
- Possible production of mucoid drainage from the umbilicus.

M.D. Anderson Cancer Center Diagnostic Criteria for Urachal Carcinoma:
- Location in bladder dome or elsewhere in the midline of the bladder.
- Sharp demarcation between tumor and normal surface epithelium.
- Supportive criteria:
  - Eutopic-type histology.
  - Absence of urothelial dysplasia.
  - Absence of cystitis cystica or cystitis glandularis transforming to the tumor.
  - Absence of primary adenocarcinoma of another organ.

- May produce stippled calcifications on plain films.
- Prognosis is worse for urachal carcinoma than for primary adenocarcinomas of the bladder.
- Urachal carcinoma demonstrates more extensive infiltration of the bladder wall, and for this reason, radical cystectomy is preferred over partial cystectomy, although the latter is still an option.
- Urachal carcinomas are not always adenocarcinomas: Most common type.
- Others include transitional cell carcinoma, squamous cell carcinoma, and rarely sarcoma.

Metastatic lesions are very rare:
- Adenocarcinomas from the colon, stomach, breast, ovary, endometrium, and prostate can metastasize to the bladder.
- Local invasion of a colonic primary tumor is more common than metastasis.
- Bladder adenocarcinoma is histologically indistinguishable from adenocarcinoma of the colon.

Sheldon Staging System for Urachal Carcinoma:
- Stage I: No invasion beyond the urachal mucosa.
- Stage II: Invasion confined to the urachus.
- Stage III: Local extension into the bladder (B3A).
- Stage IV: A - Abdominal wall (B3B).
- Stage IV: B - Peritoneum (B3C).
- Stage IV: C - Viscera other than bladder (B3D).
- Stage IV: D - Adenocarcinoma of the colon.

ASSOCIATED CONDITIONS
- Bladder exstrophy.
- Schistosomiasis.

GENERAL PREVENTION
Elimination of factors leading to chronic bladder inflammation.

DIAGNOSIS

HISTORY
- Hematuria, mucopurulent urethral discharge.
- Usually painless.
- Intermittent voiding symptoms (frequency, urgency, dysuria).
- Foreign body Schistosomiasis.
- Weight loss, flank pain, umbilical discharge (rare).
- Chronic infection.
- History of exstrophy or other bladder pathology.
- History of colon cancer or other malignancy, risk of metastatic lesion.

PHYSICAL EXAM
- Pelvic mass by bimanual rectal exam.
- Bloody or mucoid-umbilical discharge or umbilical mass.
- Digital rectal exam: Presence of blood in stool.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine studies: Urinalysis, culture and sensitivity, urinocytology.
- Serum electrolytes: BUN/Creatinine, liver function tests.
- Carcinoembryonic antigen (CEA), CA125, and CA19-9 may be elevated in 40–60% of patients presenting with peritoneal carcinomatosis.

Imaging
- Urachal cancers may show stippled calcifications on plain x-ray films.
- 60% of bladder tumors are detected with IVU, which has been largely replaced with the CT scan.
- CT scan: Imaging method of choice for staging of bladder tumors; useful for detecting presence of pelvic lymphadenopathy and extravesical tumor extension.
- Sensitivity: 64–94%, specificity: 62–100%.
- Other investigations: CTA (staging), bone scan (imaging if bone pain is present), GI endoscopy, and breast exam (to exclude primary tumor) if clinically indicated.

Diagnositc Procedures/Surgery
- Diagnostic cystoscopy and biopsy:
  - Essential for definitive diagnosis.
  - Bloody efflux from ureteral orifices suspicious for upper tract pathology.

Pathologic Findings
- All histologic variants of enteric carcinoma may occur in the bladder.
- Adenocarcinomas can have glandular, mucinous, or signet ring patterns.
- Most produce mucin.
- Primary adenocarcinomas of the bladder are associated with cystitis glandularis and is thought to arise from glandular metaplasia of the urothelium.
- These tumors can be papillary or solid.
- Signet ring tumors produce limk plastic of the bladder.
- They are aggressive and radical surgical excision should be considered.
**Differential Diagnosis**
- Metastasis from ovary, prostate, or other adenocarcinoma
- Benign or malignant urothelial tumors

**Treatment**

**General Measures**
- Site of origin and tumor behavior are factors important in determining treatment
- Adenocarcinoma of the bladder is generally unresponsive to radiation and chemotherapy.
  - Radical cystectomy is treatment of choice.
  - Excision of the urachus and umbilicus is usually required if a urachal primary is suspected
- Adjunct chemotherapy or radiotherapy may be used, but surgery remains the most consistently effective treatment ([4,6])

**Medication**

**First Line**
- Generally unresponsive to radiation and cystotoxic chemotherapy ([7])
- Some response to standard regimens such as combination methotrexate, vinblastine, adriamycin, cisplatin (MVAC)
- Recently, 5-FU and cisplatin-based chemotherapy have demonstrated a modest response rate
- A clinical trial at M.D. Anderson using gemcitabine, 5-FU, leucovorin, and cisplatin (Gem-FLP) reported a clinical response rate in 30–40% of patients
- Currently there is no role for neoadjuvant chemotherapy for clinically node-negative resectable disease

**Second Line**
- 5-FU

**Surgery/Other Procedures**
- Radical cystectomy with pelvic lymph node dissection remains the gold standard
- Adjunct chemotherapy or radiotherapy has not improved survival significantly
- Partial cystectomy (with bladder mucosal sampling) with an en bloc removal of the urachus and umbilicus is an option for low-volume, low-stage urachal carcinoma

**Additional Treatment**

**Radiation Therapy**
- Urachal adenocarcinomas are radio resistant

**Additional Therapies**
- N/A
- Complementary & Alternative Therapies
- N/A

**Ongoing Care**

**Prognosis**
- Signet cell variant has a 50% mortality at 1 yr
- Urachal adenocarcinoma: Overall 11–15% 5-yr survival, but early-stage disease may have up to 90% 5-yr survival
- Nonurachal adenocarcinoma: 27–61% 5-yr survival
- Recurrence risk for urachal carcinoma
  - Positive margin
  - Urachal cysts or scarring are associated with a higher risk of relapse
  - Tumor involving the parietal surfaces or the abdominal wall
  - Occult length node metastases

**Complications**
- Urinary obstruction from local spread of tumor
- Metastasis to pelvic lymph nodes, liver, lung, mediastinum, and bone
- Surgical complications: Bleeding, infection, rectal injury

**Follow-Up**

**Patient Monitoring**
- Abdominal imaging (CT)
- Metastatic workup if suspected

BLADDER CANCER, GENERAL
Matthew A. Young, MD
Sandip M. Prasad, MD, MPhil

PATHOPHYSIOLOGY

- 70% of tumors present as nonmuscle-invasive lesions
- 20% of these are Ta, 20% T1, 10% CIS
- Risk of recurrence
  - CIS: 50–90%
  - Ta low grade: 50–70%
  - Ta high grade: 60%
  - T1 high grade: 70–80%
  - Risk of recurrence in upper tracts 2–4%
- Risk of progression
  - CIS: >50%
  - Ta low grade: 5–10%
  - Ta high grade: 15–40%
  - T1 high grade: 30–50%
  - Most important prognostic factor is grade
  - Concurrent upper tract UCC in patients with bladder cancer is 2–4%

ASSOCIATED CONDITIONS

- Other smoking related illnesses (COPD)
- Adenocarcinoma, squamous cell
- Small-cell carcinoma
- Bone scan is recommended only in patients with bone pain, elevated calcium, or elevated alkaline phosphatase

DIAGNOSIS

HISTORY

- Gross painless hematuria is the most common presenting symptom
- Hematuria and flank tenderness (sensitivity 77%, specificity 98%)
- Urinalysis for hematuria screening
- High-fat diet has been associated with increased risk of bladder cancer

PHYSICAL EXAM

- Assess all urinary tract structures
- Painful, gross hematuria and may reveal palpable mass in bladder

DIAGNOSTIC TESTS & INTERPRETATION Lab

- Urinalysis with microscopy: RBCs
- Urine cytology
  - High specificity (96%), more sensitive for high-grade tumors (10%)
  - Other urinary markers
    - FISH (evaluate aneuploidy for chromosomes 3, 7, 17 and Bcl-2)
    - Sensitivity 77%, specificity 98%
    - MIB-1 (marker of aneuploid cells)
  - Sensitivity 56%, specificity 85%
- Renal function tests (BUN, Creatinine)
  - May indicate renal impairment secondary to ureteral obstruction
- Liver function tests
  - May be abnormal due to metastasis

Imaging

- CT abdomen/pelvis
  - Can detect lymphadenopathy and other intra-abdominal disease
  - Presence of hydronephrosis is suggestive of muscle invasive disease
- CT angiography has replaced IV as standard for evaluating upper tracts
- MRI may be useful for local staging
- Chest x-ray (CXR): Metastasis with muscle invasion
- Bone scan is recommended only in patients with bone pain, elevated calcium, or elevated alkaline phosphatase

Diagnostic Procedure/Surgery

- Cytoscopy is the most accurate initial diagnostic procedure
- Can be done in office with local anestheisia

Pathologic Findings

- Transitional cell carcinoma (urothelial carcinoma), 90%
- Squamous cell carcinoma, 3–7%
- Adenocarcinomas, <2%
- Small-cell carcinoma (lymphoma, carcinoma, lymphoblastoma, uncertain)
- Renal/gonadal and female reproductive system
- Bone pain, elevated calcium, or elevated alkaline phosphatase
- Blood in stool
- Urine in stool
- Hematuria: 85% have hematuria
- Congenital/familial causes: Cystinuria, hypercalciuria
- Renal/renal cell carcinoma
- Calcium stones (90% of adults with stones, gross hematuria and ~10% with painless microscopic hematuria have a malignancy), benign tumors, endometriosis
- Metabolic causes: (10% most common cause of hematuria in adults), other infections (diabetes mellitus, TB, syphilis, radiation cystitis)
- Rapidly progressive glomerulonephritis
- Schistosomiasis
- Urorheumatism
- Urothelial, 85% have hematuria
- Congenital/familial causes: Cystinuria, hypercalciuria
- Metabolic causes: (90% most common cause of hematuria in adults), other infections (diabetes mellitus, TB, syphilis, radiation cystitis)
- Renal/renal cell carcinoma
- Calcium stones (90% of adults with stones, gross hematuria and ~10% with painless microscopic hematuria have a malignancy), benign tumors, endometriosis
- Metabolic causes: (10% most common cause of hematuria in adults), other infections (diabetes mellitus, TB, syphilis, radiation cystitis)
- Renal/renal cell carcinoma

CODES

ICD 188.8 Malignant neoplasm of trigone of urinary bladder
188.8 Malignant neoplasm of other specified sites of bladder
186.9 Malignant neoplasm of bladder, part unspecified

ICD10
• C67.8 Malignant neoplasm of trigone of urinary bladder
• C67.8 Malignant neoplasm of other specified sites of bladder
• C67.8 Malignant neoplasm of bladder, part unspecified

CLINICAL/SURGICAL PEARLS
70% of bladder cancers present as nonmuscle-invasive lesions.
RISK FACTORS
- Tobacco smoking history (most common risk factor)
  - Overall 2.8x higher incidence in smokers
  - Risk increases with number of pack-years
  - 6x risk for 62 pack-year history
- Latency often >20 yr from time of exposure
- Quitting decreases risk
  - >15 yr after quitting, relative risk 1.1
- Occupational exposure
  - Organic chemicals, especially aromatic (Vin anilines)
  - Naphthoquinones, benzidine, aniline dyes, 4-aminoazobenzene
  - High-risk occupations: Petroleum/rubber/leather/paint/textile workers, hairdressers, truck drivers, aluminum electroplaters
- Asbestos contamination of drinking water
  - Latency may be 40 yr
- Chemoexposure with cyclophosphamide (Cytoxan)
- Helicobacter pylori
  - 4x increased risk after RT for cervical cancer
  - 1.5x risk after RT for prostate cancer
- Chronic hepatitis
  - SCC
- Indwelling catheters, chronic bladder catheter
- Cysts due to Schistosoma hematobium

PATHOPHYSIOLOGY
- Inciting genetic event
  - Low grade (LG). Deletion of part of chr 9 (RB gene) and/or mutation in FGFR-3
  - High grade (HG). Numerous mutations (particularly TP53), aneuploidy of chr 7, 9, 17
- NMIBC comprises ∼75% of bladder cancer
- Recurrence rate: ∼40% for LG, >80% for HG
- Most recurrences within 1st 6 mo after TURBT, but may occur after many years
- May also recur in upper tracts or prostate urethra
- Progression influenced by stage and grade
  - Stage Ta, LG: 5–10%; HG: 15–40% at 5 yr
  - Stage T1, HG 30–50% at 5 yr
- May also recur in upper tracts or prostate urethra
  - Stage T1, HG 30–50% at 5 yr
  - High-grade (HG) 10–25% for HG Ta, 33% for HG T1 (T1)
- Other risk factors for progression
  - Architecture: Non-papillary/broad based
  - Multifocality = >50%
  - Size >5 cm
  - Lymphovascular invasion
  - Focal lesions in FTA, RB, and PFEN predict poor prognosis

ASSOCIATED CONDITIONS
- See “Risk Factors”

GENERAL PREVENTION
- Smoking cessation
- Avoidance of occupational exposure
- Hydration long-term beneficial

DIAGNOSIS

HISTORY
- Most common in men >50; Males = females due to smoking prevalence
- 1st occurrence: 85% present with either gross or microscopic hematuria. Painless gross hematuria is hallmark of bladder CA
- Initial symptoms (eg, dysuria, urgency, frequency) occasionally due to bladder CA, especially CIS
- Microscopic hematuria typically present if due to cancer
- Smoking history:
  - Record total pack-years, current packs/day, and years since quitting if applicable
- Occupational risk factors

PHYSICAL EXAM
- Usually unrewarding for NMIBC

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - CBC including dipstick and micro evaluation for RBCs
  - Urine cytology: High specificity but low sensitivity.
  - Other urinary tests: urine cytology, BTA-Stat, NMP22, UrineVysion FISH: Low sensitivity and specificity for LG disease. Not generally recommended for routine workup of microscopic hematuria but may be considered for high-risk patients (see “Additional Reading”)
- Imaging:
  - CT urogram: Evaluate renal parenchyma, renal collecting system, and ureters
  - CT urogram (3-phase CT abdomen/pelvis with IV contrast): Study of choice for evaluation of gross/microscopic hematuria
  - If patient cannot receive IV contrast, consider MRI + RPR (intravenous pyelogram)

Diagnosing Procedure/Surgery
- Bladder CA typically detected on cystoscopy
- Cystoscopy indicated for gross hematuria and most cases of microscopic hematuria (see chapter “Hematuria, gross and microscopic, adult”)
- In-office, under local anesthesia, at time of initial presentation. It may be combined with biopsy
- TURBT under general or spinal anesthesia is definitive
- Retrograde pyelography may be used for equivocal CT urogram or when CT urogram/MRI contraindicated to exclude concomitant upper tract lesions in patients with hematuria or positive cystoscopy

Pathologic Findings
- Urine Cytology
  - Precursors to CIS/Unifocal cancer
- Papillosa
  - Papillary lesion with low recurrence risk (0–4%) or progression risk (1%)
- Papillary Urothelial Neoplasm of Low Malignant Potential (PUNLMP)
  - Papillary growth, minimal cytologic atypia
  - Recurrence 35%, progression 4%
- CIS: See chapter “Bladder Cancer, urothelial, superficial, carcinoma in situ (CIS)”
- Bladder cancer: Confined to either urothelium (stage T1) or invasion of lamina propria (stage T1) and may be LG or HG

DIFFERENTIAL DIAGNOSIS
See Section 1 “Bladder cancer, general” for complete differential diagnosis of hematuria and bladder filling defects

Bladder cancer is a malignant neoplasm usually arising from the lining of the bladder (urothelium).
- A papillary tumor confined to the mucousa is classified as stage Ta according to the Tumor, Node, Metastasis (TNM) classification system.
- Tumors that have invaded the lamina propria are classified as stage T1.
- Ta and T1 tumors can be removed by transurethral resection (TUR), and are called NMIBC (non-muscle-invasive bladder cancer).
- Most common histology: urothelial carcinoma (previously called transitional cell carcinoma/TCC)
- ∼75% of bladder cancers are non-muscle-invasive at presentation.
- Challenging management: Due to recurrence and potential to progress to lethal disease
- Due to need for lifelong monitoring, highest cost per patient of any cancer
- Bladder cancer is a malignant neoplasm usually arising from the lining of the bladder (urothelium).
- Due to need for lifelong monitoring, highest cost per patient of any cancer
- Challenge management: Due to recurrence and potential to progress to lethal disease
- Most common histology: urothelial carcinoma (previously called transitional cell carcinoma/TCC)
- ∼75% of bladder cancers are non-muscle-invasive at presentation.
- Bladder cancer is a malignant neoplasm usually arising from the lining of the bladder (urothelium).
- Due to need for lifelong monitoring, highest cost per patient of any cancer
- Challenging management: Due to recurrence and potential to progress to lethal disease

- Bladder cancer is a malignant neoplasm usually arising from the lining of the bladder (urothelium).
- Due to need for lifelong monitoring, highest cost per patient of any cancer
- Challenge management: Due to recurrence and potential to progress to lethal disease
- Most common histology: urothelial carcinoma (previously called transitional cell carcinoma/TCC)
- ∼75% of bladder cancers are non-muscle-invasive at presentation.
ADDITIONAL TREATMENT
Radiation Therapy
No role in superficial disease

Additional Therapies
Adjunct intravesical chemotherapy/immunotherapy (as above)

Compensatory & Alternative Therapies
Mediastinal seed (high intake of fruit, vegetables, legumes) thought to lower risk of urethral cancer (5)

ONGOING CARE

PROGNOSIS

CLINICAL/SURGICAL PEARLS

Greatest risk factor for progression to MIBC is high-grade disease.
Administration of mitomycin C at the time of TURBT for low-grade NMIBC decreases risk of recurrence but not progression.
Though the majority of men with high-grade NMIBC respond to BCG, most will ultimately recur.

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)

ICD-10 C67.9 Malignant neoplasm of bladder, part unspecified

ICD-10 C67.9 Malignant neoplasm of bladder, unspecified

BLADDER CANCER, NON-MUSCLE-INVASIVE BLADDER CANCER (TA, T1) (NMIBC)

SURGERY/OTHER PROCEDURES

• Repeat TURBT indicated for T1 and HG. As many as 25–50% may harbor worse prognostic findings on 2nd TURBT.
• Bladder biopsies (random): Helpful if positive cytology with no obvious lesion.
• Laser electrofulguration useful for recurrent, small, LG, papillary tumors, may be performed under local anesthesia.
• Fluorescence “Blue Light” Cystoscopic. – Intravesical agents bind porphyrins in neoplastic tissue and fluoresces under Blue light.
• Improves detection of papillary tumors and CIS. – Decreases recurrence but not progression.
• Recommended by EAU guidelines.

Narrow band imaging (NBI) is an evolving endoscopic technology.

Radical cystectomy: Indicated in HG NMIBC. Narrow band imaging (NBI) is an evolving endoscopic technology.
BLADDER CANCER, SQUAMOUS CELL CARCINOMA

Daniel J. Canter, MD

PATHOPHYSIOLOGY (1)
- Schistosomiasis infection
- Transitional cell dedifferentiation
  - Transitional cells possess unique ability to
dedifferentiate into any cell type
- Chronic irritation of bladder mucosa due to a variety of
etiologies, especially SCCs
- Most common bladder sites are the lateral wall and
trigone

ASSOCIATED CONDITIONS
- Neurogenic bladder/SCIs
- Need for chronic indwelling Foley/CIC
- Smoking history
- Living and travel to areas endemic with
schistosomiasis

ASSOCIATED CONDITIONS
- Schistosomiasis infection
- Transitional cell carcinoma (TCC) can differentiate
into any histology
- Smoking
- Chronic bladder infection/irritation
  - Patients with SCIs
  - Chronic indwelling Foley catheter/CIC
  - Chronic infection
  - Bladder stones
  - Leukoplakia
  - Squamous metaplasia
- HPV infection
- Industrial exposures for workers involved in
the production of rubber, leather, textiles, and paint
(traditionally more associated with the development
of pure urothelial carcinoma)

Genetic
- Association with variations in inflammatory genes
- Epithelial growth factor receptor and p53
everexpression implicated as well as p16
abnormalities
- Keratin 10 and cavin-1 identified as potential
markers of differentiation from TCC to SCC

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis/culture
- Urinary cytology usually not reliable
- CBC
- Comprehensive metabolic panel, including (liver
function testing) LFTs, alkaline phosphatase, and
albumin

Imaging
- Cross-sectional imaging of the chest, abdomen, and
pelvis based on patient’s renal function (CT scan vs.
MRI)
- Bone scan if elevated calcium, alkaline phosphatase,
or unexplained pain

Diagnostic Procedures/Surgery
- Exam under anesthesia (USA) and transurethral
resection of bladder tumor (TURBT) of primary
tumor for histologic diagnosis and clinical staging
- Radical cystectomy with lymph node dissection and
primary diversion is considered for the treatment

Pathologic Findings
- Mixed urothelial and squamous carcinomas are
more common than pure SCCs
- The term SCC of the bladder is used only if tumor
is solely composed of squamous cell component,
with no urothelial carcinoma component
- Grading unreliable. Mostly considered a high-grade
neoplasm

Histologic findings
- Squamous metaplasia
- Keratinized islands
- Squamous pearls
- Interstitial bridges
- Histologic figures common

DIFFERENTIAL DIAGNOSIS
- Urothelial carcinoma of the bladder
- Squamous metaplasia
- Other histologic variant of bladder
(sarcomatoid, adenocarcinoma, etc.)
- Invasive cervical cancer: Often squamous cell

DIAGNOSIS
- History of living/travel to countries with endemic
schistosomiasis
- In general, in Western countries, patients who have
SCC of the bladder present in the same manner as
urothelial carcinoma of the bladder
- Hematuria
- Constitutional symptoms
- Flank/back pain due to ureteral obstruction
- History of chronic irritation to bladder mucosa

PHYSICAL EXAM
- Palpable mass on rectal/vaginal exam
- Gross hematuria

HISTORY
- History of living/travel to countries with endemic
schistosomiasis
- In general, in Western countries, patients who have
SCC of the bladder present in the same manner as
urothelial carcinoma of the bladder
- Hematuria
- Constitutional symptoms
- Flank/back pain due to ureteral obstruction
- History of chronic irritation to bladder mucosa

DESCRIPTION
- Squamous cell carcinoma (SCC) of the bladder is a
histologic variant of bladder cancer
- Most frequent histologic form of bladder cancer in
countries with endemic schistosomiasis
- SCC comprises 2–5% of all bladder
cancers—most common histologic variant in
Western countries

Epidemiology
Incidence
- 2–5% of bladder cancers in Western countries
- Originally reported that patients with spinal cord
injuries (SCIs) had an incidence of SCC of the
bladder of 2.3%—more recent data only suggests
0.39% incidence
- Approximately 75–80% of all bladder cancers are
SCCs in regions with endemic schistosomiasis

Prevalence
- Difficult to assess since so many of these patients will
ultimately die of bladder cancer

Risk Factors
- Schistosomiasis infection
- TransITIONAL cell carcinoma (TCC) can differentiate
into any histology
- Smoking
- Chronic bladder infection/irritation
  - Patients with SCIs
  - Chronic indwelling Foley catheter/CIC
  - Chronic infection
  - Bladder stones
  - Leukoplakia
  - Squamous metaplasia
- HPV infection
- Industrial exposures for workers involved in
the production of rubber, leather, textiles, and paint
(traditionally more associated with the development
of pure urothelial carcinoma)

Genetics
- Association with variations in inflammatory genes
- Epithelial growth factor receptor and p53
  neverexpression implicated as well as p16
  abnormalities
- Keratin 10 and cavin-1 identified as potential
  markers of differentiation from TCC to SCC
BLADDER CANCER, SQUAMOUS CELL CARCINOMA

TREATMENT

GENERAL MEASURES
• Treatment is related to stage
• In general, SCC of the bladder presents with locally advanced disease, and radical cystectomy with urinary diversion is an integral part of the treatment paradigm
• Although uncommon, noninvasive lesions can be treated with local resection and diligent surveillance

MEDICATION
First Line
• Systemic chemotherapies have been used with limited experience in treating SCC of the bladder
• Small series have reported positive responses to cisplatin-based therapies, similar to pure urothelial carcinoma
• At present, role for neoadjuvant/adjuvant chemotherapy is poorly defined

Second Line
N/A

SURGERY/OTHER PROCEDURES (2)
• After diagnosis is confirmed, radical cystectomy is 1st-line treatment
• Bladder-preserving therapies can be considered if tumor is nonmuscle invasive and completely resected, and patient is willing to commit to intensive surveillance protocol
• Limited experience with chemoradiotherapy as primary treatment modality

ADDITIONAL TREATMENT
Radiation Therapy
Can be used in adjunct setting for patients with positive surgical margins at time of surgery

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
• Related to pathologic stage (3)
• Evidence suggests that patients with SCC of the bladder tend to present with higher-stage (pT3/T4) disease at the time of radical cystectomy
• Overall survival has ranged from 4.8 to 50%
• 5-yr cancer-specific survival in contemporary series has ranged from 57 to 64%

COMPICATIONS
• Related to radical cystectomy and urinary diversion
  – Perioperative mortality approaches 2%
  – 40-50% of patients will experience a postoperative complication
  – Gastrointestinal complication is most common, e.g., ileus, small bowel obstruction

FOLLOW-UP
Patient Monitoring
• Related to tumor stage at the time of radical cystectomy
  – In general, patients are followed with history, physical exam, laboratory studies (CBC and comprehensive metabolic profile, including liver function tests) and cross-sectional imaging of chest, abdomen, and pelvis every 3–6 mo after surgery for the first 2 yr then semiannually for 2 yr then annually
  – Renal function needs to be followed annually as well

Patient Resources
Bladder Cancer Advocacy Network (www.bcan.org)

See Also (Topic, Algorithm, Media)
• Bladder Cancer, General
• Bladder Cancer, Squamous Cell Carcinoma Image
• Bladder Cancer, Urothelial, Muscle Invasive (Clinical and Pathologic T2/T3/T4) (MIBC)

CODES

ICD9
188.9 Malignant neoplasm of bladder, part unspecified

ICD10
C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS
• With the control of schistosomiasis in endemic regions, the rate of SCC is dropping relative to the diagnosis of urothelial carcinoma
• Radical cystectomy is the gold standard for muscle-invasive SCC of the bladder
BLADDER CANCER, UROTHELIAL, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)

Jean Hoffman-Censits, MD
Wm. Kevin Kelly, DO

GENERAL PREVENTION
• Smoking cessation
• Limit or modify chemical exposure
• Hydration may limit tumor exposure

DIAGNOSIS
• Many tumor recurrences are noted during routine radiographic surveillance, which is standard following radical cystectomy.
• Pain from bone metastasis, lymphatic progression in the retroperitoneum, bowel obstruction with carcinomatosis, and symptoms of visceral progression such as in the lungs and liver can be symptoms of metastatic bladder cancer.

PHYSICAL EXAM
• Most with early advanced or metastatic disease have no significant external exam findings.
• Palpable lymphadenopathy, hepatomegaly from liver involvement, as well as cachexia of malignancy can be noted.
• Low edema with venous thromboembolism is present (incidence 1-8%); higher incidence with platinum combination therapy.
• Poor nutrition and increased abdominal girth in setting of ascites and soft tissue intra-abdominal recurrence can contribute to edema.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Lab abnormalities can include anemia of chronic disease, iron deficiency anemia in patients with longstanding hematuria, renal insufficiency in patients with ureteral obstruction, transaminitis (elevation of liver transaminases), and elevation in bilirubin in patients with liver involvement.
• Hypercalcemia is rare and associated with poor prognosis typically associated with squamous differentiation.
• No tumor marker for bladder cancer.

Imaging
• Staging guidelines recommend abdomen and pelvis imaging with CT or MRI.
• Imaging of the upper tract collecting system
• Chest imaging
• Bone scan if clinical suspicion of bone metastasis by pain or alkaline phosphate elevation
• PET may be useful but not standard of care
• Evaluation of normal cardiac ejection fraction required for Adriamycin

Pathologic Findings
• Urothelial (formerly transitional cell) carcinoma is the most common subtype, and for which the most data exists.
• Many sun-exposed patients may have urothelial cancer with squamous or other foci of differentiation.
• Less common histologic subtypes are squamous cell carcinoma, adenoscarcinoma, and small cell carcinoma.

DIFFERENTIAL DIAGNOSIS
• Pelvic and retroperitoneal adenopathy
• Metaplastic: lymphoma (non-Hodgkin, Hodgkin, others), metastatic (adrenal, renal, uterine, prostate, urethral, penile, germ cell, cerebral, ovarian, uterine), G3 carcinoma (lymphoma), colo-rectal, melanoma
• Infectious/inflammatory:
• Granulomatous: TB, sarcoidosis, histoplasmosis, lymphogranuloma venereum, Ca, tuberculosis, disease, etc.
• Nongranulomatus: Viral, bacterial (if abscess in local area), viral histiocytosis, retroperitoneal fibrosis
• Other: Crypt retnopatetal masses (lymphocele, urinoma, hemmorhage) aneurysms
• Bone lesions
• Congenital (bone islands, others)
• Endothrombotic (thrombophlebitis, Paget disease)
• Neoplasm primary (ovarian, melanoma) or secondary (prostate, breast, kidney, lung, thyroid)
• Trauma fracture (stress or healing)
• Others: Autoimmune diseases, drugs (Vitamin D, fluoroquinolones, infection (osteomyelitis), inflammatory/fibrosed tissue (hepatocele, others))
• Pulmonary nodules
• Infections: fungal, septic emboli, fungal (histoplasmosis, etc.), parasitic, mycobacterial, inflammatory conditions (Wegner granulomatosis), pulmonary APN, mycobacteriosis, silicosis
• Malignant: Primary lung cancer, bladder cancer, choroid carcinoma, renal and thyroid cancer, melanoma, Ewing’s sarcoma

TREATMENT
GENERAL MEASURES
• Treatment of urothelial (transitional cell) carcinoma with platinum-based chemotherpay has increased survival but curative rates are limited. With good performance status and renal function, platinum-based combination chemotherapy is the initial approach (Grade 1A/1)
• “Futility” for platinum-based therapy is not well defined. Generally assessment of renal function (daily; mgn, hearing >25 dB at 2 contiguous frequencies), performance status (WHO/ECOG, performance status 2 or less), baseline peripheral neuropathy and cardiac function (New York Heart Association [NYHA] Class I or better)
• In the setting of impaired renal function correct reversible causes (obstruction, etc.)
BLADDER CANCER, UROTHELIAL, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)

MEDICATION

First Line
• Cisplatin-based chemotherapy combinations are the most active and superior to carboplatin regimens. Survival outcome is similar in patients treated with standard multiagent MVAC (methotrexate, vinblastine, doxorubicin, cisplatin) compared to cisplatin with gemcitabine (GC), with less toxicity in the GC group (1,2).

• High-dose intensity chemotherapy with MVAC plus GEMC (2nd line-MVAC) compared to standard MVAC led to a better overall response rate (94% vs. 59%) and improved survival (21.8% in the MVAC-MVAC vs. 13.5%) at 7 y. The toxicity profile of MV-MVAC was superior with better dose intensity, and thus established MV-MVAC as an alternative to standard M-VAC (3).

• MC chemotherapy is usually given every 14 days with the AC given along each 28 days.

• MV-MVAC is also referred to as “dose dense” MVAC (DD-MVAC) regimen given the same drugs at the same doses clsoe together, all drugs every 14 days with hematopoietic growth factor support and is recommended by the NCCN guidelines.

• Adding paclitaxel to cisplatin and gemcitabine, compared to GC led to a modest but not significant improvement in survival and is not endorsed for most patients (4).

• Some typical regimens reported in the literature include:
  - MVAC: Methotrexate (30 mg/m² on days 1, 15,
  - vinblastine (3 mg/m² on days 2, 15, 22),
  - doxorubicin (30 mg/m² on day 2), and
  - cisplatin (70 mg/m²) repeated every 28 days for 6 cycles.
  - GC: Gemcitabine (1,000 mg/m² days 1, 8, 15) plus cisplatin (70 mg/m² day 2), repeated every 28 days for a maximum of 6 cycles.

Second Line
• There is no standard therapy for patients who have disease recurrence or progression following 1st line cisplatin/pemetrexed or MVAC chemotherapy, and clinical trial participation is encouraged.

• Small nonrandomized studies support the use of the following agents:
  - Gemcitabine, folic acid, and platinum combinations
  - Gemcitabine: Rash and cytopenias
  - Paclitaxel: Fluid retention, neuropathy, myelosuppression

• Ureteral obstruction (tumor or lymphadenopathy) is a common complication that requires stenting or percutaneous nephrostomy drainage.

SURGERY/OTHER PROCEDURES
• Retrospective series support consideration of salvage surgery for patients who initially present with uncontrollable or metastatic disease with robust chemotherapy responses (5). Survival rates were consistently better in those with pathologic complete response to induction chemotherapy and in those with node only metastasis. (See Section 1 “Bladder cancer, urothelial, muscle invasive (clinical and pathologic T2/T3/T4)”).

ADDITIONAL TREATMENT
• Radiation Therapy
  - Palliative radiation therapy is an option for patients with painful bony metastasis.

• Additional Therapies
  - Studies suggest benefit of zolendronic acid or denosumab in patients with metastatic bladder cancer to bone (6).
  - Granulocyte colony-stimulating factor can help limit myelosuppression with cisplatin and others.

Complementary & Alternative Therapies
• Supportive care includes adequate nutrition and hydration, particularly for patients undergoing multiresistance therapy.

ONGOING CARE

PROGNOSIS
• For patients with metastatic disease, ECOG status ≥1, hemoglobin ≤10, and visceral involvement are prognostic for overall survival (survival 14.2 mo for those with none of these features vs. 1.7 mo with all 3 features).

COMPILATIONS
• Cisplatin: Nephrotoxicity, ototoxicity, peripheral neuropathy, fatigue.
• Adriamycin (in MVAC regimen): Cardiac toxicity.

Myelosuppression, neutropenic fever, sepsis, mucositis, nausea, and vomiting are common (up to 56% may require readmission for toxicity).

• Neutropenia (including life-threatening febrile neutropenia) associated with multimodality chemotherapy for bladder cancer. Granulocyte growth factor is standard in the high-dose intensity MVAC regimen, and is used to support patients on gemcitabine and platinum combinations.

• Gemcitabine: Rash and cytopenias

• Taxanes (ie, paclitaxel): Fluid retention, neuropathy, myelosuppression

• Urinary obstruction (tumor or nephropathy) is common and can be alleviated with urinary stenting or percutaneous nephrostomy drainage.

FOLLOW-UP

Patient Monitoring
• In patients with metastatic disease on chemotherapy, imaging should be performed every 2–3 mo to assess response. In patients with durable responses of chemotherapy, imaging should be done every 3 mo for the 1st 2 yr of response.

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
• Bladder Cancer, General
• Bladder Cancer, Nonurothelial
• Bladder Cancer, Squamous Cell Carcinoma

Codes
ICD-10
• C67.9 Secondary and unspecified malignant neoplasm of other specified sites.

ICD-9
• 188.9 Malignant neoplasm of bladder, part unspecified
• 196.9 Secondary and unspecified malignant neoplasm of lymph nodes, site unspecified
• 198.89 Secondary malignant neoplasm of other specified sites.

CLINICAL/SURGICAL PEARLS
• Single-agent chemotherapy provides low response rates of usually short duration.
• For 1st line chemotherapy, performance status and the presence or absence of visceral metastases are independent prognostic factors for overall survival.
• Blisk drains help limit cisplatin renal toxicity.
BLADDER CANCER, UROTHELIAL, MUSCLE INVASIVE (CLINICAL AND PATHOLOGIC T2/T3/T4) (MIBC)

Zachary L. Smith, MD
S. Bruce Malkowicz, MD, FACS

ASSOCIATED CONDITIONS
Those secondary to smoking (lung disease, other malignancies)

GENERAL PREVENTION
- Avoidance of exposure to cigarette smoke and industrial risk factors
- Appropriate and timely workup of both microscopic and/or gross hematuria (early diagnosis, not prevention)

DIAGNOSIS

HISTORY
- History of smoking or other risk factors
- Prior bladder tumors in hematuria
- Family history of BCA
- Signs and symptoms:
  - Painless hematuria (80%)
  - Intermittent symptoms (frequency, urgency, dysuria) (35%)
  - Stigmata of locally invasive or metastatic disease (pelvic pain/fullness, palpable mass, incontinence, weight loss, bone pain)

PHYSICAL EXAM
- General: Nutritional status, abdominal/pelvic masses, lymphadenopathy
- Digital rectal exam (male), bimanual pelvic exam (female), which can be performed under anesthesia

DIAGNOSTIC TESTS & INTERPRETATION
- Blood: CBC, electrolytes, LFT (elevated alkaline phosphatase suggests liver or bone involvement)
- Urine:
  - Urinalysis with microscopy
  - Urine: Urinalysis with microscopy
- Imaging:
  - Abdominal imaging
  - CT urogram (triple phase: Noncontrast, nephrographic, excretory) is the current standard of care
  - MR urogram acceptable, where available
- Bone scan

Pathologic Findings
- BCA will be analyzed by pathologist for grade and depth of invasion
- Grading (WHO/ISUP, 2004):
  - High-grade urothelial neoplasm of low malignant potential (well-differentiated)
  - Low-grade (moderate differentiation)
  - High-grade (poorly differentiated)
- Depth of invasion:
  - Into detrusor muscle (T2)
  - Into perivesical fat (T3)
  - Into adjacent structures (prostate, uterus, vagina, pelvic/abdominal wall) (T4)

DIFFERENTIAL DIAGNOSIS
- Gynecologic and other pelvic tumors directly invading bladder
- Adenocarcinomas more likely to be metastatic in origin
- Mass seen at bladder base on imaging is sometimes actually prostate median lobe

TREATMENT

GENERAL MEASURES
- Preoperative evaluation, as most patients also have significant cardiorespiratory disease
- Discuss treatment options and urinary diversion options
- If ileal conduit, meet with stoma therapy nurse pre-op and preop for care/teaching
- For continent diversion, pre-op teaching imperative
- If bladder preservation chosen, coordinate with radiation oncology and medical oncology

MEDICATION
First Line
- Intravesical treatments not used for MIBC
- Neoadjuvant/adjuvant therapy with radical cystectomy (RC) urothelial carcinoma primarily

Second Line
- Carboplatin substituted for cisplatin in renal insufficiency
- Mitomycin-C-fluorouracil is a newer regimen which has emerging data to support its use
- Taxanes also promising as both single and combination agent
Surgery/Other Procedures

- RC with pelvic lymphadenectomy and urinary diversion considered gold standard therapy for MIBC (2).
  - Complete extirpation and pelvic lymphadenectomy provide best chances for control and cure
  - Unusual frozen sections to ensure negative margins before urinary tract reconstruction is standard practice
  - Patients with ≥T4 disease on clinical staging may be offered neoadjuvant chemotherapy
  - RC gives additional benefit in metastatic disease, but may be palliative in patients with intractable hematuria or pelvic pain
  - Lymphadenectomy may be prognostic and therapeutic
    - Positive nodes in ~25%
    - Patients with limited nodal burden have higher survival rates
    - Extended lymphadenectomy (to include paraaortic) and (paraavalvar nodules) may improve survival
    - May identify patients most suited for adjuvant therapeutics

- Urinary diversion (1):
  - Options include continent, catheterizable stoma, continent orthotopic neobladder, or ileal conduit
  - Each with advantages and disadvantages
  - Real conduit used most commonly, least complications
  - Neobladders typically reserved for younger, motivated patients who are able to perform self-catheterization if needed

- Partial cystectomy:
  - One patient selection criteria: Stage T2 only, solitary lesion allowing for 2 cm margins, lack of CIS, not involving trigone or seminal tracts
  - Recurrence common within 2 yr
  - Still allows for lymphadenectomy

- Radical TURBT:
  - As a sole therapy, outcomes poor for MIBC
  - Usually palliative in patients who will not tolerate RC or systemic therapy (such as elderly with significant comorbidities)

- Urethrectomy:
  - Simultaneous (during RC) or delayed urethrectomy if CIS or tumor involves prostatic urethra, ducts, or stroma
  - Orthotopic reconstruction should not be made until negative frozen section distal urethral margin is examined

Additional Treatment

Radiation Therapy

- RT as a monotherapy is considered inferior to RC
- RT in combination with chemotherapy has a role in selected patients undergoing organ preservation (see below)

Additional Therapies

- Combination RT and chemotherapy after TURBT is more efficacious bladder preservation technique
- Developed for patients who are either not candidates for or refuse RC
  - Ideal candidates for bladder preservation:
    - Complete visual resection on TURBT
    - Solitary tumor
    - No hydroaexitis
    - < 5-yr overall survival > 30–50%; better in T2 disease than T3-4

- Complementary & Alternative Therapies

Ongoing Care

- Prognostic factors:
  - Tumor cell type (SCC and adenocarcinoma less favorable)
  - Tumor grade and stage
  - Disease-free survival correlates with stage
  - Node burden (≥8 positive and node density （>20%)) has worse prognosis

- Survival rates after RC:
  - Disease-free survival (5 yr) without positive nodes: 72% (82–84%) for pT2; 45% (49–57%) for pT3; 24% (25–6%) for pT4
  - Disease-free survival with positive nodes: 30% (15–48%)

Complications

- General:
  - Common due to local invasion and advancement of disease
  - Urinary obstruction, hydronephrosis
  - Hematuria, clot retention
  - Malnutrition, infection, etc.

- Associated with RC:
  - 90-day hospital readmission: 32%
  - 90-day mortality: >4% (5–10%)
  - Bowel obstruction (4–10%), ureteral obstruction (0–36%)

Follow-Up

Patient Monitoring

- Follow-up remains controversial and dependent on disease severity
  - T1/T2 disease: Semiannual physical exam, serum chemistries, and CXR with CT scan every 2 yr (T1) or yearly (T2)
  - T3/T4 disease: Exam, labs, and CXR every 3 mo

- If disease free at 5 yr, surveillance can be lessened
  - T3/T4 disease: Exam, labs, and CXR every 3 mo
  - T1/T2 disease: Semiannual physical exam, serum chemistries, and CXR with CT scan every 2 yr (T1) or yearly (T2)

- Follow-up includes patients who will not tolerate RC or systemic therapy (such as elderly with significant comorbidities)

- Consider urethral washing or cystoscopy

ASSOCIATED CONDITIONS
- The majority of bladder cancer diagnosed in US has no other associations.
- In Egypt and regions in SE Asia, chronic bladder irritation from Schistosoma infection can lead to squamous cell carcinoma, as can chronic bladder irritation or inflammation, such as from chronic indwelling catheter use.

GENERAL PREVENTION
- Smoking cessation
- Limit or modify chemical exposure

RISK FACTORS
- Cigarette smoking
- Chemical and occupational exposure association
- Cigarette smoking
- Chemical and occupational exposure association
- Cytogenetic abnormalities:
  - Inactivating mutation in p53, p21, or Rb (MIBC)
  - Loss of chromosomes 17q, 5q, 3p (MIBC)
  - Multifactorial polygenic
  - Autosomal dominant
- Alterations in genes which contribute to toxin breakdown within the bladder (such as GST and AHR), may make some more likely to develop bladder cancer.
- Tumor multifocality and the high rate of recurrence of urothelial cancer within the bladder, ureters, and renal pelvis in patients with a bladder cancer history can be due to the field effect in part from toxin exposure.
- T2: Muscularis propria invasion
- T3: Perivesical tissue invasion
- T4: Invasion of pelvic structures (eg, prostate, small bowel, bladder, vagina, pelvic side wall, or abdominal wall)

EPIDEMIOLOGY
Incidence (1)
- 74,690 new cases of bladder cancer will be diagnosed in 2023.
- 500,000 in US (all stages)

Prevalence
- >50,000 in US (all stages)

DIAGNOSIS
- Gross or microscopic hematuria is the most common presenting sign.
- Dysuria, frequency, and urgency are common.
- Symptoms of locally advanced disease such as pelvic pain and constipation.
- Flank pain or renal insufficiency due to ureteral obstruction by tumor.

PATHOPHYSIOLOGY
- Tumor multifocality and the high rate of recurrence of urothelial cancer within the bladder, ureters, and renal pelvis in patients with a bladder cancer history can be due to the field effect in part from toxin exposure.

DIAGNOSTIC TESTS & INTERPRETATION
- Physical exam
- History
- General prevention
- Smoking cessation
- Limit or modify chemical exposure

BASICS

DESCRIPTION
- Bladder cancer is invasive, invasive bladder cancer (T2, T3, 4 MIBC) is much less common than noninvasive bladder cancer.
- May present with de novo invasive cancer, a minority progress from superficial bladder cancer.
- Radical cystectomy for muscle invasive bladder cancer is potentially curative, up to 50% of patients will develop recurrence within 1 yr.
- This high recurrence has led to the increasing use of neoadjuvant chem before cystectomy.
- Neoadjuvant cisplatin-based chemo has improved survival in radical cystectomy alone.

EPIDEMIOLOGY
Incidence (1)
- 74,690 new cases of bladder cancer will be diagnosed in 2023.
- 500,000 in US (all stages)

Prevalence
- >50,000 in US (all stages)

- T2: Muscularis propria invasion
- T3: Perivesical tissue invasion
- T4: Invasion of pelvic structures (eg, prostate, small bowel, bladder, vagina, pelvic side wall, or abdominal wall)
ADDITIONAL TREATMENT

**Radiation Therapy**
- Multimodality treatment with chemo-radiotherapy can be considered for patients who are medically inoperable or selected patients who wish for bladder preservation (8).
- If T2–T3, up to 5 cm, no carcinoma in situ, no hydroaestrosis, complete TURBT reaction, T3–T4, functional bladder at baseline.

**Neoadjuvant chemo** followed by cystectomy and chemo-radiotherapy have not been compared head to head in a prospective trial.

**Additional Therapies**
- Multidisciplinary evaluation should be considered to assess best plan of care
- For patients who have received standard cisplatin-based neoadjuvant chemo, there is currently no recommendation for adjuvant chemo following cystectomy
- For patients with invasive or node positive disease following cystectomy who did not receive neoadjuvant chemo, adjuvant platinum-based therapy should be considered
- Positive surgical margins can increase risk of local failure; consider adjuvant chemotherapy

**Complementary & Alternative Therapies**
- N/A

**ONGOING CARE**

**PROGNOSIS**
- Patients with pathologic complete response (pT0) at radical cystectomy have superior relapse free and overall survival outcomes compared to those with residual invasive disease
- 10.8% complete pathologic downstaging

**COMPLICATIONS**
- Cystitis, Nephrotoxicity, astrocitosis, peripheral neuropathy, and fatigue
- Adjuvant (in NAAC). Cardiac toxicity
- Neutropenia, including life threatening febrile neutropenia is associated with multimodality chemo for bladder cancer. Granulocyte growth factor is standard in the high-dose intensity HDM-EC regimen, and can be used to support patients on GC/platinum combinations
- GC: Rash and cystitis
- Ureteral obstruction (tumor or nodes): Alleviate with ureteral stenting or percutaneous nephrostomy to improve renal function
- 30-day perioperative mortality following cystectomy approximately 1%; average 30-day readmission rate 21–32%
- Perioperative morbidity following cystectomy: Infe, blood loss, infection, thromboembolism, wound complication, ostomy complications.

**FOLLOW-UP**

**Patient Monitoring**
- Following radical cystectomy, imaging of the chest, abdomen and pelvis including upper tract evaluation and CNE and electrolyte assessment should occur every 3–6 mo. Based on recurrence risk for the first 2 yr, then clinically indicated
- Urine cytology and electrolytes should be monitored every 3–6 mo. Based on recurrence risk for the first 2 yr, then as clinically indicated
- Continent diversion: Monitor 812 deficiency

**Patient Resources**
Bladder Cancer Advocacy Network
http://www.bcan.org

**CODES**

ICD-O-MORPH
- 188.9 Malignant neoplasm of bladder, part unspecified

ICD-O-MORPH
- 188.9 Malignant neoplasm of bladder, unspecified

**CLINICAL/SURGICAL PEARLS**
- Outcomes after radical cystectomy indicate increased survival in patients who had more, rather than fewer, lymph nodes resected
- Patients with pathologic complete response following neoadjuvant chemotherapy appear to have the best long-term survival.
Carcinoma in situ (CIS) of the bladder is a flat, multifocal, “velvety” lesion of the urothelium. CIS is a flat, high-grade tumor that is confined to the mucosa. It can be occult and diagnosed by random biopsies of normal-appearing mucosa. Although it can occur alone, it most often seen with concurrent high-grade papillary lesions. CIS is considered high grade and aggressive with a propensity to invade the bladder wall and metastasize.

**EPIDEMIOLOGY**

**Incidence**

True incidence is not known given the flat superficial nature of this lesion, which can be destroyed by cautery effect during transurethral resection of bladder tumor (TURBT).

**Prevalence**

- Occurs as isolated CIS in 3–5% cases
- Estimated 5–10% of patients with noninvasive urothelial carcinoma have CIS
- 45–65% patients with invasive urothelial carcinoma have CIS

**RISK FACTORS**

- No risk factors specific for CIS beyond that of urothelial carcinoma
- Tobacco smoking
- Occupational exposure
- Medications
- Pelvic radiation
- Medications
- Occupational exposure
- Smoking history
- Family history of bladder cancer
- History of bladder cancer
- Irritative voiding symptoms—dysuria commonly
- Presence of gross hematuria
- Avoid occupational exposures
- Smoking cessation

**PATHOPHYSIOLOGY**

- CIS usually multifocal and can occur in the upper tracts, prostatic ducts, and urethra as well as the bladder
- Natural history—highly aggressive
- Progression to NMIBC in 54–83% of untreated cases
- Increase risk of recurrence if found with NMIBC papillary lesions.
- Bacillus Calmette-Guerin (BCG) reduces risk of progression by 35% compared with other intravesical therapies (1,3)
- BCG confers disease-free rate approximately 51% at 3–7 yr (1)
- If concurrent muscle-invasive lesion, prognosis and treatment depends on invasive lesion

**ASSOCIATED CONDITIONS**

- NMIBC (Ta,T1)
- Invasive bladder cancer (T2,T3,T4)

**GENERAL PREVENTION**

- Smoking cessation
- Avoid occupational exposures

**DIAGNOSIS**

**HISTORY**

- Age and sex
- Presence of gross hematuria
- Irritative voiding symptoms—dysuria commonly occurs with CIS
- History of bladder cancer
- Family history of bladder cancer
- Smoking history
- Occupational risk factors

**PHYSICAL EXAM**

- Usually unremarkable

- Biannual exam should be performed at time of cystoscopy/TURBT—if CIS is found in presence of advanced stage/invasive bladder cancer may appreciate palpable mass

**DIFFERENTIAL DIAGNOSIS**

- Noninvasive urothelial carcinoma
- Adenocarcinoma
- Metastatic disease

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis, including microscopic evaluation
- Urethral cytology—highly specific and sensitive (>90%) for detecting CIS and high-grade urothelial carcinoma (5)
- Urilocystin, HA-HAase, and BLCA-4 have a high sensitivity to detect CIS however should not replace classic urine cytology (1, Grade B)

**IMAGING**

- No imaging specific for diagnosing CIS
- Renal/bladder ultrasound (US): Detects hydronephrosis that may be caused by ureteral obstruction from bladder tumor; bladder US can visualize larger bladder tumors
- Computed tomography (CT) urogram: Triple phase CT abdomen/pelvis is the gold standard for evaluation of pseudo-gross hematuria; can detect more advanced bladder tumors, hydronephrosis, and upper tract filling defects that may represent upper tract urothelial carcinoma.

**Diagnosis of Procedure/Surgery**

- Cystoscopy with bladder biopsy
  - Appearance can be flat, grossly erythematous, granular or cobblestone mucosa or visually normal
  - May be performed in office at initial visit
  - TURBT under general or spinal anesthesia may be required if papillary bladder tumor present
  - Retrograde urography also should be performed to assess the upper tracts if not already evaluated with a CT urogram.
  - Positive cytology with no visible tumor and negative random bladder biopsies suggests disease outside of bladder
  - Biopsy of prostatic urethra indicated
  - Selective cystoscopy from upper tracts; evaluate for urothelial carcinoma/CIS of renal pelvis or ureters. CIS of upper tracts suspected in absence of solid tumor and with positive cytology, rarely able to obtain adequate biopsy to confirm CIS histologically

- Fluorescent “Blue light” cystoscopy
  - More sensitive than conventional white light cystoscopy for detecting CIS
  - In a prospective study additional detection rate of 20% for all tumors and 23% for CIS
  - False positives can result in the presence of inflammation, recent TUR, or BCG instillation

**Pathologic Findings**

- Arias from surface uroepithelium
- Severe cystitis, atypia and mucosal aphasia (2)
- Large uniform hypochromatic nuclei
- Mitotic activity common
- Thought to be a precursor of invasive disease
- Some pathologists use the term “severe dysplasia” to describe CIS

**DIFFERENTIAL DIAGNOSIS**

- Nonurothelial cancers (squamous cell carcinoma, adenocarcinoma)
- Inflammatory lesion from prior radiation, intestinal cystitis, infection.
ADDITIONAL TREATMENTS

SURGERY/OTHER PROCEDURES

- **TURBT**—Resection of all visible papillary bladder tumors is essential prior to BCG therapy.
- For CIS refractory to intravesical therapy—radical cystectomy.
  - Disease-specific survival rates excellent if cystectomy performed early (instead of BCG instillation), however 40–50% could be overtreated.

MEDICATION

- **BCG**—live suspension of the attenuated Mycobacterium bovis vaccine strain
  - Standard of care for CIS
  - Therapy initiated no earlier than 2–4 wk after TURBT to give urothelium time to heal and prevent systemic complications of BCG
  - Administered as induction therapy—6 consecutive weekly bladder instillations; then maintenance treatment recommended for at least 1 yr (1) (Grade A)
  - BCG has the highest complete response rate and durable disease-free rates among all intravesical treatments (1) (Grade A)
  - Initial response rates approximately 70–90%; however up to 30% of patients will recur
  - Response to BCG instillation should be assessed at 3 mo
    - If no response can give another 6-wk course of BCG vs. proceed to radical cystectomy
    - Approximately 50% will respond to second course of BCG (1) (Grade B)

SECOND LINE

- **Intravesical chemotherapy**
  - Mitomycin C—an alternative for patients who cannot tolerate BCG.
  - Valrubicin—an option for poor surgical candidates with BCG-refractory disease—durable disease-free rates of all intravesical therapies.
  - Has side effect of dysuria and can be intolerable in some patients
  - Usually experienced within the first 6 mo of treatment.

FOLLOW-UP

- **Patient Monitoring**
  - At 3 mo patients should have urocytology and urine cytology. If negative, this should be repeated every 3 mo x 2 ye, every 6 mo thereafter until year 5 and then yearly (3)

ICD9

- 189.7 Carcinoma in situ of bladder

ICD10

- D09.0 Carcinoma in situ of bladder

CLINICAL/SURGICAL PEARLS

- Urine cytology is the best marker (>90% sensitivity/specificity) for diagnosis of CIS.

- Positive cytology in absence of visible bladder lesions—differential includes CIS bladder, prostatic urethra, or upper tract urothelial carcinoma.

- BCG is the treatment of choice for CIS of the bladder; highest response rate and most durable disease-free rates of all intravesical therapies.

- To prevent systemic complications of BCG do not administer after TURBT until urothelium healed (approximately 2 wk).

- For BCG refractory CIS: A second induction course can be administered vs. proceeding immediately to radical cystectomy.
BASICS

DESCRIPTION
- Bladder injury during surgery can be either intraperitoneal or extraperitoneal.
- The bladder is the urologic organ most subject to iatrogenic injury.
- Described during open, endoscopic, laparoscopic, or robotic procedures.
- May be blunt or sharp dissection, trosa, or electrocautery injury.
- Needle or trocar passage during transvaginal tape or dissection.
- Described during open, endoscopic, laparoscopic, or robotic procedures.
- Cystoscopy with overdistention and transurethral bladder tumor resections are also high risk for bladder perforation injury.

EPIDEMIOLOGY

Incidence (1,2)
- Intraoperative bladder injuries account for:
  - Laparoscopic injuries (0.2–8.3%)
  - Intraperitoneal (38–40%)
  - Extraperitoneal (53–56%) of injuries

Prevalence

Risk factors associated with specific conditions and procedures based on AUA review
- General factors
  - Previous caesarean delivery
  - Presence of labor
  - Presence of fetal part > +1
  - Fetal weight > 4 kg
  - Hysterectomy
  - Malignancy
  - Endometriosis
  - Prior pelvic surgery
  - Perforated anti-incontinence or pelvic organ prolapse surgery

- Risk factors associated with specific conditions and procedures based on AUA review

- Prior pelvic surgery
- Perforated anti-incontinence or pelvic organ prolapse surgery
- General surgery
- Malignancy
- Diverticulitis
- Inflammatory bowel disease

ASSOCIATED CONDITIONS
- Bladder cancer
- Prostate benign and malignant tumors
- Pelvic anatomic anomalies
- Prior pelvic surgery or radiation
- Pelvic trauma
- Tissue fibrosis or inflammation (eg, radiation, chronic catheter)

GENERAL PREVENTION
- Decompress bladder with a catheter placed before initial incision or trocar placement for laparoscopic cases
- Initial use of vesicure needle for insufflation
- Small bladder perforation not as significant as large perforation
- "Anatomic" trocar technique

Familiarity with bladder anatomy can minimize risk:
- Pediatric bladder is primarily intraperitoneal.
- Adult bladder is retroperitoneal and extraperitoneal.
- Peritoneum is clefted to bladder.
- Bladder is attached broadly and not as bladder neck.
- Bladder wall consists of 3 layers: mucosa, submucosa, muscularis.
- Ureters attached posteriorly in trigone
- Perforate bladder injury or TURBT with bladder at mid filling
- Avoid over or underdistention that can increase risk of perforation of bladder

DIAGNOSIS

HISTORY
- Determine any prior surgical or other interventions that can increase the risk of iatrogenic bladder injury
- Past surgical history such as bladder neck suspension, prostatectomy, partial cystectomy, urethral neobladder, any lower abdominal surgery that may result in the bladder adhering to the posterior fascia
- Prior pelvic radiation
- History of neurogenic bladder

PHYSICAL EXAM
- Intraperitoneal:
  - Findings may be subtle. Need high degree of suspicion
- Blood or gas in Foley, especially during transperitoneal laparoscopic procedure
  - Anesthesia may be first to recognize if monitoring catheter collection bag
- Urine in wound
- For transurethral surgery: Intraperitoneal abdominal distention/lifidity may be noted if hydrostatic irrigation is being used, patient may develop signs/symptoms of TUR syndrome
- Postoperative:
  - Distended abdomen
  - Peritonitis and abdominal rebound pain
  - Decreased urine production; oliguria or anuria
  - Abdominal/pelvic aches
  - Urine leakage from wound
  - Bloody urine
  - Fever

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- With urinary ascites elevation in serum BUN and creatinine as well as hyperkalemia and hypotension can be seen
- Elevated creatinine over serum level observed with urine leak due to systemic absorption
- Drain fluid sent for creatinine
- Urine vs. serum

Imaging
- Postoperative diagnosis (3):
  - Extraperitoneal Injury: Contrast contained in the extraperitoneal space
  - Intraperitoneal Injury: Contrast extravasates between loops of small bowel and the anterior paramesonephric fascia

CT cystogram can be done using standard technique or CT imaging with postcontrast evaluation (3):
- 300 cc gravity filling
- 3-view cystogram or CT cystogram
- All cystograms must include a postcontrast evacuation study to evaluate for residual contrast outside of the bladder
- SC can identify urinoma
- CT for pelvic ‘‘urinary’’ ascites or urinoma
- Intraperitoneal diagnosis during transurethral surgery. Intraperitoneal cystogram can be obtained
Diffuse detrusor usually causes urine leak
Rupture through mucosa, submucosa, and muscularis

**Diagnostic Procedures/Surgery (1,4)**

- Intraoperative extraperitoneal injury:
  - Initial catheter drainage with antibiotics
  - Exploratory laparotomy with repair
  - Foley or 2-layer repair
  - Open bladder/2-layer repair
  - 1-layer laparoscopic or robotic repair
- Intraperitoneal perforation
  - Usually managed with catheter drainage and close monitoring
  - Large perforations complicated by symptomatic collections require drainage, with or without formal closure of the perforation
- Bladder perforation during midurethral sling or transsacral mesh placement
  - Sling reinsertion and urethral catheterization
  - 11–12 days should be performed (4,8)

**ADEQUATE TREATMENT**

- For most bladder injuries Foley catheter for 24 hr
- Prompt recognition improves opportunity for formal closure of the perforation
- Prognosis worse if delayed diagnosis

**ADDITIONAL TREATMENT**

- In the setting of any bladder perforation during TURBT
- Intravesical postoperative chemotherapy should not be administered

**ONGOING CARE**

**PRONOSIS**

- Extraperitoneal: Usually heals with Foley catheter drainage and without further intervention
- Intraperitoneal: Good prognosis if identified intraperitoneally and repaired. Prognosis worse if delayed diagnosis

**COMPLICATIONS**

- Pericystitis or abscess
- Fever
- Hypotension

**FOLLOW-UP**

- Patient Monitoring
  - Foley catheter or suprapubic tube to monitor urine output
  - Usually no need for outpatient antibiotics

**REFERENCES**

**ADDITIONAL READING**

- See Also (Topic, Algorithm, Media)
  - Bladder Trauma
  - Trocar Syndrome
  - Ureter, Intraoperative Injury
  - Ureter, Trauma

**CODES**

- N99.72 Accidental puncture & laceration of a GU sys org during a GU sys procedure
- N99.71 Accidental puncture or laceration during a GU sys procedure
- 959.73 Accidental puncture & laceration of GU sys procedure during cath procedure
- 959.79 Accidental puncture & laceration of a GU sys procedure during other procedure
- 537.23–A Laceration of bladder, initial encounter

**PEARLS**

- Intraoperative visual inspection is a reliable method of assessing bladder injury
- Extraperitoneal: Usually heals with Foley catheter drainage and without further intervention
- Intraperitoneal: Good prognosis if identified intraperitoneally and repaired. Prognosis worse if delayed diagnosis
- All cystograms must include a postcontrast evacuation study to evaluate for residual contrast outside of the bladder.
BLADDER OUTLET OBSTRUCTION (BOO)

Michael J. Naslund, MD
Garjae D. Lavien, MD

DESCRIPTION

Bladder outlet obstruction (BOO) refers to a pathologic obstruction to urinary flow. Definitions include the following:

- A reduction in urinary flow to <12 cc/s during a sustained detrusor contraction of over 40–50 cm H₂O
- BOO index >40 on the International Continence Society nomogram based on urodynamic testing

EPIDEMIOLOGY

Incidence

2.2–6.8 events of acute urinary retention per 1,000 person years (1)

Prevalence
None

RISK FACTORS

- Increasing age
- Microscopic BPH starts as early as the 30s but clinical BPH usually presents after the age of 50
- Infection
- Urethral trauma
- Pelvic radiation
- Prior urologic procedures

GENETICS

None

PATHOPHYSIOLOGY

BOO can be due to both static and dynamic factors:

- Static factors:
  - Constricted outlet by enlarged prostatic tissue, bladder neck contracture, or urethral stricture
  - Outlet obstruction leads to detrusor hypertrophy and the symptoms of BOO

ASSOCIATED CONDITIONS

- BPH
- Urethral stricture disease
- Detrusor sphincter dyssynergia

GENERAL PREVENTION
None

DIAGNOSIS

HISTORY

- Detailed description of obstructive voiding symptoms consistent with BOO
- Slow urinary stream
- Urinary hesitancy
- Intermittent urinary stream
- Straining to void
- Sense of incomplete bladder emptying
- Urinary retention
- History of irritative symptoms
- Medical history of gynecologic, neurologic, and GI illness
- Past surgical history for pelvic and spinal procedures
- Medication review for anticholinergics, u-agonists, psychotropic agents
- Voiding diary
- International Prostate Symptom Score

PHYSICAL EXAM

- Abdominal palpation:
  - Palpate for bladder distention (>150 cc), needed to be palpable in an adult
- Rectal examination:
  - Note any findings suspicious for cancer: Nodules, firmness, and asymmetry
- Assess anal sphincter tone
- Pelvic exam (women) for pelvic organ prolapse and urethral diverticula
- Neurologic exam for gross defects

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA:
  - If elevated, consider prostate cancer, prostatic inflammation, benign prostatic hyperplasia
- Urinalysis:
  - If hematuria or urinary infection is present, further evaluation is necessary (see Chapter on “Hematuria, Gross and Microscopic, Adult”)
  - Renal and bladder US
- Urine culture
- Creatinine
- Test is necessary unless patient is in urinary retention

Imaging

- Radiographic and bladder US:
  - Evaluate for hydronephrosis if there is renal insufficiency
  - Allows noninvasive determination of PVR
- Upper tract imaging with CT urogram to evaluate causes of hematuria
  - Unilobar:
    - Measure peak flow, demonstrate voiding pattern, and voided volume
    - Peak flow <10–12 cc/s (for voided volume >150 cc) is suggestive of obstruction, although an uncorrectable bladder cannot be ruled out

- Cystoscopy: Endoscopic evaluation of urethra and bladder
- Videourodynamics: Fluoroscopy combined with urodynamics
- ICS nomogram is the most widely used
- Videourodynamics: Fluoroscopy combined with urodynamics

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease
- BOO after incontinence surgery
- Prostatic obstruction (BPH)
- Most common etiology of BOO in men
- Primary bladder neck obstruction
- Infection:
  - Prostatitis, intraurethral condyloma (men and women), periurethral abscess
- Neurogenic:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- Medications that affect bladder contractility:
  - Anticholinergics, antihypertensives, 
- Neuropathy:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- BOO after incontinence surgery
- Prostatic obstruction (BPH)
- Most common etiology of BOO in men
- Primary bladder neck obstruction
- Infection:
  - Prostatitis, intraurethral condyloma (men and women), periurethral abscess
- Neurogenic:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- Medications that affect bladder contractility:
  - Anticholinergics, antihypertensives, 
- Neuropathy:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- BOO after incontinence surgery
- Prostatic obstruction (BPH)
- Most common etiology of BOO in men
- Primary bladder neck obstruction
- Infection:
  - Prostatitis, intraurethral condyloma (men and women), periurethral abscess
- Neurogenic:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- Medications that affect bladder contractility:
  - Anticholinergics, antihypertensives, 
- Neuropathy:
  - Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- BOO after incontinence surgery
- Prostatic obstruction (BPH)
- Most common etiology of BOO in men
- Primary bladder neck obstruction
- A suprapubic tube is used if a urethral catheter cannot be placed (severe stricture or BPH) or urethral catheter is contraindicated (acute prostatitis).
- Long-term treatment of BOO is medical and surgical.
Therapies

N/A

Radiation Therapy

ADDITIONAL TREATMENT

Saw Palmetto (Serenoa Repens)

ADDITIONAL READING

If a male patient has lower urinary tract symptoms check to ensure a low post-void residual which generally confirms that treatment is not necessary.

Strong consideration should be given for evaluation for multiple sclerosis in young females with new onset urinary retention.

MEDICATION

First Line

- α-Blockers: Rapidly relax the smooth muscle of the bladder neck and prostate without impairing bladder contractility
  - Alfuzosin (10 mg/d)
  - Tamsulosin (0.4 mg to max 0.8 mg)
  - Silodosin (8 mg/d)
  - Terazosin (start 1 mg/d to max 20 mg)
  - Flutamide (5 mg/d)
  - Dutasteride (0.5 mg/d)

Second Line

- Phosphodiesterase-5 inhibitors (PDE5i) in males:
  - Sildenafil (50 mg to max 100 mg)
  - Tadalafil (20 mg)
  - Vardenafil (20 mg)
- α-Reductase inhibitors in males: Effective in larger glands (>40 cc) to reduce prostate size, improve symptoms, and reduce progression risk:
  - Finasteride (5 mg/d)
  - Dutasteride (0.5 mg/d)

SURGERY/OTHER PROCEDURES

- Urethral stents
- Clean intermittent catheterization
- Prostatic stents
- Bladder diverticula and fascial bladder
- Transabdominal prostatectomy
- Transperineal prostatectomy
- Transurethral prostatectomy
- Transurethral microwave therapy
- Transurethral needle ablation
- Open excision (with primary anastomosis, grafts, or flaps)
- Urethral dilation
- Urethral stents
- Transvaginal sphincterotomy
- Ureteral stents
- Urethral dilatation
- Urethral incision
- Urethral stents
- Urethral dilatation
- Urethral incision
- Urethral diverticulitis and fascial bladder
- Postobstructive diuresis:
  - Occurs with severe BOO and bilateral ureteral obstruction due to urinary retention
  - Severe hydronephrosis and renal failure
  - Serum electrolytes must be monitored closely

FOLLOW-UP

Patient Monitoring

- Periodic follow-up visits to assess symptom progression (PFS)
- Yearly urology and PSA measurement
- Serial measurement of uroflow and PVR urine
- Causal on the possibility of progression of symptoms and complications
- Management of BPH does not eliminate the risk of developing prostate cancer

Patient Resources

- Urology Care Foundation: www.urologyhealth.org

REFERENCES

ONGOING CARE

PROGNOSIS

Excellent with definitive management

COMPLICATIONS

- Urinary retention
- Bladder stones
- UTIs
- Sphincterotomy
- Dysuria
- No difference in reduction of lower urinary tract symptoms, and reduce progression risk:
- Finasteride (5 mg/d)
- Dutasteride (0.5 mg/d)

ADDITIONAL TREATMENT

Radiation Therapy

- Alpha-blockers: Rapidly relax the smooth muscle of the bladder neck and prostate without impairing bladder contractility
- Phosphodiesterase-5 inhibitors (PDE5i) in males:
  - Sildenafil (50 mg to max 100 mg)
  - Tadalafil (20 mg)
  - Vardenafil (20 mg)
- Alpha-reductase inhibitors in males: Effective in larger glands (>40 cc) to reduce prostate size, improve symptoms, and reduce progression risk:
  - Finasteride (5 mg/d)
  - Dutasteride (0.5 mg/d)
- Second Line
  - Phosphodiesterase-5 inhibitors (PDE5i) in males:
    - Tadalafil only FDA-approved by the FDA for treatment of LUTS in the setting of BPH with or without coexisting erectile dysfunction (ED)

SURGERY/OTHER PROCEDURES

- Urethral stents
- Clean intermittent catheterization
- Prostatic stents
- Bladder diverticula and fascial bladder
- Transabdominal prostatectomy
- Transperineal prostatectomy
- Transurethral prostatectomy
- Transurethral microwave therapy
- Transurethral needle ablation
- Open excision (with primary anastomosis, grafts, or flaps)
- Urethral dilatation
- Urethral incision
- Urethral diverticulitis and fascial bladder
- Postobstructive diuresis:
  - Occurs with severe BOO and bilateral ureteral obstruction due to urinary retention
  - Severe hydronephrosis and renal failure
  - Serum electrolytes must be monitored closely

FOLLOW-UP

Patient Monitoring

BLADDER TRAUMA

Hunter Wessells, MD, FACS

DESCRIPTION
Bladder trauma generally comprises blunt and penetrating types of injury.
When not distended, bladder is protected from injury by bony pelvic
Pelvic fracture and bladder distention increase risk of traumatic injury.
Important to distinguish between extraperitoneal (EBR), intraperitoneal (IBR), and combined EBR/IBR.
Urogenic bladder injury is discussed in the section “Bladder Injury, Intraoperative.”

EPISTEMOLOGY
Incidence
1.6% of blunt abdominal trauma
Prevalence
Unknown

RISK FACTORS
Motor vehicle crashes (MVCs)
– Falls
– Industrial trauma (pelvic crush injury)
– Penetrating injuries to lower abdomen
– Bladder outlet obstruction
– Alcohol intoxication (bladder distention and decreased sensorium)
– Pelvic fracture
– 80% of bladder injuries associated with pelvic fracture
– 6% of patients with pelvic fracture sustain a bladder injury
– Urinalysis (UA) usually present

Genetics
N/A

PATHOPHYSIOLOGY
The bladder is generally well protected from blunt trauma unless significantly distended.
In an adult, the bladder lies in the true pelvis, but can rise to umbilicus when full.
In a child, bladder lies in abdomen and more prone to injury.
EBR or combined EBR/IBR
Pelvic fracture leads to shearing injury from bone fragment or compression with rupture
– Direct injury from penetrating trauma
– BFR
– How to lower abdomen in the presence of a full bladder

ASSOCIATED CONDITIONS
– Bladder neck injury
– Pelvic fracture
– Solid abdominal organ injury
– Urinary injury

GENERAL PREVENTION
– Avoid high risk activity
– Seatbelt proper positioning and use

DIAGNOSIS

HISTORY
– Type of blunt trauma to pelvis
– Associated injuries
– Penetrating injury, type of knife if known
– Gross hematuria
– Alcohol use
– Past urologic history
– Compliant:
– Location of lower abdominal pain
– Urinary retention
– Dysuria or voiding complaints

PHYSICAL EXAM
– Abdominal distention
– Lower abdominal/pelvic turgor
– Peristalsis
– Rectal and vaginal exam (assess integrity)
– Blood at meatus

– Site/extent/trajectory of penetrating objects
– Site/extent of abdominal/pelvic bruising
– Seatbelt sign
– Pelvic fracture and bladder distention increase risk of traumatic injury
– Bladder outlet obstruction
– Alcohol intoxication (bladder distention and decreased sensorium)
– Pelvic fracture
– 80% of bladder injuries associated with pelvic fracture
– 6% of patients with pelvic fracture sustain a bladder injury

ALERT
Gross hematuria is the hallmark sign of injury to the bladder.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
– Urinalysis (UA): Blood usually present
– Serum creatinine can be elevated with IBR due to intraperitoneal resorption of urine
– Hypertension, hypotension, uremia, azotemia can also be seen with urinary extravasation into the peritoneum
– CBC (look for leukocytosis and anemia)

Imaging
– Indications for performing cystography:
– Blunt trauma
– Pelvic ring fracture with gross or microscopic (≥3 or >10 RBC/HPF) hematuria
– Gross hematuria in presence of otherwise unexplained free intraperitoneal fluid
– High clinical suspicion (pelvic fluid collection, inability to void, elevated serum creatinine, abdominal distention, suprapubic tenderness, intesinocutaneous or unexplained, poorly functioning
– Foley catheter, displaced obturator ring fracture, or large public symphysis diastasis
– Perforating injury
– Trajectory suggests bladder injury
– Involvement of buttock, pelvic, or lower abdomen with any degree of hematuria
– High clinical suspicion

If urethral injury is suspected, this should be assessed preoperatively (CT with delayed images) or intraoperatively (retrograde pyelography/direct inspection)
When combined upper and lower tract urologic injuries are suspected, upper tract contrast study should be performed prior to cystogram (retained bladder contrast in abdomen or retroperitoneum can obscure upper tract pathology)

Diagnostic Procedures/Surgery
– Cystogram is easy to do and highly sensitive
– CT cystogram
– At least as sensitive as conventional cystography for diagnosing bladder rupture
– Dilute contrast to limit artifact (1:2)
– Postobstructive films not necessary
– Excellent visualization of bladder neck
– Readily identify foreign bodies
– Conventional cystoscopy
– Dilute contrast 1:2
– Scout, 40 oblique, and retrograde films
– For both CT and conventional cystography, fill bladder to capacity (at least 350 mL) in an adult, or determine by formula: (Age in years + 2) × 30.

ALERT
CT with delayed images is inadequate for the diagnosis of bladder injuries when bladder injury is suspected, a cystogram is mandatory.

Pathologic Findings
Injured tissue typically remains healthy, though there is potential for local ischemia (particularly if angio-embolization was performed for pelvic bleeding)

DIFFERENTIAL DIAGNOSIS
– Bladder contusion
– Urinalysis
– Renal or urethral injury

TREATMENT

GENERAL MEASURES
Stabilize patient if major trauma present

MEDICATION

First Line
For nonoperative management of EBR, antibiotics with gram-positive and gram-negative coverage are recommended while catheter is indwelling

Second Line
SPA
When associated with significant pelvic bleeding, open pelvic fractures, and abdominal solid organ injury, supportive care is indicated while more urgent injuries are temporized.

- **IBR**
  - Laceration is typically large (6–8 cm), at dome
  - Nonoperative management generally contraindicated secondary to size of defect and morbidity of chemical peritonitis
  - Should be closed in 2 layers with absorbable suture via midline incision
  - Laparoscopic repair has been reported in stable patients with no other injuries
  - Drain is not necessary
  - Foley catheter 7–10 days, with cystogram to confirm absence of extravasation

- **EBR**
  - Nonoperative management
  - Acceptable in the appropriate patient, but higher complication risk
  - 20-French or larger catheter
  - Cystogram after 10–14 days
  - Antibiotics with gram-positive and gram-negative coverage while catheter is indwelling
  - Contraindications to nonoperative management:
    - Inadequate catheter drainage
    - Vaginal or rectal injury
    - Bladder neck injury
    - Concomitant urethral injury
    - Internal fixation of pelvic fracture
    - Stable and undergoing laparotomy

**ADDITIONAL TREATMENT**

**Radiation Therapy**

**Additional Therapies**

**Complementary & Alternative Therapies**

**ONGOING CARE**

**PROGNOSIS**

- Prompt diagnosis and appropriate management allow excellent results and minimal morbidity.
- Complications usually are associated with delay in diagnosis and management.

**COMPLICATIONS**

- Unrecognized injury can result in fistula, sepsis, ileus, incontinence, and stricture.

**FOLLOW-UP**

- Monitor for signs/symptoms of:
  - Pelvic bleeding
  - Unrecognized abdominal injury
  - UTI
  - Urinary leak

**Patient Resources**

- www.urologyhealth.org/urology/index.cfm?article=99

**REFERENCES**

**ADDITIONAL READING**

**RISK FACTORS**

Estimated 437,180 male and 148,210 female bladder incidence

**DESCRIPTION**

**Gurdarshan S. Sandhu, MD**

**BLADDER TUMORS, BENIGN AND MALIGNANT, GENERAL**

**Epidemiology**

- **Incidence**
  - Bladder cancer: 9th most common cancer
  - Median age at diagnosis is 73
  - 3× more common in White than Black men
  - 1.5× more common in White than Black women
  - 14,880 total deaths in US in 2012 (10,510 males and 4,370 females)
  - Median age at diagnosis is 73
  - 14,880 total deaths in US in 2012 (10,510 males and 4,370 females)
  - 73,510 cases diagnosed in US in 2012 (55,600 males and 17,910 females)

**Prevalence**

- Estimated 437,180 male and 148,210 female bladder cancer cases in US as of 2012

**RISK FACTORS**

- Malignant bladder tumors
  - Smoking—main risk factor for bladder cancer
  - Risk is linearly dose and duration related, with 15–20 yr latency
  - 2nd hand smoke does not increase risk of bladder cancer formation

- Chemical exposure:
  - Especially aromatic dyes and amines
  - High-risk industries include textiles, aluminum, dye, leather, foundries, and rubber workers
  - Pelvic irradiation
  - Latency is 15–30 yr
  - Increased risk in prostate and cervical cancer treated with radiation

- **Chemotherapy**
  - Cyclophosphamide has a 4–9× increased risk for bladder cancer
  - Inflammation is a risk factor for squamous cell carcinoma (SCC)
  - Bladder cancer

- **Inflammation**
  - Chronic bladder stones
  - Schistosoma hematobium infection

- Genetics
  - Neoplastic cells carry a major role
  - History in a 1st-degree increases risk 2×
  - No clear inheritance patterns
  - p53 gene on chromosome 17
  - Overexpression leads to higher rates of progression and lower rates of response to chemotherapy
  - Loss of Retinoblastoma (RB) gene on chromosome 9
  - Development of superficial tumors
  - Slow metabolizers and slow acetylators more susceptible to environmental carcinogens

- **Pathophysiology**
  - **Patterns of spread of bladder cancer**
    - Symptomatic—hematuria
    - Hematogenous—lymph, lung, bone, etc.
    - Direct extension—prostate, urethra, uterus

- **ASSOCIATED CONDITIONS**
  - **None**

- **Diagnosis**
  - **General Prevention**
    - Smoking cessation
    - Antioxidants including vitamins A, C and E, and selenium
    - Mediterranean diet: Lowest bladder cancer risk
    - Avoid occupational exposures

- **DIAGNOSTIC TESTS & INTERPRETATION**
  - Urinalysis (for red blood cells and culture)
  - Urine cytology
  - More sensitive in high-grade disease and carcinoma in situ (90%)
  - Flow cytometry
  - Measures DNA content of cells to quantitate aneuploid cell populations
  - Other urine markers are commercially available (eg, BTA Stat, NMP 22, BladderChek), and have better sensitivities but worse specificities than cytology

- **Imaging**
  - Upper tract evaluation can be done with intravenous urography, retrograde urography, computerized tomography (CT), or magnetic resonance imaging
  - Metastatic evaluation includes chest imaging and bone scan

- **Diagnostic Procedures/Surgery**
  - Cystoscopy with bladder tumor resection or biopsy
  - Fluorescence cystoscopy may increase detection of carcinoma in situ or additional lesions

- **Pathologic Findings**
  - **Benign lesions**
    - Nonneoplastic adenoma: Metaplastic response to chronic inflammation
    - Von Brunn nests: Benign urothelial cells within the lamina propria
  - Squamous metaplasia: Common in women (40%)
  - Cystitis cystica: Central cystic degeneration of Von Brunn nests
  - Basaloid cysts
  - Malignant tumors
  - The primary tumor is urothelial—a single carcinoma

- **Associated Genes and Proteins**
  - Loss of Retinoblastoma (Rb) gene on chromosome 9
  - Inflammation is a risk factor for squamous cell carcinoma
  - Loss of Retinoblastoma (Rb) gene on chromosome 9
  - Inflammation is a risk factor for squamous cell carcinoma

- **Patterns of spread of bladder cancer**
  - Local extension—urothelial and smooth muscle
  - Lymphatic—lymph nodes, liver, bone, lung
  - Hematogenous—to liver, lung, bone, etc.

- **DIFFERENTIAL DIAGNOSIS**
  - Bladder wall mass: See “Pathologic findings”
  - Benign cystic lesions: Urinary calculi, interstitial cystitis, bladder cancer, chronic prostatitis

- **Diagnosis**
  - **Pathologic Findings**
    - **Benign lesions**
      - Nonneoplastic adenoma: Metaplastic response to chronic inflammation
      - Von Brunn nests: Benign urothelial cells within the lamina propria
    - Squamous metaplasia: Common in women (40%)
      - Cystitis cystica: Central cystic degeneration of Von Brunn nests
      - Basaloid cysts
      - Malignant tumors
      - The primary tumor is urothelial—a single carcinoma

- **Associated Genes and Proteins**
  - Loss of Retinoblastoma (Rb) gene on chromosome 9
  - Inflammation is a risk factor for squamous cell carcinoma
  - Loss of Retinoblastoma (Rb) gene on chromosome 9
  - Inflammation is a risk factor for squamous cell carcinoma

- **Patterns of spread of bladder cancer**
  - Local extension—urothelial and smooth muscle
  - Lymphatic—lymph nodes, liver, bone, lung
  - Hematogenous—to liver, lung, bone, etc.

- **DIFFERENTIAL DIAGNOSIS**
  - Bladder wall mass: See “Pathologic findings”
  - Benign cystic lesions: Urinary calculi, interstitial cystitis, bladder cancer, chronic prostatitis
SURGERY/OTHER PROCEDURES

TURBT
- Diagnostic: Consider repeat resection for T1 disease
- Therapeutic for non-muscle invasive disease
- Partial cystectomy
- For selected patients with unfavorable disease, unusual tumors, and tumors in diverticula
- Radical cystectomy
- For muscle invasive disease
- Consider for recurrent high-grade superficial disease

ADDITIONAL TREATMENT

Radiation Therapy
- Can be used in bladder sparing protocol
- Internal beam radiotherapy combined with chemotherapy to improve outcomes
- 5-y overall survival ~50%

Additional Therapies

- Cisplatin-based therapy is 1st line for small cell carcinoma
- Neoadjuvant chemotherapy for locally advanced disease prior to cystectomy
- Chemotherapy for metastatic disease with other gemcitabine, vinblastine, docetaxel and cisplatin, or gemcitabine and cisplatin

Complementary & Alternative Therapies

- Phototherapy: No long-term data
- Laser therapy
- Vitamins (6)

- Increased carotene intake, including beta-carotene, alpha-carotene and lycopene, is associated with decreased bladder cancer mortality associated with a decreased risk of bladder cancer
- Megadose multivitamins A, B6, C, and E plus zinc may decrease bladder tumor recurrence in patients receiving BCG immunotherapy
- Increased carotene intake, including beta-carotene, alpha carotene and lycopene, is associated with decreased bladder cancer risk

ONGOING CARE

PROGNOSIS

- Progression and recurrence depend upon grade, stage, size, the presence of CIS, multifocality, and frequency of prior recurrences.

COMPLICATIONS

- Bladder perforation from TURBT
- Disease progression and metastases
- Hematuria
- Urinary obstruction
- UTI or sepsis

FOLLOW-UP

Patient Monitoring
- History and physical, urinalysis, cystoscopy, and urine cytology every 3 mo for 2 yr, then every 6 mo to 2–3 yr, then once a year.
- Periodic upper tract imaging for high-risk patients

Patient Resources

- BCAN http://www.bcancer.org/bladder-cancer/support-group/

CODES

ICD9
- 188.9 Malignant neoplasm of bladder, part unspecified
- 223.3 Benign neoplasm of bladder
- 295.7 Neoplasm of uncertain behavior of bladder

ICD10
- C99.9 Malignant neoplasm of bladder, unspecified
- D40.3 Benign neoplasm of bladder
- D41.4 Neoplasm of uncertain behavior of bladder

CLINICAL/SURGICAL PEARLS

- Painless gross hematuria must be investigated to rule out bladder cancer.
- Smoking is the most common risk factor for bladder cancer.
- TURBT with biopsy is mandatory for diagnosis and staging of all bladder tumors.
BOWEN DISEASE AND ERYTHROPLASIA OF QUEYRAT

Justin D. Ellett, MD, PhD
S. Walker Nickles, MD

DESCRIPTION
Bowen disease is squamous cell carcinoma in situ (CIS) of the foreskin-bearing epithelium of the shaft and scrotum.

Erythroplasia of Queyrat (EQ) is squamous cell carcinoma in situ (CIS) arising within the preputial mucocutaneous (mucosal) epithelium of the glans penis or inner side of the foreskin. 80–90% of cases are seen in uncircumcised men.

PREVALENCE
Most often occurs in Caucasian males
Mostly in uncircumcised men
Majority in men ages 50–70, but described in adult males of all ages

INCIDENCE
Coinfection of HPV type 8 and carcinogenic genital smegma though to be carcinogenic

EPIDEMIOLOGY
Incidence
Penile cancer occurs in 1% of all malignancies in men, and EQ and BE are a fraction of these

RISK FACTORS
Relative risk factors:
HPV types (16, 18, 39, 51) have been reported
Smegma thought to be carcinogenic
Phimosis present in 75% of cases
– Arsenic exposure from well-water and other sources
– Immunosuppression from HIV/AIDS
– Therapeutic immunosuppression for organ transplants
– Infections from HPV/AIDS
– Acetic exposure from well water and other sources
– Chronic injury and inflammation from poor hygiene, urine, smegma
– Radiation
– Chronic dermatoses
– Thermal injury
– Ionizing radiation
– Arsenic exposure
– Lichen sclerosis of the glans penis
– Relationship to other structures (submucosal, corpora spongiosa and/or cavernosa, urethra)

PATHOPHYSIOLOGY
Carcinogenesis results from:
– Chronic injury and inflammation from poor hygiene, urine, smegma
– Radiation
– Exposure to chemical carcinogens, such as arsenic or smoking
– HPV infection
– Decreased immune surveillance due to HIV/AIDS or medical immunosuppression

ASSOCIATED CONDITIONS
– Progression to invasive SCC in 5–30% of cases; more likely with EQ
– Lichen sclerosis, balanitis xerotica obliterans (BXO)

GENERAL PREVENTION
– Circumcision
– Daily genital hygiene by retraction of foreskin and cleansing
– Elimination of risk for HPV infection
– Early detection of lesions
– Treatment of phimosis

DIAGNOSIS

HISTORY
– Age: Median age 50
– Sexual promiscuity (increases risk for HPV infection)
– History of phimosis or difficulty retracting foreskin
– History of nonhealing wounds, pruritus, bleeding, discharge
– History of exposure to ionizing radiation or arsenic
– History of immunosuppression for organ transplants
– Sexual promiscuity
– Age: Median age 50
– Recent history of HPV infection
– Presence of ulceration increases likelihood of invasive SCC
– Presence of ulceration increases likelihood of invasive SCC
– Examination of inguinal nodes
– Important factors to assess:
– Diameter of lesion
– Location
– Number of lesions
– Histology (papillary, nodular, verrucous, or flat)
– Relationship to other structures (submucosal, corpora spongiosa and/or cavernosa, urethra)

PHYSICAL EXAM
– Solitary or multiple nontender erythematous plaques
– BD: Scaly, verrucoid plaque on shaft
– EQ: Velvety, smooth, shiny on glans
– BD: Usually at base of glans and penile shaft
– EQ: Usually on glans
– BD: Pearly, skin-toned papule or plaque, often with overlying telangiectasias
– EQ: Usually associated with lesions at other sites
– BD: Usually in uncircumcised men
– EQ: Majority in men ages 50–70
– BD: Scaly, verrucoid plaque on shaft

PATHOLOGY
Definitive diagnosis may only be made by biopsy

DIAGNOSTIC TESTS & INTERPRETATION
Lab
– Testing for carcinogenic HPV types

Imaging
– Imaging only indicated in instances of clinical suspicion of invasion, and would include MRI or ultrasound

DIFFERENTIAL DIAGNOSIS (1)
– Bowenoid papulosis
– Invasive SCC
– Benign course, but histologically similar except abnormal keratinocytes are spread discontinuously throughout epidermis
– Early invasion should be excluded via the use of multiple biopsies
– Usually spontaneously regresses

DIFFERENTIAL DIAGNOSIS (2)
– Squamous cell carcinoma
– Immunohistochemistry
– Ulceration
– Painful, coin-shaped plaques of small grouped papules on erythematous base
– Typical in younger patients (ages 25–30)
– Usually spontaneously regresses
– Usually at base of glans and penile shaft
– BD: Usually in uncircumcised men
– EQ: Majority in men ages 50–70
– BD: Scaly, verrucoid plaque on shaft
– EQ: Usually on glans
BOWEN DISEASE AND ERYTHROPLASIA OF QUEYRAT

- Balanitis circinata
  - Dry and scaling lesions of the glans in circumcised or uncircumcised males
  - Associated with Reiter’s syndrome
  - Can be moist and erythematous in uncircumcised males
- Candidal balanitis
  - Usually found in uncircumcised diabetics
  - Reddened and edematous lesions
  - Usually treated with antifungal therapy
  - In elderly, uncircumcised males
  - Usually distinguished from CIS on biopsy by band-like infiltrate of plasma cells

TREATMENT

GENERAL MEASURES (3)
Treatment based on multiple biopsy samples of adequate depth to rule out invasion

MEDICATION
First Line
- Topical therapy
  - 5-fluorouracil cream BID for 4–5 wk or
  - 5% imiquimod cream daily for 16 wk
  - Proven effective for large lesions not amenable to surgery or for recurrent lesions
  - Utilized with rubber condom to increase contact time

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Circumcision can decrease likelihood of recurrence
- With lesions on the foreskin, circumcision, or excision with 5-mm margin is adequate for local control
- Lesions on the glans are difficult to excise with this strategy when trying to preserve penis anatomy
- Ensure adequate depth of resection to rule out invasion
- Mohs micrographic surgery has been utilized to accomplish adequate excision without disfigurement
- Nd:YAG, KTP, or carbon dioxide laser ablation has been shown to be effective
  - Nd:YAG preferred due to depth of penetration

ADDITIONAL TREATMENT
Radiation Therapy
Radiation therapy can be used for patients resistant to topical treatment or who are not surgical candidates

Additional Therapies
Additional therapies include cryotherapy, cautery, and photodynamic therapy, although their effectiveness is limited

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- 5–33% of cases have been reported to transform to SCC
  - 5–10% risk in BD, 10–33% in EQ
  - Carries significant risk of death
- All therapies have recurrence rates of 20–30%

COMPLICATIONS
Progression to invasive squamous cell carcinoma

FOLLOW-UP
Patient Monitoring
- BC and EQ surveillance parallels localized, invasive SCC of the penis with clinical exam:
  - Year 1–2, every 3 mo
  - Year 3–5, every 6 mo
  - Year 5–10, every 12 mo
  - Consider re-biopsy of recurrent lesions to rule out transformation to invasive SCC

Patient Resources

- Penis, Cutaneous Lesion
- Penis, Squamous Cell Carcinoma

CODES
ICD9
233.5 Carcinoma in situ of penis

ICD10
D07.4 Carcinoma in situ of penis

CLINICAL/SURGICAL PEARLS
- BC = SCC in situ arising on the glans or inner side of the foreskin.
- BD = SCC in situ of the penile shaft or corona.
- ED = 96% of cases seen in uncircumcised men.
- Progression to invasive SCC in 5–30%.
BURNS, EXTERNAL GENITALIA AND PERINEUM

Brad Figler, MD
Hunter Wessells, MD, FACS

BASICS

DESCRIPTION
Burns to the external genitalia and perineum can damage skin, subcutaneous tissue, and surrounding organs and can be due to thermal, electrical, or chemical contact.

Thermal (most common): Includes scalding and immersion injuries, direct contact with flames or hot objects.

Electrical: Passage of an electrical current from one point to another through the body.

Chemical: Corrosive and alkali substances found in household and industrial chemicals.

EPIDEMIOLOGY

Incidence
- Genital/perineal burns are rarely isolated.
- Genitals/perineum involved in 5–13% of burns treated at major burn centers.
- Abuse or neglect in 10–15% of childhood burn injuries (higher if <2 yr of age).

RISK FACTORS
- Age: Very young (scald burns common in abused children) and very old.
- Employment: Exposure to flames or caustic substances.
- Gender: Women are less likely to experience genital or perineal burns (less exposed).

PATHOPHYSIOLOGY

Classification (1)
- 1st-degree (superficial): Epidermis
  - Superficial (involving the superficial, papillary dermis)
  - Deep (involving reticular dermis)
- 2nd-degree (partial thickness): Dermis
  - Superficial (involving the superficial, papillary dermis)
  - Deep (involving reticular dermis)
- 3rd-degree: Unilateral subcutaneous tissue
  - Typically not painful due to nerve damage
- 4th-degree: Bone and muscle
  - Can lead to compartment syndrome
  - Often fatal

ASSOCIATED CONDITIONS
- Child sexual abuse
- Sexual abuse
- Myoglobinuria (electrical burns)

GENERAL PREVENTION
- Follow occupational-specific safety precautions.
- Handle caustic chemicals with care.

DIAGNOSIS

HISTORY
- Type of burn (thermal, chemical, or electrical)
- Causative agent or heat source (e.g., flame vs. water, nonionic substance)
- Location and area involved (Rule of Ns): External genitalia and perineum usually accounts for 1% of body surface area when using “Rule of Ns.”
- Possibility of other injuries (e.g., fractures from motor vehicle accidents, shrapnel).

PHYSICAL EXAM
- Complete assessment including ABCD’s of Advanced Trauma Life Support (ATLS). Often associated with concomitant injuries or further burns.
- With electrical burns determine any other entry/exit site of current.
- Rule of Ns: Based on total body surface involved. Genitalia/perineum accounts for 1% of body area.
- Vital signs (patients with electrical burns will require cardiac monitoring for at least 24 hr).
- Neurologic exam: Evaluate for compartment syndrome, peripheral pulses.
- GU: Examine for involvement of phallic, meatus, glans, and scrotum.
- Classification:
  - 1st-degree: Characterized by erythema, white plaques, and mild pain
  - 2nd-degree: Characterized by erythema, pain, superficial blisters
  - 3rd-degree: Characterized by eschar, blistering, and absence of pain due to loss of nerve fibers

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Electrolytes: Treatment of burns generally requires large amount of fluid resuscitation.
- With electrical burns, monitor creatine kinase and urine myoglobin.

Pathologic Findings
- Zone of coagulation: Occurs at point of maximum damage. In this zone, there is irreversible tissue loss due to coagulation of the constituent problem.
- Zone of stasis: Surrounding zone of stasis is characterized by decreased tissue perfusion. The tissue in this zone is potentially salvageable. The main aim of burn resuscitation is to increase tissue perfusion here and prevent any damage from becoming irreversible. Additional insults – such as prolonged hypotension, infection, or sepsis – can cause this zone into an area of complete tissue loss.
- Zone of hyperemia: In this outermost zone, tissue perfusion is increased. The tissue here will inevitably recover unless there is severe sepsis or prolonged hypoperfusion.

DIFFERENTIAL DIAGNOSIS

Diagnosis is usually apparent based on history and examination.

ALERT
- Treat any life-threatening conditions (ABCD’s).
- IVF: Resuscitation is critical if patient has severe burns.
**Burns, External Genitalia and Perineum**

**TREATMENT**

**GENERAL MEASURES**
- Treat any life-threatening conditions (ABCD)
  - Do not attempt to cool wound as this may cause more extensive injury
- Shock may occur; IVF critical
  - >20% total body surface area (TBSA), use modified Brooke formula:
    - 2 mL/kg/TBSA
- Most chemical burns should be copiously irrigated. If agent is known use guidelines:
  - Hydrofluoric acid: Irrigate with calcium gluconate
  - Hydrochloric acid or sulfuric acid: Use bicarbonate irrigation
  - Phenol: No irrigation

**MEDICATION**

**First Line**
- Silver sulfadiazine 1%: Apply to affected area
  - Does not penetrate eschar
- Mafenide acetate (Sulfamylon) 11.1%: Penetrates eschar
- Pain control
  - Narcotics
  - Anti-inflammatories
- Fluid resuscitation
- Electrolytes as needed
- Tetanus prophylaxis
- Antibiotic prophylaxis not necessary
  - Treat specific infections as they arise.

**SURGERY/OTHER PROCEDURES (2,3)**
- Most burns, particularly in children, should be managed with conservative treatment and require no surgical intervention.
- Foley catheter or suprapubic drainage may be used, but are often not necessary.
- Mainstay of surgical treatment, if needed, is careful debridement.
- Affected areas may require skin coverage:
  - Granulation indicates acceptable graft bed
  - Split-thickness skin grafts have reliable graft take and excellent cosmesis
  - Skin grafts can be meshed or unmeshed
  - If graft bed health is questionable, can use temporary xenograft
- Wound contractures are not uncommon; treat with z-plasty
- Urethral stricture may develop; should be treated in a delayed fashion (4)
  - Catheter drainage may be required in the interim

**ONGOING CARE**

**PROGNOSIS**
- Based on degree and extent of burn
- Most burns have matured by 6–12 mo; additional reconstruction may be required at that time

**COMPLICATIONS**
- Erectile dysfunction
- Scarring/disfigurement

**FOLLOW-UP**

**Patient Monitoring**
- Follow-up as indicated

**Patient Resources**
- American Burn Association
  - www.ameriburn.org
- Phoenix Society for Burn Survivors
  - www.phoenix-society.org

**REFERENCES**

**ADDITIONAL READING**

**SEe Also** (Topic, Algorithm, Media)
- Burns, External Genitalia and Perineum Image 6
- Penis, Trauma
- Scrotum and Testicle, Trauma

**CODES**

**ICD9**
- 942.05 Burn of unspecified degree of genitalia
- 942.15 Erythema (first degree) of genitalia
- 942.25 Blisters, epidermal loss (second degree) of genitalia

**ICD10**
- T21.06XA Burn of unsp degree of male genital region, init encntr
- T21.07XA Burn of unsp degree of female genital region, init encntr
- T21.16XA Burn of first degree of male genital region, init encntr
- T21.16XB Burn of first degree of female genital region, init encntr

**CLINICAL/SURGICAL PEARLS**
- Genital/perineal burns are rarely isolated.
- Favor conservative management initially.
- Excellent functional and cosmetic results are possible with split-thickness skin grafting.
CALYCEAL DIVERTICULA
Yaniv Shilo, MD
Timothy D. Averch, MD, FACS

## BASICS

### DESCRIPTION
- Calyceal diverticula are nonsecretory, transitional cell epithelium-lined cystic cavities within the renal parenchyma.
- The cavity is usually filled retrograde from urine in the collecting system.
- Mostly unilateral.
- Most prevalent in upper calyces (70%).
- No gender nor laterality predilection.
- Bilateral in 3%.
- Sometimes called pelvicaliceal diverticula.

### EPIDEMIOLOGY

#### Incidence
- Less than 1%.

#### Prevalence
- Found in up to 0.45% of routine intravenous pyelogram studies.

### RISK FACTORS

#### Genetics
- N/A.

### PATHOPHYSIOLOGY
- Congenital in origin due to failure of regression of ureteric bud.
- Urine enters diverticulum passively via narrow communication with collecting system.
- Urine trapped in diverticulum predisposes to infection and stone formation.

### ASSOCIATED CONDITIONS
- Flank pain.
- Calyceal calculi (9–50%).
- Recurrent urinary tract infection (UTI).
- Hematuria.

### GENERAL PREVENTION
- N/A.

## DIAGNOSIS

### HISTORY
- Mostly incidental finding on imaging.
- Flank pain.
- Microhematuria or macrohematuria.
- Recurrent UTI.

### PHYSICAL EXAM
- Usually not suggestive.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab
- Urinalysis:
  - Microhematuria and pyuria.
- Urine culture:
  - Bacterial persistence.

#### Imaging
- Abdominal x-ray (KUB):
  - May demonstrate characteristic radiopaque "milk of calcium," which appears as a half moon or meniscus-shaped calcification.
  - Milk of calcium should change its location when changing positioning from erect to lateral decubitus.
- Case reports of confusion as being diagnosed as rib metastasis.
- Ultrasound (US):
  - Provide diagnosis in up to 90% of the cases.
- CT urography (CTU):
  - Delayed imaging is critical to demonstrate contrast medium within an apparent cystic mass.

### Diagnostic Procedures/Surgery

- Intravenous pyelography (IVP):
  - Detected imaging demonstrates the diverticulum, as it fills retrogradely from its connection to the renal pelvis or calyx.
- CT urography (CTU):
  - Delayed imaging is critical to demonstrate contrast medium within an apparent cystic mass.
- Retrograde pyelogram:
  - Allows greater distension of the collecting system than can be attained with IVP.
  - Delineating anatomy and assist in planning the appropriate treatment approach.

## Pathologic Findings
- Lined by nonsecretory transitional epithelium.
- Retrograde reflux of urine from the calyx via the diverticular neck can cause stasis with stones in calyceal diverticula in up to 50% of cases.

## DIFFERENTIAL DIAGNOSIS
- Calcified tumor.
- Complicated renal cyst.
- Kidney abscess.
- Nephrolithiasis.

## TREATMENT

### GENERAL MEASURES
- In case of uncomplicated, asymptomatic calyceal diverticulum treatment can be conservative with no further imaging follow-up.
- Indications for therapy include pain, recurrent infection, increased calculus growth, hematuria or large size that compresses or progressively damages contiguous renal parenchyma.

### MEDICATION

#### First Line
- Antibiotic treatment can be used for recurrent UTIs; otherwise no specific role.

#### Second Line
- N/A.

### SURGERY/OTHER PROCEDURES

- Shock wave lithotripsy (SWL):
  - May be suitable for calyceal diverticulum with small calculi and wide infundibulum (1).
  - Can resolve flank pain.
- Ureteroscopy (URS):
  - Most suitable as initial treatment for calculi <1.5 cm located in the middle or upper pole diverticulum and specifically in the anterior aspect.
  - Involves mechanical dilatation of the diverticular neck and removal of calculus if present.

- Abdomopacification of diverticular cavity is not a common practice.
CALYCEAL DIVERTICULA

**Percutaneous nephrolithotomy (PCNL):**
- Considered to be the definitive surgical treatment specifically for diverticula containing stone burden >1.5 cm in the posterior aspect.
- Challenging when only thin layer of parenchyma surrounding the diverticula or located anteriorly.
- Requires direct access to diverticulum and infundibulum widening.
- Ablation of the calyceal diverticulum cavity is recommended (2).

**Laparoscopic nephrolithotomy (LAP):**
- May be advantageous in cases of anterior diverticula, diverticula covered with thin layer, diverticula containing large calculi or large diverticula (3).
- Includes unroofing of the diverticulum and calculi removal if present.
- Ablation of the remaining cavity and neck.

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- N/A

**Complementary & Alternative Therapies**
- N/A

**ONGOING CARE**

**PROGNOSIS**
- Stone-free rate is relatively low (up to 60%).
- URS: Stone-free and symptom-free rates can be high when infundibulum is identified.
- PCNL: Excellent stone-free and symptom-free rates (over 80%).
- LAP: Initial results show high stone-free rate and diverticular ablation.

**COMPLICATIONS**
- Calyceal diverticula:
  - Secondary infection
  - Chronic pain with stones
  - Compression of surrounding tissue
  - Bleeding
  - Infection
  - Subcapsular or perinephric hematoma
- URS:
  - Bleeding
  - Thermal injury to ureteral wall or renal parenchyma
  - Urinary extravasation
  - Nephrothorax
  - Collecting system perforation

**FOLLOW-UP**

**Patient Monitoring**
- Radiographic imaging with either CTU, IVP, or kidney US should be done 6–8 wk postoperatively.
- Patients with calculi contained in diverticulum may need metabolic evaluation as these patients tend to have metabolic abnormalities similar to patients with nephrolithiasis (1).

**Patient Resources**
- N/A

**REFERENCES**

**ADDITIONAL READING**

**See Also** (Topic, Algorithm, Media)
- Calcifications, Renal
- Calyceal Diverticula Image
- Nephrocalcinosis
- Urolithiasis, Adult, General considerations
- Urolithiasis, Renal

**CODES**
- ICD9:
  - 592.0 Calculus of kidney
  - 593.89 Other specified disorders of kidney and ureter
  - 753.8 Other specified congenital malformations of kidney
- ICD10:
  - N20.0 Calculus of kidney
  - N28.89 Other specified disorders of kidney and ureter
  - Q63.8 Other specified congenital malformations of kidney

**CLINICAL/SURGICAL PEARLS**
- Usually located on upper calyces.
- Associate disorders include—calyceal calculus, recurrent UTI, and flank pain.
- URS is suitable for anterior midpole or upper diverticula with calculi <1.5 cm.
- PCNL is the treatment of choice in general for calyceal diverticula and specifically for posterior diverticula with thick layer of parenchyma surrounding with calculi >1.5 cm.
- Growing evidence for the effectiveness of LAP approach in cases of anterior diverticula, diverticula covered with thin layer, diverticulum containing large calculi or large diverticulum.
CATHETERIZABLE STOMA PROBLEMS
Zachary L. Smith, MD  S. Bruce Malkowicz, MD, FACS

PATHOPHYSIOLOGY
- Stomal stenosis can be attributed to infrequent catheterization, scar formation, ischemia secondary to compromised vascular supply to catheterizable channel, or a remnant-free mucocutaneous anastomosis.
- Difficulty catheterizing the CS channel can be attributed to angulation of a mobile and/or redundant channel.
- Significant weight loss or gain
- Improper creation of continence mechanism
- Incomplete detubularization or augmentation of the urinary reservoir can lead to incontinence secondary to low compliance and small reservoir capacity.
- Pouchitis (lower urinary tract infection) can cause temporary failure of the continence mechanism because of the hypercontractility of the bowel segment; can be caused by inflammation of the mucosa.

ASSOCIATED CONDITIONS
- Urologic, gynecologic, and colorectal malignancies
- Spinal dysraphisms
- Traumatic spinal cord injuries
- Incomplete detubularization or augmentation of the urinary reservoir can lead to incontinence secondary to low compliance and small reservoir capacity.
- Malignancy
- Incontinence (urinary vs. fecal)

DIAGNOSIS

HISTORY
- Date of surgery
- Indication for CS
- Incontinence (urinary vs. fecal)
- Malignancy
- Attempt to obtain operative reports
- Type of bowel utilized
- History of CS complications
- Catheterization details:
  - Typical catheterization regimen
  - Type and size of catheter used
  - Technique utilized (direction, amount of pressure, etc.)
- Normal catheterization volumes
- Time of last normal catheterization
- Character of urine at the time of last successful catheterization (color, odor, presence of debris, etc.)

PHYSICAL EXAM
- Vital signs may reveal tachycardia, hypotension, and fever in patients with peritonitis secondary to perforation of the catheterizable channel or urinary reservoir.
- Abdominal exam evaluating signs of peritonitis
- Inspection of the stoma, evaluating for:
  - Tenesmus
  - Mucosal ischemia
  - Abdominal wall deformity suggestive of parastomal hernia
  - Catheterization of CS to:
    - Evaluate patency of stoma
    - Determine capacity of urinary reservoir
    - Evaluate continence mechanism
    - Obtain urine sample
    - Inspect contrast for imaging.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Serum electrolytes:
  - Elevated serum creatinine may be noted in patients with urinary retention from the inability to catheterize.
  - Several metabolic abnormalities may be present in patients with urinary reservoirs, depending on bowel segment utilized.
    - Stomach: Hypochloremic, hypokalemic alkalosis
    - Jejunum: Hyponatremic, hypochloremic, hyperkalemic acidosis
    - Ileum: Hypochloremic, hyperkalemic acidosis
    - Colon: Hyperchloremic acidosis
  - CBC:
    - Leukocytosis suggestive of infection
    - Blood and urine cultures in patients presenting with abdominal pain and fever

Imaging
- Contrast study of catheterizable channel and urinary reservoir to evaluate for perforation
- Cross-sectional imaging of the kidneys assessing for the presence of hydronephrosis

ALERT
- Have a low threshold for obtaining a cross-sectional imaging study (CT/MRI) with contrast when a perforation of the CS or urinary reservoir is suspected, especially in patients with neurologic deficits.
DIFFERENTIAL DIAGNOSIS
- Parastomal hernia:
- Stomal stenosis:
- Fistula:
- Pouchitis:
- Perforation of CS conduit or urinary reservoir
- Inability to catheterize secondary to false passage or redundancy of CS channel:
- Fistula:
  - Electrolyte revision
  - Inability to catheterize secondary to false passage or redundancy of CS channel:
  - Electrolyte revision
  - Occasionally, minor false passages can be treated with an indwelling catheter for a short period to allow healing of channel.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Stomal stenosis:
  - Routine catheterization schedule
  - Dilatation of stenosis
  - Local excision
  - Antibiotics
  - Catheterizable channels and the timing of their catheterization

Ongoing Care

Study following stoma revisions for stoma ranges from 80–95% (1). Complications

Follow-Up

Maintenance of routine catheterization schedule

Patient Monitoring

- Additional follow-up with enterostomal therapist

Patient Resources

- National Ostomy Association of America, Inc.
- Bladder Cancer Advocacy Network: www.bcan.org
- United Ostomy Associations of America, Inc.: www.ostomy.org

CODES

ICD-9
- 598.82: Mechanical complication of cystostomy
- 598.83 Other complication of cystostomy
- V55.5: Attention to cystostomy

ICD-10
- N99.512: Cystostomy malfunction
- N99.518 Other cystostomy complication
- Z43.5: Encounter for attention to cystostomy

CLINICAL/SURGICAL PEARLS

- Catheterizable stoma are used for varying reasons throughout one’s life. Benign/neurogenic causes most common in children, malignant causes most common in adults.
- Stomal stenosis is by far the most common complication of catheterizable stomas.
- Surgical revision is often required for most catheterizable stoma complications.
- Good technique and catheterizable stoma maintenance with a routine catheterization schedule can prevent most complications.
CHordee
Jennifer A. Hagerty, DO

### BASICS

**DESCRIPTION**
- Chordee is ventral penile curvature that occurs with or without hypospadias.
  - Epispadias can occur with dorsal curvature.
  - Lateral curvature also can occur with or without hypospadias.

**EPIDEMIOLOGY**

**Incidence**
The incidence of chordee is unknown.

**Prevalence**
- 44% of fetuses through the 2nd trimester suggesting chordee is a normal part of development (1A).
- Hypospadias occurs in 1 of 250 live births (3A).
  - Chordee is identified in 1/3 of these patients (3A).

**RISK FACTORS**
- Congenital
- Prior penile surgery
- Trauma

**Genetics**
- Found in syndromes associated with hypospadias.
- Chromosomal abnormalities found in 22% of individuals with severe hypospadias associated with undescended testicles.
- 14% of hypospadias in siblings.
- 8% incidence in offspring.

**PATHOPHYSIOLOGY**
- Chordee could be considered an arrest of normal embryologic development.
- Different proposed etiologies for chordee without hypospadias (2,4):
  - Class I: Results when corpus spongiosum, dartos, and Buck fasciae are deficient over the involved portion of the urethra, urethra is just below the skin, and the dense fibrous tissue beneath the urethra is responsible for the chordee.
  - Class II: Spongiosum is normal while the dartos and Buck fasciae are dysgenetic.
  - Class III: Only the dartos fascia is deficient.
  - Class IV: Corporeal disproportion.

**ASSOCIATED CONDITIONS**
- Hypospadias
- Epispadias
- Penile torsion
- Cryptorchidism
- Disorders of sexual development

**GENERAL PREVENTION**
None known

### DIAGNOSIS

**HISTORY**
- Visualized curvature of the penis with an erection.
- Presence of hypospadias.

**PHYSICAL EXAM**
- Observe the individual's erection if possible.
  - Possible coexisting findings:
    - Hypospadias or epispadias
    - Incomplete foreskin ventrally
    - Penoscrotal webbing
    - Penile torsion
    - Hypoplasia of the ventral shaft skin
    - Cryptorchidism

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Routine lab testing not typically indicated.
- Chromosomal testing and/or biochemical testing in the individual with a suspected syndrome or disorder of sexual differentiation.

**Imaging**
- Renal and bladder ultrasound routinely recommended only in individuals with:
  - Severe hypospadias.
  - Hypospadias associated with other organ system anomalies.

**Diagnostic Procedures/Surgery**
- Intraoperative artificial erection test at the time of repair.
- Inflation of injectable saline into the corpora with a tourniquet at the base of the penis.

**Pathologic Findings**
N/A

### DIFFERENTIAL DIAGNOSIS
- Disorder of sex development
- Epispadias
- Hypospadias
- Normal penile variant
- Penile torsion

### TREATMENT

**GENERAL MEASURES**
- Chordee repair is the standard approach.

**MEDICATION**
- First Line: None usually indicated specifically for chordee.
- Second Line: N/A

**SURGERY/OTHER PROCEDURES**
- Specific surgery dependent on the associated conditions and the severity of the curvature.
- Performed typically after 6 mo of age.
  - General points:
    - Following penile skin release, induce artificial erection. This should be repeated to confirm correction.
    - Chordee without hypospadias often can be corrected by penile degloving with excision of the fibrous tissue superficial to Buck fascia.
    - More moderate chordee requires simple plication and/or excision of ellipses from the site of maximum curvature.
    - In the most severe cases, often associated with hypospadias, the urethra may be shortened and need to be transected.
Chordee secondary to corporeal disproportion involves incising the tunica albuginea on the ventral surface of the penis, transversely over the point of maximal curvature; then covering the defect with either a full-thickness, tunica vaginalis or single ply small intestinal submucosal (SIS) graft.

It is critical to identify and preserve the neurovascular bundles during dissection and plication.

Skin flaps may be required for penile skin coverage after correction of the chordee.

**ADDITIONAL TREATMENT**

**Radiation Therapy**

N/A

**Additional Therapies**

N/A

**Complementary & Alternative Therapies**

N/A

**ONGOING CARE**

**PROGNOSIS**

- Excellent prognosis postoperatively with a low complication rate
- There may be progression of chordee after puberty

**COMPLICATIONS**

Recurrence of chordee

**FOLLOW-UP**

**Patient Monitoring**

- Postoperative check-up within several weeks after surgery
- Consider follow-up after puberty

**PATIENT RESOURCES**

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD9**

- 607.89 Other specified disorders of penis
- 752.61 Hypospadias

CHRONIC KIDNEY DISEASE, ADULT (RENAL FAILURE, CHRONIC)
Shawn G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

PATHOPHYSIOLOGY
Pathologic Findings
- Renal biopsy
- Nondiabetic kidney disease
- Nephrotic syndrome
- Acute/nephritic syndrome
- Acute/rapid progressive kidney disease
- Urologic evaluation if gross or microscopic hematuria
- Cytoscopy
- Upper tract imaging
- Angiography (CT or MR angiogram)

Differential Diagnosis
- Renal biopsy/kidney
- Nondiabetic kidney disease
- Nephrotic syndrome
- Acute/nephritic syndrome
- Acute/rapid progressive kidney disease
- May also be seen on nephrectomy/partial nephrectomy specimens

Diagnostic Procedures/Surgery
- Renal biopsy
- Nondiabetic kidney disease
- Nephrotic syndrome
- Acute/nephritic syndrome
- Acute/rapid progressive kidney disease
- Urologic evaluation if gross or microscopic hematuria
- Cytoscopy
- Upper tract imaging
- Angiography (CT or MR angiogram)

Diagnosis
- Silent, asymptomatic until late stages
- Evaluate for symptoms of associated conditions/risk factors
- May be seen on nephrectomy/partial nephrectomy specimens

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Chemistry
- Elevated creatinine
- Elevated blood urea nitrogen
- Hyperkalemia
- Acidosis
- Hyperphosphatemia
- Uremia with microcytosis
- Hemosiderin
- Casts: RBC (glomerulonephritis), WBC (interstitial nephritis)

Genetics
- Complex phenotype impacted by various genetic factors, with additional environmental factors
- CYP24A1 gene involved in renal bone reabsorption and is associated with increased risk in African Americans (6)
- APOL1 associated with focal segmental glomerulosclerosis and hypertension associated EDS (1)

Risk Factors
- Diabetes
- Hypertension
- Cardiovascular disease
- Family history
- Age >60
- Urinary tract obstruction
- Urinary calculi
- Nephrotic drugs
- Obesity
- Neplasia
- Loss of kidney mass
- Race
- African American, American Indian, Hispanic, Asian, or Pacific Islander

EPIDEMIOLOGY
Incidence
- 5% prevalence in noninstitutionalized adults
- Corresponds to 20 million people
- 398,000 treated by dialysis in 2000, expected to increase to 2 million people by 2030
- Prevalence in US population
- Stage 1: 1.1%
- Stage 2: 2.2%
- Stage 3: 7.7%
- Stage 4/5: 0.3% [1]

Associated Conditions
See risk factors

GFR (mL/min/1.73 m²) for:
- Stage 1: Kidney damage with normal renal function
- Stage 2: Mild renal dysfunction
- Stage 3: Moderate renal dysfunction
- Stage 4: Severe renal dysfunction
- Stage 5: Kidney failure (GFR < 15 or dialysis required)

Incidence
- Stage 1 or 2 CKD progress to more advanced stages at 0.5% per year
- Stage 1 or 2 CKD progress to end-stage renal disease at 1.5% per year

Hypertension
- African American, American Indian, Hispanic, Asian, or Pacific Islander

Description
- Complex phenotype impacted by various genetic factors, with additional environmental factors
- CYP24A1 gene involved in renal bone reabsorption and is associated with increased risk in African Americans
- APOL1 associated with focal segmental glomerulosclerosis and hypertension associated EDS

PHYSICAL EXAM
- Physical exam findings uncommon until late stages
- Differentiate from acute kidney disease based on duration and underlying etiology
- Acute kidney injury
- Acute nephritis
- Acute/nephritic syndrome
- Nondiabetic kidney disease
- Nephrotic syndrome
- Acute/rapid progressive kidney disease
- May also be seen on nephrectomy/partial nephrectomy specimens

PATHOBASIS
- Heterogenous condition with various causes
- Diabetic kidney disease
- Nephrotic kidney disease
- Glomerular disease
- Vascular disease
- Tubulointerstitial disease
- Cystic disease (polycystic kidney disease)
- Transplant nephropathy
- Acute rejection
- Chronic rejection
- Calcineurin toxicity
- Glomerulonephropathy

Associated Conditions
See risk factors

Screening and treatment of associated risk factors

Risk Factors
- Diabetes
- Hypertension
- Cardiovascular disease
- Family history
- Obesity
- Neplasia
- Loss of kidney mass
- Race
- African American, American Indian, Hispanic, Asian, or Pacific Islander

84
CHRONIC KIDNEY DISEASE, ADULT (RENAL FAILURE, CHRONIC)

TREATMENT
GENERAL MEASURES
- Use CKD staging to guide management (ie, risk for progression and complications of CKD). See Table II: “Chronic Kidney Disease (CKD).”
- Goal is reduction of morbidity and mortality from associated comorbidities.
- Patient more likely to die of cardiovascular disease than progress to dialysis (3).
- Blood glucose control (HbA1c <7).
- Treatment of proteinuria and hypertension.
- Treatment of dyslipidemia to prevent cardiovascular events.
- Addressing alterations in bone metabolism (hyperparathyroidism, Vitamin D deficiency).
- Prevention of contrast-induced nephropathy (patient at risk if GFR <60).
- Avoidance of herbal remedies which may have nephrotoxic effects.

ADDITIONAL TREATMENT
Surgery/Other Procedures
- Dialysis access as appropriate (vascular or peritoneal).
- Renal transplantation.

Procedures
- Skin biopsy (biopsy) if appropriate.
- Peritoneal dialysis.
- Arteriovenous fistula.
- Arteriovenous graft.

MEDICATION
First Line
- ACE inhibitors (ACE-I) (captopril, enalapril, ramipril, others).
- Angiotensin II receptor blockers (ARBs) (losartan, olmesartan, telmisartan others).
- Statin therapy.
- Statin therapy.
- Statin therapy.
- Statin therapy.

Second Line
- Thyroid hormone, erythropoietin, anabolic agents, or erythropoiesis-stimulating agents.
- Calcium and vitamin D supplements.
- Phosphorus binders.
- Paricalcitol.
- Denosumab.

Therapies
- Calcium and vitamin D supplements.
- Phosphorus binders.
- Paricalcitol.
- Denosumab.

Clotting
- Factor replacement therapy.
- Anticoagulants.

SURGERY/OTHER PROCEDURES
- Skin biopsy (biopsy) if appropriate.
- Peritoneal dialysis.
- Arteriovenous fistula.
- Arteriovenous graft.

PROGNOSIS
- Degree of proteinuria correlates with risk of progression.

FOLLOW-UP
Patient Monitoring
- Stage 1–2
  - Monitor GFR, proteinuria, and blood pressure.
  - Clinical abnormalities rare at this stage but patients must be monitored for progression.
  - Monitor heart rate and diastolic blood pressure in diabetics.
  - Renal function evaluation every 3 mo.
  - Serum electrolytes, and hemoglobin.

- Stage 3
  - MNT GFR, proteinuria, blood pressure, HbA1c, serum electrolytes, and hemoglobin.
  - Elevation of phosphorus, potassium, and anemia may be seen.

- Stage 4
  - Monitor GFR, proteinuria, blood pressure, HbA1c, serum electrolytes, and hemoglobin.
  - Significant electrolyte abnormalities common; monthly follow-up with nephrology.

- Stage 5
  - Severe electrolyte abnormalities and anemia present; ongoing follow-up with renal replacement therapy.

Patient Resources
- National Kidney Foundation.
- Kidney.org/patients.

ONGOING CARE
PROGNOSIS
- Variable depending on stage, patient risk factors, and management of comorbidities.
- 10–100× increased risk of cardiovascular complications in ESRD patients.
- 13–28% 1 yr mortality in patients initiating hemodialysis (5).

COMPLICATIONS
- CKD patients at increased risk of progression.
- Cardiovascular disease, hypertension, anemia, disorders of mineral metabolism, and death.

PEARLS
- Degree of proteinuria correlates with risk of progression.

CLINICAL/SURGICAL PERILS
- Degree of proteinuria predicts progression.

REFERENCES

ADDITIONAL READING
- See Also (Topic, Algorithm, Media).
- See Table in Section II “Chronic Kidney Disease (CKD).”
**CHRONIC KIDNEY DISEASE, PEDIATRIC (RENAL FAILURE, CHRONIC)**

**Timothy E. Bunchman, MD**

**Megan M. Lo, MD**

**PATHOPHYSIOLOGY**

- In interstitial renal diseases, the degree of CKD is related to the amount of renal mass. In those patients who were born with small kidneys or have associated obstructive uropathy (POCUS, UPJ, megaloureteric syndrome) often will have early progressive loss of renal function.
- Glomerular-based renal disease is more common in the school-age and greater population.
- The clinical presentation of glomerulonephritis is associated with edema, hypertension, as well as blood and protein in the urine, most need a renal biopsy.

**ASSOCIATED CONDITIONS**

- Hypertension
- Short stature

**GENERAL PREVENTION**

- In CKD associated with congenital renal disease there is no true prevention.
- In TID, the presence of polyuria, polydipsia, and congenital diseases and/or syndromes.
- Prevention from a glomerular-based renal disease is limited as these are usually related to autoimmune diseases. Therefore, the general prevention in all areas of CKD is prevention of complications of CKD.

**DIAGNOSIS**

- In glomerular-based renal disease the history is associated with grossly bloody urine, hematuria, proteinuria, hypertension, and edema. Tissue pathology is generally needed for diagnosis.
- In the review of systems, the findings of polyuria, polydipsia, and exclusion of diabetes is important.
- Family history is important in certain renal disease, specifically in the area of the familial renal disease such as IgA nephropathy, Alport, polycystic kidney disease, and rarely benign familial hematuria.
- In addition, eliciting a history of reflux and congenital renal abnormalities within the family is important.
- Further, a family history of dialysis or transplantation or unexplained hypertension earlier in life may be important.
- In the classic Alport syndrome (a male predominant disease) there is an association with high-frequency hearing loss, often in the 2nd or 3rd decade of life.

**PHYSICAL EXAM**

- Often these children have a bivirg exam

- In TID, the blood pressure and poor growth are important.
- In CGD, kids often have hypertension.
- Can have associated edema, anorexia, and cardiovascular abnormalities.

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Lab**
  - Basic metabolic panel, renal function testing
  - Regardless of the etiology of CKD, at levels of CKD 3 or greater (roughly 50% kidney function), one can have:
    - Metabolic acidosis (low CO2)
    - Abnormal parathyroid activity
    - Low calcium, elevated phosphorus, and elevated PTH
    - Anemia that is usually related to a combination of iron deficiency, as well as the lack of natural erythropoiesis.
  - C3-C4 complement
  - Decreased in some glomerulonephritis and lupus nephritis.
  - Urinalysis:
    - In TID, the urine is usually benign with inability to concentrate the urine regardless of the time of day.
    - In CGD, often these patients can have blood and protein and red cell casts.
    - Urine protein: Creatinine ratio, usually 24 hr urine for protein.

- **Imaging**
  - In TID if the renal imaging is important.
    - Often these patients can have normal to small looking kidneys seen on ultrasound. The echogenic texture will be important. Further, some degree of obstructive uropathy may be seen.
    - Voiding cystourethrogram may be indicated
    - In those patients who have obstructive uropathy, either a UBT or IVU, a diuretic renal scan or MAG3 scan may be important.
  
  - In CGD, renal imaging may show nephromegaly. Otherwise, ultrasound will be non-specific.

**Diagnosis Procedure/Surgery**

- In glomerular-based renal diseases renal biopsy is often required.
- Indication for biopsy in patients with CGD is a non-complementable glomerulonephritis or a persistant low C3, and a low C4.
- Other indications: Glomerulonephritis associated with an elevated anti-dsDNA (lupus), hemoptysis with associated renal glomerulonephritis (pulmonary, renal disease), and in patients with persistent low C3 without normalization after 12 wk, which would be postinfectious glomerulonephritis. (Historically poststreptococcal glomerulonephritis).

**Pathologic Findings**

- Histologic analysis in interstitial renal disease is not essential.
- In glomerular-based renal diseases, renal biopsy is often required.
- Depending on underlying cause, the pathologic findings are vastly different on H&E, immunofluorescence, and electron microscopy.
DIFFERENTIAL DIAGNOSIS
• As mentioned for TID, polycystic kidney disease can also be associated with diabetes, which is an easy diagnosis to exclude based on urinalysis and blood work.
• Differential diagnosis of CKD is limited to underlying disease—Congenital renal anomalies: Obstructive uropathy, renal hypoplasia or dysplasia, reflux nephropathy, polycystic kidney disease—Glomerular disease: Focal segmental glomerulosclerosis (FSGS).—Others: Hemolytic uremic syndrome, genetic diseases (tyrosinosis, oculocutaneous Alport syndrome), interstitial nephritis—Rare in childhood: Diabetic nephropathy and hypertension

TREATMENT
GENERAL MEASURES
• In chronic interstitial renal disease with polyuria/polydipsia, more fluid and sodium are needed to maintain euvolemia.
• In both groups, attention to potassium and phosphorus load is important.
• ACE inhibitors and angiotensin receptor blockers (ARB) are used for glomerular-based renal disease because of proteinuria but are contraindicated in possible pregnancy (birth defects) and low GFR (renal failure, hyperkalemia).
• All NSAIDS should be avoided. Levels of potential hypertensive agents (epoetin, darbepoetin) are used for anemia.
• Protein restriction, used in adult CKD to slow disease progression, cannot be used with kids as this would further hinder their growth and development.
• Nutrition is important: At least 2 g/kg/d protein stores and growth.
• Other renal diseases such as focal sclerosis maybe less amenable to therapy.

TREATMENT
First Line
• Treatment of metabolic acids with either liquid form of Bicara or the pill form of bicarbonate to normalize the CO₂. This will preserve growth as well as bone integrity.
• Treatment of phosphorus restriction, phosphorus binders such as calcium acetate or sevelamer products, and institution of vitamin D to preserve and prevent secondary hyperparathyroidism and prevent bone disease.

Second Line
• Those that were mentioned above including antihypertensive agents if indicated.
• Often ACE inhibitors and angiotensin receptor blockers (ARB) are used for glomerular-based renal disease because of proteinuria but are contraindicated in possible pregnancy (birth defects) and low GFR (renal failure, hyperkalemia).

SURGERY/OTHER PROCEDURES
In TID, patients may require cystoscopy with ablation of PUV. UPJ or UVJ obstructions may need to be corrected. Reflux may need to be corrected, if high grade and not resolving spontaneously.

ADDITIONAL TREATMENT
Radiation Therapy
• NJA.

Additional Therapies
• Diagnosis is oral or intravenous pyelogram to identify dilated renal calyces.
• Ability to retain contrast during the radiologic procedures.

Complementary & Alternative Therapies
• Nutrition: It is important to provide adequate intake of calories and protein to ensure growth.

ONGOING CARE
PROGNOSIS
• Difficult to predict early in life.
• Lack of renal growth with a creatinine greater than 1 at a year of age, associated hematuria, proteinuria, and hypertension in patients with TID portends the need for future dialysis and transplantation.

COMPLICATIONS
• Growth impairment in children is a known complication, independent of the etiology of CKD (2).
• Hypertension is also a risk factor.
• Protein restriction, used in adult CKD to slow disease progression, cannot be used with kids as this would further hinder their growth and development.

FOLLOW-UP
• Neonates and infants should be seen as frequently as they develop, in order to ensure maintenance of euvelema.
• Primary care physicians need to be instructed that patients with interstitial disease will get dehydrated more quickly than the average patient; therefore, attention to their care at the time of vomiting and diarrhea is important for these patients will become volume depleted in a hurry.

Patient Monitoring
• Glomerular based renal diseases are associated with salt and water restriction as well as blood pressure control.

Patient Resources
• American Society of Pediatric Nephrology. www.aspneph.com/patient/patient.asp
• National Kidney Disease Educational Program. www.kidney.org/patients
• NKF Care, Patient Information Center. www.kidney.org/patients

• Megacyst, Congenital
• Pediatric Urethral Valves
• Prune Belly (Eagle-Barrett or Triad) Syndrome

CODES
ICD9
• 586.39 Other congenital malformations of bladder and urethra

ICD10
• N03.9 Chronic kidney disease, unspecified
• N05.8 Other specified anomalies of bladder and urethra

CLINICAL/SURGICAL PEARLS
• Patients with interstitial disease or obstructive uropathy require IU hydration while APD prior to procedures.
• In contrast to adults, diabetes nephropathy and hypertension are rare causes of CKD in children.
• Small changes in creatinine reflect large changes in GFR for children with CKD.
• Baseline creatinine with attention to any changes after potential renal insult (CT contrast, hypervolemia/hypertension, medications, etc.) is an important measure for monitoring and prevention of progression of CKD.
CHYLOUS ASCITES
Brett S. Carver, MD

BASICS
DESCRIPTION
Chylous ascites is characterized by the accumulation of chyle in the peritoneal cavity. Results from the obstruction or injury of the thoracic duct or cisterna chyli of the lymphatic system. Lymphatic leakage from the lymph vessels draining the intestines. Characterized as a milky fluid due to the high triglyceride component. This section focuses primarily on chylous ascites associated with retroperitoneal lymph node dissection (RPLND) for testicular cancer.

EPIDEMIOLOGY
Incidence
Chylous ascites is reported to occur in ~1% of patients undergoing a primary RPLND for testicular cancer and 3% of postchemotherapy RPLNDs.

PREVALENCE
N/A

RISK FACTORS
Predisposing factors for chylous ascites associated with RPLND:
– Surgical resection of the vena cava.
– Suprahilar dissection.
– Simultaneous hepatic resection.
– In addition, patients undergoing reoperative RPLND are at an increased risk.

Genetics
N/A

PATHOPHYSIOLOGY (1)
Chylous ascites is caused by injury or obstruction of the thoracic duct or cisterna chyli. Surgical injury, ligation of the thoracic duct. Retroperitoneal tumor associated with obstruction of the thoracic duct. Leakage of fat containing lymphatic fluid into the peritoneum.

ASSOCIATED CONDITIONS
– Testicular cancer
– Peritonitis
– Fist or small-bowel obstruction
– Failure to thrive

DIAGNOSIS
HISTORY
Patients often present following RPLND with symptoms of abdominal distention and pain, decreased appetite, nausea, and vomiting. Shortness of breath may also be present associated with increased abdominal pressures. Secondary infection associated with peritonitis with symptoms of fever, chills, abdominal pain, and lethargy.

PHYSICAL EXAM
The most common finding on physical exam is distension of the abdomen with flank bulging. The abdomen is dull to percussion and may demonstrate a fluid wave upon palpation.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Serum tumor markers (AFP, HCG, LDH) should be obtained to rule out recurrence.
– Aspiration of the abdominal fluid reveals a milky white fluid, which should be sent for triglyceride testing and culture to rule out a secondary infection.
– A fluid triglyceride level >110 mg/dL is diagnostic.

Imaging
– CT scan of the abdomen and pelvis is the imaging modality of choice to evaluate for the presence of ascites and rule out retroperitoneal recurrent disease.
– Abdominal ultrasonography may be used to document ascites and guide aspiration.

Diagnostic Procedures/Surgery
Abdominal paracentesis is performed to aspirate the ascites for diagnostic testing.

Pathologic Findings
Chylous ascites is grossly defined as a milky white fluid. Lab testing will reveal elevated triglyceride content.

DIFFERENTIAL DIAGNOSIS
Chylous ascites can be caused by other conditions beyond RPLND for testicular cancer:
– Postoperative
– Abdominal aneurysm repair
– Peritoneal dialysis catheter placement
– Infectious/inflammatory
– Pancreatitis
– Retroperitoneal irradiation
– Renal disease
– Geriatric disease
– Retroperitoneal fibrosis
– Sarcoid
– TB
– Filariasis
– Mycobacterium avium-intracellulare (AIDS related)
– Neoplasm
– Lymphoma
– Kaposi sarcoma
– Other solid tumors
– Other causes
– Cirrhosis
– Carcinoid
– Nephrotic syndrome
– Trauma
– Right-sided heart failure
– Dilated cardiomyopathy
– Idiopathic
– Congenital causes (defects of lacteal formation)
CHYLOUS ASCITES

TREATMENT

GENERAL MEASURES
- All patients with abdominal distention following an RPLND should be evaluated for:
  - Ascites (nonchylous)
  - Ileus
  - Small-bowel obstruction
  - Recurrent disease in the abdomen or retroperitoneum.
- The majority of chylous effusions will heal spontaneously. Abdominal paracentesis is diagnostic and often therapeutic in relieving symptoms associated with increased abdominal pressures.

MEDICATION
First Line
- Low lipid, high medium chain triglyceride oral diet.
  - MCT oil supplement
    - 1 tablespoon (15 mL) 3–4 times/d
    - Mix with juices or otherwise incorporated into low-fat diet
  - Do not use in patients with advanced cirrhosis: Risk of narcosis and coma
- Somatostatin analogs have been demonstrated to be effective in reducing lymphorrhagia.
  - Octreotide 100 mcg administered subcutaneously 3 times per day

Second Line
- Total parental nutrition is to be utilized in patients who fail oral diet modifications.
  - Bowel rest may enhance recovery if conservative approaches are not successful

SURGERY/OTHER PROCEDURES
- Abdominal paracentesis, repeated as necessary.
- Surgical exploration with direct ligation of lymphatic vessels for persistent chylous ascites.
- Peritoneal venous shunts for refractory chylous ascites.
- Direct lymphatic vessel ligation or embolization of large leaking vessels using interventional radiologic techniques.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
Orlistat (Xenical) has been used successfully in a nontesticular cancer case of chylous ascites (3).

ONGOING CARE

PROGNOSIS
The prognosis is excellent for the vast majority of cases as most will respond to conservative management.

COMPLICATIONS
- The complications of chylous ascites related to increased abdominal pressure:
  - Renal failure
  - Venous thrombosis
  - Pulmonary embolism
  - Atelectasis
  - Pneumonia
- The gastrointestinal complications of chylous ascites include ileus and small-bowel obstruction.
  - Malnutrition and failure to thrive may also occur due to protein-losing enteropathy with chylous diarrhea (steatorrhea), malabsorption, and malnutrition

FOLLOW-UP
Patient Monitoring
- Follow-up protocols should be followed according to guidelines established by the National Comprehensive Cancer Network for testicular cancer patients.
- After initial treatment of chylous ascites, patients should be seen in follow-up to monitor for recurrent ascites.

Patient Resources
N/A

ADDITIONAL READING
- See Also (Topic, Algorithm, Media)
  - Chylous Ascites Image ID
  - Lymphatic Ascites
  - Testis Cancer, Adult General Considerations

CODES

ICD9
- 225.9 Unspecified filariasis
- 407.8 Other noninfectious disorders of lymphatic vessels

ICD10
- B74.9 Filariasis, unspecified
- I89.8 Other noninfective disorders of lymphatic vessels and nodes

CLINICAL/SURGICAL
- Chylous ascites occurs in ~1–3% of patients undergoing a RPLND.
- Risk factors include vena cava resection, suprahilar dissections, and concomitant hepatic surgery.
- Initial management includes pancrtoscopy for symptom of pain or pulmonary compromise and low lipid, high medium-chain triglyceride oral diet.

REFERENCES
CHYLURIA
Matthew A. Uhlman, MD, MBA

BASICS

DESCRIPTION
- Chyluria is the presence of chyle (a combination of lymphatic fluid and triglycerides) in urine
- Presents as milky white urine that can be constant or present primarily after meals
- Often self-limited or resolves with conservative treatment including dietary changes
- Extended chyluria can lead to malabsorption, vitamin deficiencies, and immunosuppression (due to depletion of fat soluble vitamins)[1][C]

EPIDEMIOLOGY

Incidence
- 2–10% of patients infected with filariasis can develop chyluria [2][C]
- Extremely low rates of clinically significant chyluria [1][C]
- Clinically significant in <1% of postoperative patients

Prevalence
- 120 million people suffer from filariasis worldwide, primarily in Asia, Africa, Pacific Islands, and South America [2][C]
- Chyluria is a manifestation of chronic infection, most often by Wuchereria bancrofti, Brugia malayi, or Brugia timori [2][C]
- Rare in developed countries

Nontropical chyluria
- Most often caused by trauma, renal surgery, infection, mass effect (AAA, tumor, abscess), pregnancy, or congenital abnormality [1][C]

RISK FACTORS

Parasitic chyluria
- In B. bancrofti, B. malayi, and B. timori are primary causes of filariasis. All are transmitted by mosquitoes. Less common parasitic infections have been reported to cause chyluria (Leishmania, Behcets, diphtheria, ascariasis) [1,2][C]

Nontropical chyluria
- Renal parenchymal surgery (most often radical or partial nephrectomy, RFA, or renal tumors) [1,3][C]
- Trauma
- Mass effect: Renal tumors (primary or metastatic) or lymphangiography
- Infection: TB, abscess
- Acute aneurysm
- Pregnancy
- Congenital fistula or lymphangioma

PATHOPHYSIOLOGY

Parasitic
- Adult filariae cause lymphangiitis
- Obstruction of suprarenal lymphatics (thoracic duct or upper retroperitoneal lymph drainage)
- Results in rupture of lymphatic vesicles in the thoracic duct, forming intestinal lymphatic urinary fistula
- Lymphatic HTN, with vascular incompetence:
- With obstruction between intestinal vessels and thoracic duct, the resulting cavernoous malformation opens into the urinary system, creating a fistula
- Common fistula sites are renal venous, pelvicalyceal system, urethra, and ureter
- Less commonly caused by external compression or trauma

Nontropical
- Disruption of peripelvic lymphatics during surgery allows backflow into pelvicalyceal system [1][C]
- Congenital fistulous connections between urinary tract and lymphatic system have been described, primarily in children

ASSOCIATED CONDITIONS

W. bancrofti, B. malayi, and B. timori are considered the three causative agents of lymphatic filariasis. Mosquitoes serve as vectors for all 3 nematodes [2][C]

GENERAL PREVENTION

Control of mosquito vector that transmits W. bancrofti, B. malayi, and B. timori [2][C]
- Insect repellent and mosquito nets in endemic areas
- Diethylcarbamazine (DEC) fortified salt
- Annual DEC + albendazole are used to treat asymptomatic filariasis via action on microfilariae

DIAGNOSIS

HISTORY
- Patient complaints of intermittent or continuous milky or cloudy urine
- If intermittent, most often occurs following meals
- Country of origin of patient:
- Asia, Africa, Pacific Islands, South America
- Travel to tropical regions
- History of trauma
- History of renal surgery within prior 2 yr
- History of TB exposure/infection
- Significant weight loss, anemia, lower urinary tract symptoms (frequency, urgency, dysuria), hematuria, nutritional deficiency, proteinuria, or signs of immunosuppression
- Heavy chyluria can cause distal colic or rarely, urinary retention

PHYSICAL EXAM
- Evaluation of lower limbs and genitals
- Lymphadenopathy/lymphangitis
- Male groin exam may reveal hydrocele or epididymitis
- Palpable abdominal or flank mass
- Chylous output from surgical wound or surgical drain

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis typically positive for albuminuria
- Roserandurinary triglycerides
- Fat globules in urine identified by Sudan III stain
- Peripheral blood eosinophilia, may indicate parasitic infection
- Evaluate for TB (if clinically indicated) (tuberculin test, urine stain, and culture for acid fast bacillus)
- ICT antigen card test (immunochromatographic card test, a commercial assay) is widely used in the diagnosis of W. bancrofti
- WBR rapid and panel rapid (2 commercially available assays) tests detect W. bancrofti, B. malayi, and B. timori

Imaging
- Abdominal/pelvic CT (3,4)[B]
- Include retroperitoneal mass
- Fat fluid level seen in the urinary tract
- Can demonstrate contrast communication between collecting system and perinephric collection but does not show communications between perirenal collection and lymphatics
- Lymphangiography (traditional or magnetic resonance) demonstrates abnormal lymphatics and entrance of contrast material into renal collecting system
- Angiography: Can be useful in delineating site of fistula, though not as precise as lymphangiography

Retrograde pyelography
- Rarely warranted, but may show effuse pyelographic backflow

Diagnostic Procedures/Surgery
- Blood smear: Examine for microfilaria (early stage in life cycle of nematodes) using Giemsa stain
- Cystourethroscopy: Can help localize site of milky effusion of urine. Rarely, effuse seen from bladder or posterior urethra
- Retrograde pyelography: Rarely warranted, but may show effuse pyelographic backflow
**Parasitic Chyluria**

Some fats—recommendations are often for fat-free or very low-fat diet, though this should not be observed for 90% of which are in the form of triglycerides.

**TREATMENT**

**GENERAL MEASURES**

- **Nontropical**
  - Up to 50% of cases resolve spontaneously under dietary restriction (10).  
  - Bed rest and/or use of abdominal binder to increase abdominal pressure may allow spontaneous closure.
  - Medium-chain triglyceride (MCT) diet (avoids chylomicrons through lymphatics)
  - Ureteral stent placement to reduce renal pelvis pressure

**MEDICATION**

Dietary modifications to reduce chylomicrons in diet—recommendations are often for fat-free or very low-fat diet, though this should not be observed for more than several weeks given the body’s need for some fats.

**Parasitic Chyluria**

- **DEC and albendazole, or levamisole and albendazole**
- **DEC fortified salt** can be used to treat and prevent lymphatic filariasis.

**SURGERY/OTHER PROCEDURES**

- Procedures of choice involve disconnection of renal plexus lymphatics (5,13,6)[C]
  - **Nephrolysis**: Stripping and ligation of all lymphatic vessels to the kidney and upper ureter; open and laparoscopic techniques described
  - Laparoscopic transabdominal and retroperitoneoscopic approaches described
  - Success rates 80–98%; recurrence rates 3–25%
  - Endoscopic coagulation of fistula
  - Lymphangiovenous anastomosis with ligation of renal lymphatics
  - Renal autotransplantation
  - Nephrectomy was described prior to minimally invasive techniques

**FOLLOW-UP**

**Patient Monitoring**

- Treatment failures are readily apparent as urine returns to milky color (1,13)[CA]
- Re-evaluate if chyluria recurs following treatment; consider the contralateral kidney as the source

**Patient Resources**

CIRCUMCISION, ADULT CONSIDERATIONS
Irvin H. Hirsch, MD

BASICS

DESCRIPTION
Circumcision involves the removal of the prepuce. This section addresses adult circumcision issues.

Adult circumcision is indicated for elective treatment of balanitis (glans inflammation), posthitis (prepuce inflammation), removal of preputial lesions, and at patient request for cultural and religious preference.

Emergent circumcision may be necessary for treatment of paraphimosis after failed attempt at manual reduction.

Circumcision may be necessary as part of surgical procedures requiring degloving exposure of the penis (penile fracture repair or Peyronie disease).

Circumcision is the most common operation performed worldwide.

There is some controversy concerning the need for circumcision and potential effects on sexual satisfaction. This is weighed against the potential health benefits.

EPIDEMIOLOGY
Incidence
N/A

Prevalence
Male circumcision, largely in newborns, is performed in 77% of US males and in 30% of males worldwide.

Circumcision rate in newborns has declined from 83% in the 1960s to 77% in 2010.

These incidence rates do not include out-of-hospital circumcisions.

Increasingly adult circumcision has been advocated as an important adjunct to STD and HIV prevention in developing countries (1).

RISK FACTORS
Diabetes mellitus
Genital lesions

PATHOPHYSIOLOGY

The prepuce serves as a specialized, junctional mucocutaneous tissue marking the boundary between mucosa and skin; it is similar to the eyelids, anus, and lips.

Conditions that can cause problems:
- Lack of genital hygiene
- Chronic balanoposthitis may lead to phimosis

ASSOCIATED CONDITIONS
- Diabetes mellitus
- Balanitis
- Lichen sclerosus/enthesial stricture
- Penile condylomata
- Squamous cell carcinoma
- Erectile dysfunction
- Peyronie disease

ALERT
The American Urologic Association (AUA) policy statement now considers circumcision to be of a health benefit, citing a 50-60% risk reduction in HIV transmission in some African nations.

GENERAL PREVENTION
Local hygiene measures may prevent balanitis and its sequelae.

Although male circumcision should not be substituted for other HIV risk-reduction strategies, it has been shown to reduce the risk for HIV and some STIs in heterosexual men.

Despite these data, male circumcision has not been demonstrated to reduce the risk for HIV or other STIs among men who have sex with men (MSM).

Good visualization of the glans penis is crucial in all cases of circumcision to limit complications.

DIAGNOSIS

HISTORY
- Penile pain with or without erection
- Dyspareunia
- Postcoital pain

PHYSICAL EXAM
- Inability to retract prepuce (phimosis)
- Inability to reduce prepuce (paraphimosis)
- Penile erythema or exocytosis
- Glans erythema
- Malodorous secretion (smegma)
- Associated penile lesion

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- UA
- Urine culture if indicated
- STD testing if indicated

Imaging
N/A

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Acute and chronic inflammation
- Plasma cell infiltrate (Zoon balanitis)
- Lichen sclerosus (BMD balanitis xerotica obliterans)

DIFFERENTIAL DIAGNOSIS
N/A

TREATMENT

GENERAL MEASURES
Circumcision for balanitis in adults should be performed after exhausting nonsurgical medical approaches.

MEDICATION
First Line
- Topical antibiotics
- Topical steroids
- Topical antifungals

Second Line
N/A

SURGERY/OTHER PROCEDURES

General anesthesia may be utilized.

Local anesthesia is recommended when tolerated.

Ultrasonic/bipolar cautery is injected at the level of the infrapubic bone and around the base of the penis. Avoid epinephrine.

Technique is selected based on surgeon’s preference: Sleeve technique or dorsal slit circumcision.
CIRCUMCISION, ADULT CONSIDERATIONS

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
For high risk or anticoagulated patients an isolated dorsal slit may be oversewn without circumcision.
Nonsurgical preputial compression devices are currently under investigation for HPV, HSV, and HIV risk reduction programs in developing countries (Prepex or Shang Ring). The prepuce sloughs after 7 days.

ONGOING CARE

PROGNOSIS
Patient satisfaction is high

COMPICATIONS (2)
- The majority of complications relating to circumcision are minor and should be easily treated
- While very infrequent, challenging complications requiring complex reconstructive surgery and should be referred to a center specializing in these reconstructions.
  - Early
    - Hematoma and bleeding
    - Infection
    - Urethral stricture due to tight bandaging
    - Glans necrosis
    - Removal of inadequate or excessive skin
    - Partial penile amputation
  - Late
    - Urethral injury/urethrocutaneous fistula
    - Neural stress
    - Hyperesthesia or hypoesthesia of penis
    - Penile scarring and deformity
    - Skin bridges between the glans and penile shaft
    - Concealed/buried penis
    - Inclusion cysts
    - Erectile dysfunction

FOLLOW-UP

Patient Monitoring
- Routine postoperative care.
- Follow for alterations in penile sensation and erectile function.

Patient Resources
www.aafp.org/afp/1999/0315/p1514.html

CLINICAL/SURGICAL PEARLS
- These measures reduce risk of neural injury: minimize use of electrocautery and limit excision superficial to Buck fascia
- Ablate hemostasis of tunica albuginea
CIRCUMCISION, PEDIATRIC CONSIDERATIONS

Mary Ellen T. Dolat, MD
Harry P. Koo, MD, FAAP, FACS

DESCRIPTION

Circumcision: are the surgical removal of the foreskin (prepuce) from the penis.

- One of the oldest surgical procedures
- One of the most commonly performed surgical procedures in practice today.
- There is some controversy concerning the need for circumcision and potential effects on sexual dissatisfaction in adulthood. This is weighed against the potential health benefits.

EPIDEMIOLOGY

- Few data are available to help estimate accurately the number of newborns circumcised worldwide.
- Countries of origin, ethnicity, religious affiliation, and birth in a rural vs. an urban hospital clearly influence a child’s likelihood of being circumcised.
- In addition, lack of (or the type of) health insurance may influence a child’s likelihood of being circumcised.
- Most common reasons reported by US parents for choosing circumcision:
  - Health/medical benefits including hygiene (40–60%),
  - Social concerns (23–37%),
  - Religious requirements (11–19%)

Incidence

- Circumcision rate in newborns has declined from 83% in the 1960s to 77% in 2010.
- These incidence rates do not include out-of-hospital circumcisions.
- 79% of men surveyed reported being circumcised prior to sexual activity.

Prevalence

- Most neonates have a physiologic phimosis or balanitis.
- A small percentage (5–10%) of newborns are at risk for infection.
- The penis should be carefully examined before the infant is circumcised.

Risk Factors

- Urinary tract infection
  - An increased risk for UTI in uncircumcised males younger than 1 yr: risk being greatest toward the 1st 6 mo.
  - Given that the risk of UTI in infant males is ~1%, the number needed to circumcise to prevent UTI is ~100.
  - The benefits of male circumcision are, therefore, likely to be greater in boys at higher risk for UTI, such as infants with underlying anatomical defects:
    - Need for future circumcision
    - Future medical complications for boys (and men) who are uncircumcised as newborns: balanitis, severe phimosis, and paraphimosis.
    - For parents, there exists a ~2–5% risk that their sons will need a circumcision for a medical indication if they choose not to circumcise their sons as newborns (2)

PATHOPHYSIOLOGY

- The foreskin serves as a specialized, junctional mucocutaneous tissue marking the boundary between mucosa and skin. It is similar to the eyelids, anus, and lips.
- Most neonates have a physiologic phimosis, affecting most newborns until about 1 month of age.
- During childhood, the growth of the prepuce body, accumulation of epithelial cells, and intermittent penile erections eventually separate the prepuce from the glans, permitting retraction.
- During the first 6 mo of life, there are more uropathogenic organisms around the urethral meatus of an uncircumcised male infant than around those of circumcised male infants; this colonization decreases in both groups after the first 6 mo (3).
- Boys with vesicoureteral reflux who are uncircumcised have a higher risk of UTI.

ASSOCIATED CONDITIONS

- Phimosis
- Paraphimosis

GENERAL PREVENTION

- Gentle periodic retraction during the newborn period will help prevent phimosis for the inability to retract foreskin later in life.

DIAGNOSIS

- History
  - Prior history of phimosis or balanitis
  - Prior history of meatalitis
  - Report of “ballooning” of the distal foreskin during voiding
  - Prior history of circumcision
    - Incomplete removal of foreskin
    - Congenital phimosis
  - Some parents report “infected whitish pus,” which in most instances is due to normal secretion of smegma

PHYSICAL EXAM

- In newborns, perform a complete male genital exam in a baby with nonpalpable testes may be due to congenital adrenal hyperplasia
- Look for penile developmental variations that may be a contraindication of a newborn circumcision (see “Diagnosis”)
- Same instance with newborns with incomplete foreskin development (ie, does not have natural phimosis), may still be amenable to a newborn clamp circumcision

DIAGNOSTIC TESTS & INTERPRETATION

- Lab: Not necessary unless there is suspicion for intersex anomaly
- Imaging: Not necessary unless there is suspicion for intersex anomaly
- Diagnostic Procedures/Surgery: Not necessary unless there is suspicion for intersex anomaly

PATHOLOGIC FINDINGS

- Risk

DIFFERENTIAL DIAGNOSIS

- The foreskin should be carefully examined before the procedure to identify the following conditions that may preclude a circumcision:
  - HYPOSPADIA
  - EPISPADIAS
  - HYPOSPADIAS
  - CHordee
  - Microphallus
  - Foreskin that obstructs voiding

- Recommend obtaining a pediatric urology consultation to determine whether the baby would be a candidate for newborn circumcision

TREATMENT

- Remove the foreskin
- Circumcision: 2 ways of preventing penile cancer:
  - Western nations: “Routine” newborn circumcision (not recommended)
  - Scandinavian countries (low prevalence of circumcision) and in Israel (high prevalence of circumcision) and in Scandinavian countries (low prevalence of circumcision).
  - Recommend obtaining a pediatric urology consultation to determine whether the baby would be a candidate for newborn circumcision

ALERT

- In cases of Disorders of Sexual Development (DSD) with sex assignment concerns or significant anomaly such as hypospadias the infant should not undergo newborn circumcision.

GENERAL MEASURES

- The AAP states that the health benefits of newborn male circumcision outweigh the risks but the scientific evidence is not strong enough for the AAP to recommend routine circumcision of all newborns. The AAP advises parents to learn the facts about circumcision and weigh the risks and benefits.

- Most routine circumcision is performed between 2 and 10 days of life.
### Ongoing Care

**Prognosis**

Some groups believe that circumcision may reduce or increase the possibility of the risk of the penis, potentially impacting sexual pleasure later in life. The data are conflicting and mostly these subjective findings are not conclusive.

**Complications**

- **Large US hospital-based studies estimate the risk of a significant acute circumcision complication to be between 0.19–0.22%**.
- **From newborn circumcisions using clamp techniques**:
  - **Gomo clamp**: Mainly related to technical factors
  - **Insufficient or inadequate skin removal requiring additional revision procedure**: Since the metal bell completely covers the glans, glans injury is extremely rare
  - **Plastibell**: Insufficient or inadequate skin removal requiring additional revision procedure
  - **Incomplete circumcision**: Retained Plastibell ring
  - **Mogen clamp**: Potential for injury to glans, including partial amputation
  - **Immediate complications**: Significant bleeding (0.08–0.18%)
  - **Postcircumcision bleeding may be the 1st manifestation on an underlying bleeding disorder**
  - **Significant infection (0.36%)**: Significant penile injury (0.04%)
  - **Late complications**: Phimosis (acquired)
  - **Adhesions**: Skin bridges
  - **Excess skin**: Insufficient penile skin
  - **Peri-urethral infection**: Peri-urethral infection
  - **Peri-urethral inflammation**: Peri-urethral inflammation
  - **Hymenostomy fistula**: Peri-urethral fistula

**Follow-up**

- **Patient Monitoring**: A small amount of petroleum jelly may help with discomfort due to diaper friction the 1st few days postop.
- **Bandaging** is optional after the 1st 1–2 days.
- **Diapering** usually takes place within 10 days.
- **Clean site with warm water and avoid baby diaper wipes**.

**Patient Resources**

American Academy of Pediatrics, Patient Education ONLINE. www.patiented.aap.org

### Codes

- **ICD9**: Z41.2 Encounter for routine and ritual male circumcision
- **ICD10**: Z90.872 Male genital surgical procedures; not elsewhere classified

### Additional Reading

### Additional Pearls

- Make sure to carefully inspect the penis for any congenital defects such as hypospadias or chordee before proceeding with neonatal circumcision. It is best to delay circumcision until the primary defect can be repaired as the foreskin may be used in reconstructive procedures.
- The choice of neonatal circumcision is a matter of the physician’s personal preference. For circumcisions using a Gomo clamp, or Plastibell, select the correct size of the bell; this would ensure adequate foreskin removal.
- Always consider the cultural and religious beliefs of the family when counseling about newborn circumcision.

### Additional Treatment

- **Radiation Therapy**: Not recommended
- **Additional Therapies**: Not recommended
- **Complementary & Alternative Therapies**: Traditional religious providers perform the procedures in community settings.
CONDYLOMA ACUMINATA (VENERAL WARTS)
Neal Patel, MD
Allen D. Seftel, MD

**DESCRIPTION**
- Anogenital epidermal lesions caused by the transmission of human papilloma virus (HPV).
- The most common viral sexually transmitted infection in the US, they are also called genital warts, or venereal warts.
- Most common sites: Penis, vulva, vagina, cervix, perineum, and perianal area.
- Less commonly, urethra, bladder, oropharynx, larynx, and trachea.

**Epidemiology**
- **Incidence:**
  - Most common STD
  - ~ 1% of sexually active adults in the US
- **Prevalence:**
  - Highest prevalence: 18–28 yr olds and exceeds 50% of the US population
  - HPV 6 and 11 account >90% of visible genital warts.

**Risk Factors**
- Increased risk with number of sex partners, frequency of sexual activity, early coitus, and presence of condylomata on partners.
- Age <25
- Immunocompromised status
- Cigarette smoking and oral contraceptives may be associated with an increased risk.
- Onset of sexual activity at an early age

**Pathophysiology**
- HPV is a double-stranded, circular DNA genome consisting of ~8,000 base pairs. Subtypes 6 and 11 are associated with the majority of genital warts.
- Types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, and 80 different subtypes can potentially associate with condylomata.
- Basal layer of epidermis is invaded by the virus.
- Transmission is by direct sexual contact.
- Less common route is autoinoculation from nongenital lesions.
- Vascular layer of epithelium is invaded by the virus.

**Associated Conditions**
- Perineal cancer
- Anogenital lesions
- Buschke-Löwenstein tumor
- Male: Examine penis, meatus, scrotum, perineum, and suprapubic, and perianal region.

**Diagnosis**
- **History:**
  - Age and sex of patient
  - History of recent sexual exposure
  - Number of partners and frequency of sexual intercourse
  - Visible warts usually seen within 2–3 mo after exposure
  - Practice of anal intercourse
  - Immunocompromised state

**Physical Exam**
- Lesions are pinkish to red-grayish white, papillary lesions found on moist surfaces, often coalescing.
- Lesions appear pearly-white and granular.
- Larger lesions may be verrucous or flat in configuration.
- With magnification, a central vascular can be seen within each projection.
- Male: Examine penis, meatus, scrotum, perineum, suprapubic, and perianal region.
- Female: Labia, introitus, perineum, cervix, and perianal region.
- Examine for evidence of coexisting STD (ulcers, discharge, adenopathy).

**Diagnostic Tests & Interpretation**
- The most common viral sexually transmitted disease in the US, they are also called genital warts.
- **Onset of sexual activity at an early age**

**Pathologic Findings**
- Branching, villous, papillary connective tissue stroma covered by epithelium.
- Superficial hyperkeratosis and thickening of the epidermis (acanthosis).
- Clear vacuolization of the prickle cells (koilocytosis), characteristic of HPV infection, is seen.
- There is no evidence of invasion of the underlying stroma.

**Differential Diagnosis**
- Bowen disease and erythroplasia of Queyrat
- Bowenoid papulosis
- Basal cell carcinoma
- Condyloma latum (syphilis)
- Extramammary Paget disease
- Fibroepitheliomas
- Herpes simplex virus
- Malignant melanoma
- Mild mucocutaneous candidiasis
- Nevi
- Pearly penile papules
- Seborrheic keratosis
- Squamous cell carcinomabasaloid cell carcinoma

**Treatment**
- **First Line**
  - Podophyll (Podophyllin 25%, Podcon, Podofilin): Applied to lesion (concentration 10–25%) by hand physician
  - Podophyll (Cordyline): Self-application of 0.5% solution to warts twice daily for 3 days, followed by 4 days without treatment; can be repeated 4–6 times.
- **Second Line**
  - 5-FU (Efudex, Fluoroplex): Topical therapy may take up to 3 mo to observe a response.
  - 5-FU (Cordyline): Self-application of 0.5% cream 1–3 times per day for several weeks, as needed. Maybe also used as an intralesional instillation but not without intensive complications.
CONDYLOMA ACUMINATA (VENERAL WARTS)

- **Therapeutic agents (Immunotherapy):**
  - An 80–90% virological cure of therapeutic agents; apply directly to lesions; repeat weekly
  - Ipratrophine (4mg)
    - Agents of interferon-α, which enhances cell-mediated cytolytic activity. Available as a 5% cream applied to external lesions 3 times per week up to a maximum of 16 wk

**Second Line Procedures**

- **Electrocoagulation/Laser: Application of liquid nitrogen on skin lesions**; local anesthesia is usually sufficient
- **Holmium laser can be used to remove intraurethral warts**; magnification necessary to maximize efficacy; may produce less scarring
- **Cryotherapy: Application of liquid nitrogen on patients without extensive disease**; this procedure can be repeated at 1- or 2-wk intervals.
- **Interferon-α– Potent inducer of interferon cell-mediated cytolytic activity. Available as a 5% cream applied to external lesions 3 times per week up to a maximum of 16 wk**

**ONGOING CARE**

**PROGNOSIS**

- Subclinical infections are probably not curative.
- Women should still undergo routine Pap smears.
- Malignant transformation of genital cells, but it may be a cofactor in development of malignancy. HPV 6 and 11 are considered low-risk subtypes, and are seldom associated with malignancy.
- Nonsmokers are at 25–50 times greater risk for malignancy

**COMPLICATIONS**

- Malignant transformation: Perineal carcinoma, cervical carcinoma, anal carcinoma, and Buschke-Löwenstein tumor

**FOLLOW-UP**

**Patient Monitoring**

- Educate the patient about self-exam.
- Patients should be examined shortly after therapy, to evaluate initial response rates.
- Encourage use of condoms if sexually active.
- Surveillance urothroscopy is recommended 3–6 mo after treatment of intrarectal lesions.

CONTRAST ALLERGY AND REACTIONS

Edouard J. Trabulsi, MD, FACS
Leonard G. Gomella, MD, FACS

DESCRIPTION

Allergy reactions to IV contrast used for radiologic imaging are common, can range from mild to moderate, and occasionally life threatening.

Often an immune system-based response to IV administration of contrast used for common urologic studies such as excretory urography and CT.

Contrast allergy and reactions can be divided into 3 groups:

- Idiosyncratic anaphylactoid reactions
- Nonidiosyncratic reactions
- Delayed reactions

Reactions to MRI contrast media are discussed in Section II "Nephrogenic Systemic Fibrosis/Fibrosing Dermatopathy (NSF/NFD)."

"Contrast Induced Nephropathy" is discussed in Section II.

RISK FACTORS

History of allergy or atopy

Previous ADR

Dehydration

Cardiac disease

Asthma

Renal disease

Sickle cell disease

Renal insufficiency

Previous reaction (5 times), allergy or atopy

Dehydration

Cardiac disease

Asthma

Renal disease

Sickle cell disease

Renal insufficiency

GENERAL PREVENTION

Use of alternative imaging in patients with history of previous ADR

Preprocedure hydration

Patients with normal renal function on dialysis

Patients with pre-existing renal impairment should stop metformin before the procedure and be well hydrated to avoid RCM-related biguanide lactic acidosis and contrast-induced nephropathy.

In patients with normal renal function on metformin the following comorbidities should prompt discontinuation of metformin before the contrast:

- Liver dysfunction, alcohol abuse, cardiac failure, myoccardial or peripheral muscle ischemia, orpsis

- Limit risk for contrast-induced nephropathy, special arrangements should be made with the radiology department for any patient with a GFR <60 mL/min/1.73 m².

- Prevention in patient with known allergy:
  - Review radiology department procedures at site where testing scheduled.
  - Give methylprednisolone (Medrol) 32 mg PO 12 and 2 hr prior to scheduled test and 50 mg diphenhydramine

- Patients with allergies to other substances (food, medicines), with history of asthma, who are allergic to iodinated contrast, who are undergoing guthabism (or those with allergy to guthabism who we to receive IV contrast) DO NOT need steroid preop.

DIAGNOSIS

HISTORY (4)

- Previous ADR
- Cardiac or renal disease
- Metformin with chronic renal disease
- Allergies

PHYSICAL EXAM

- Monitor vital signs (BP, heart rate, respiratory)

- Hypotension and rare shock

- Observe for:
  - Urticaria, bronchospasm, wheezing, stridor
  - Shorness of breath, flushing, pruritus, angioedema

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- In acute setting, no labs are usually needed

- Blood gas may be useful

- Blood gas may be useful

- In patients with normal renal function on metformin the following comorbidities should prompt discontinuation of metformin before the contrast:

- Liver dysfunction, alcohol abuse, cardiac failure, myoccardial or peripheral muscle ischemia, orpsis

- Limit risk for contrast-induced nephropathy, special arrangements should be made with the radiology department for any patient with a GFR <60 mL/min/1.73 m².

- Prevention in patient with known allergy:
  - Review radiology department procedures at site where testing scheduled.
  - Give methylprednisolone (Medrol) 32 mg PO 12 and 2 hr prior to scheduled test and 50 mg diphenhydramine

- Patients with allergies to other substances (food, medicines), with history of asthma, who are allergic to iodinated contrast, who are undergoing guthabism (or those with allergy to guthabism who we to receive IV contrast) DO NOT need steroid preop.

- Review radiology department procedures at site where testing scheduled.

- Give methylprednisolone (Medrol) 32 mg PO 12 and 2 hr prior to scheduled test and 50 mg diphenhydramine

- Patients with allergies to other substances (food, medicines), with history of asthma, who are allergic to iodinated contrast, who are undergoing guthabism (or those with allergy to guthabism who we to receive IV contrast) DO NOT need steroid preop.

- Review radiology department procedures at site where testing scheduled.

- Give methylprednisolone (Medrol) 32 mg PO 12 and 2 hr prior to scheduled test and 50 mg diphenhydramine

- Patients with allergies to other substances (food, medicines), with history of asthma, who are allergic to iodinated contrast, who are undergoing guthabism (or those with allergy to guthabism who we to receive IV contrast) DO NOT need steroid preop.
First Line

Based on guidelines noted above (5):

- If hypotension MS or LR IV bolus 1 L
  with fluid response considered manifest by HR improvements
  with volume administration.
  - Hypertensive crisis (DBP > 90 mm Hg)
  - Benadryl
  - Albuterol: 2 puffs (90 mcg/puff)
  - Diffuse erythema: IV access, monitor vitals, pulse oximeter
  - Reaction rebound prevention: IV steroids help
  - Anxiety/panic attack: Diagnosis of exclusion; lorazepam 2–4 mg PO slow push; 4 mg max
  - Hypoglycemia: IV access, O2 mask; oral 2 sugar tablets
  - Pulmonary edema: IV access, monitor vitals, pulse oximeter
  - Bronchospasm: IV access, monitor vitals, pulse oximeter
  - Seizures: Protect patient; turn on side to avoid aspiration
  - With tachycardia (pulse > 100 BPM)
  - With bradycardia (pulse < 60 BPM [vasovagal])
  - Furosemide 20–40 mg PO
  - Neofundic: 180 mg PO
  - Glucagon: 1 mg IM
  - Hydrocortisone 200 mg IV over 2 min
  - Labetalol: 20 mg IV over 2 min; double dose every 10 min PRN
  - Epinephrine: 0.4 mg IV or SQ push every 5–10 min PRN
  - Nitroglycerin: 0.4 mg tablet SQ repeat every
  - Oximeter, O2 mask; consider rapid response team/911

Second Line

N/A

SURGERY/OTHER PROCEDURES

N/A

ADDITIONAL TREATMENT

Radiation Therapy

N/A

ADDITIONAL THERAPIES

For life-threatening reactions: ABCs of resuscitation, IV fluids, vasopressors for BP support if IV fluids not effective

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Depends on severity of the anaphylactic reaction and the severity of the underlying condition
- Mortality risk in severe cases: 1 in 170,000

COMPLICATIONS

- Risk of death of 1 in 170,000 for both ionic HOCM and nonionic LOCM

FOLLOW-UP

- Appropriate supportive measures until recovery
- Appropriate follow-up recommendations

PATIENT MONITORING

- Appropriate supportive measures until recovery

PATIENT RESOURCES

CLINICAL/SURGICAL PEARLS

A shellfish or iodine allergy does not correlate with contrast media allergy.
CUSHING DISEASE AND SYNDROME

John B. Eifler, MD
Michael S. Cookson, MD

BASICS

DESCRIPTION
Cushing disease is hypercortisolism due to an ACTH-secreting pituitary adenoma.
Cushing syndrome is the cluster of symptoms attributable to hypercortisolism.

GENERAL PREVENTION
Diligent management of glucocorticoid administration.

EPIDEMIOLOGY
Incidence
N/A

RISK FACTORS
Intragastric exposure to glucocorticoids
− Includes steroid creams or nasal sprays.

GENETICS
− Associated with MEN-1, Carney complex.
− GNAS1 gene mutation (McCune-Albright syndrome).

PATHOPHYSIOLOGY
− Elevated serum levels of cortisol, either from endogenous or exogenous sources.
− Hypothalamus-pituitary-adrenal (HPA) axis dysregulation.

HISTORY
− Progressive weight gain
− Fatigue
− Proximal myopathy
− Skin abnormalities: Easy bruisability, striae, and thinning of skin.

LAB
− CBC, serum electrolytes, glucose, lipids
− Elevated late-night salivary cortisol: In Cushing hypercortisolemia, not etiology
− Hyperglycemia, hypokalemia, neutrophilia, lymphopenia, hyperlipidemia consistent with Cushing syndrome.

DIAGNOSTIC TESTS & INTERPRETATION
− Plasma ACTH concentration
− Elevated late-night salivary cortisol: In Cushing syndrome, diurnal variation of cortisol levels is lost.
− ACTH-secreting tumor (failure to suppress cortisol by DST)
− ACTH-independent hypercortisolism to evaluate for adrenal adenoma/carcinoma.

IMAGING
− Brain MRI if pituitary lesion suspected.
− CT abdomen/pelvis adrenal protocol for ACTH-independent hypercortisolism to evaluate for adrenal adenoma/carcinoma.

DIFFERENTIAL DIAGNOSIS
− Alcoholism (pseudo-Cushing).
− Adrenal adenoma.
− Adrenal adenocarcinoma.
− Micronodular/macro-nodular adrenal hyperplasia.

TREATMENT
GENERIC MEASURES
− Multidisciplinary approach: Endocrinologist, neurosurgeon, adrenal surgeon.
− Surgical therapy is the mainstay of treatment.

MEDICATION
− Ketoconazole: Considered medical treatment of choice; not FDA approved for this indication.
− Mitotane: 500–750 mg 3 or 4 times a day.
− Primarily used for adrenocortical carcinoma.
− Inhibits 11β-hydroxylase.
− Side effects: Reversible hepatotoxicity, headaches, sedation, nausea, and vomiting.

REFERENCES
− Ectopic ACTH production may lead to metastases.
− Rimostil: Suppresses cortisol production by inhibiting 11β-hydroxylase.
− Primarily used for adenocortical carcinoma.

SIDE EFFECTS
− Mitotane: Supresses cortisol production by inhibiting 11β-hydroxylase.
− Metopirone: Inhibit 11β-hydroxylase.
− Gynecomastia, decreased libido, and impotence in males.
− Reduced androgen production may lead to decreased libido, decreased muscle mass.
CUSHING DISEASE AND SYNDROME

Second Line

SURGERY/OTHER PROCEDURES

- Cushing disease:
  - Trans-sphenoidal resection of pituitary adenoma: Gold standard
    - Cure in 60–80% of patients
  - Bilateral adrenalectomy if disease refractory to pituitary surgery or if life-threatening hypercortisolism
  - Ectopic ACTH-secreting tumor: Surgical resection

- Ectopic ACTH-secreting tumor: Surgical resection

- Bilateral adrenalectomy reserved for unresectable disease

- Ipsilateral adrenalectomy for primary cortisol-secreting adrenal masses

ADDITIONAL TREATMENT

Radiation Therapy

Pituitary irradiation effective in 15% of refractory cases—not considered primary therapy

ADDITIONAL THERAPIES

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prognosis good for adrenal adenoma or Cushing disease, worse for adrenocortical carcinoma

- Prognosis for ectopic ACTH-producing tumors typically poor

COMPLICATIONS

- Bilateral adrenalectomy
  - Adrenal insufficiency
  - Osteoporosis
  - Increased infection risk
  - Nelson syndrome (pituitary adenoma)

FOLLOW-UP

- Patient Monitoring
  - Postoperative monitoring for adrenal insufficiency
  - Pre- and postoperative management is complex and should be coordinated by endocrinologists
  - Post operative hydrocortisone replacement with prolonged wean to allow pituitary adrenal axis to recalibrate
  - After primary treatment (pituitary surgery), any new-onset symptoms → reevaluation

CODES

ICD9

255.0 Cushing’s syndrome

ICD10

- E24.0 Pituitary-dependent Cushing’s disease
- E24.8 Other Cushing’s syndrome
- E24.9 Cushing’s syndrome, unspecified

CLINICAL/SURGICAL PEARLS

- Initial diagnostic studies for suspected Cushing syndrome include late-night salivary cortisol and 24-h urinary free cortisol.
- Most common cause of endogenous Cushing syndrome is a pituitary adenoma.
- Muscle weakness +/− skin hyperpigmentation after bilateral adrenalectomy may be due to pituitary adenoma (Nelson syndrome).

101
CYSTITIS, GENERAL CONSIDERATIONS
Kelly A. Healy, MD
Demetrios H. Bagley, MD, FACS

DESCRIPTION

Bacterial cystitis:
- Occurs more frequently in women.
- In men, isolated cystitis is rare and often associated with prostatitis that results in secondary bacterial infection of the bladder.
- Clinical syndrome of dysuria, frequency, urgency, and suprapubic pain.
- Can be caused by infection (bacterial, viral, fungal), less commonly parasitic, radiation, interstitial cystitis (IC) or due to other irritants (drugs), or a complication of another illness.

Incidence
- Young women: Sexual activity, use of spermicidal agents.
- Adenovirus in the urine preceding transplantation.
- Postmenopausal alterations in the perineal skin and mucosa as blood type or maternal history of recurrent cystitis.
- Postmenopausal changes in the perineal skin and mucosa.
- Bacterial cystitis in females is usually an ascending infection.
- Obstetric endarteritis causing ischemia.
- Common cause of hemorrhagic cystitis thought to be due to acrolein metabolite dwelling in bladder.

Risk Factors
- Bacterial cystitis:
  - Young women: Sexual activity, use of spermicidal condoms or diaphragm, and genetic factors such as blood type or maternal history of recurrent cystitis.
  - Healthy, noninstitutionalized older women: Postmenopausal changes in the perineal epithelium and vaginal microflora, incontinence, diabetes, and history of cystitis.

Genetics
- N/A

PATHOPHYSIOLOGY

Bacterial cystitis in females is usually an ascending infection.
- In males, it occurs in association with urethral or prostatic obstruction, prostatitis, foreign bodies, or tumors.
- Increased in tumor necrosis factor in bladder mucosa.
- Increased mast cell degranulation and histamine release.
- Changes in purinergic signaling

ASSOCIATED CONDITIONS

See “Differential Diagnosis.”

GENERAL PREVENTION

- Infectious: Minimize bacterial exposure, avoid indwelling Foley catheter if possible, intermittent catheterization if prolonged catheter needed.
- Hemorrhagic: Avoid radiation or cyclophosphamide/iphosphamide exposure.

PHYSICAL EXAM

- Characterization of symptoms: Frequency, urgency, dysuria, suprapubic pain, perineal or scrotal pain, dyspareunia.
- Exposure to radiation:
  - Obliterative endarteritis causing ischemia.
  - Common cause of hemorrhagic cystitis thought to be due to acrolein metabolite dwelling in bladder.
- History of UTI; previous treatments.
- Exposure to radiation:
  - Suspect viral or fungal infection.
  - Use of personal hygiene products that can cause local irritation (douches, vaginal preparations).
- Mucosal damage:
  - Escherichia coli
  - Cystitis cystica, cystitis glandularis
  - Chronic pelvic pain syndromes
  - Interstitial cystitis
  - Dyspareunia
  - Bacterial vaginosis, lichen sclerosus
  - Gynecologic pain
  - Urethritis
  - Urethral syndrome

DIAGNOSIS

- Characterization of symptoms: Frequency, urgency, dysuria, suprapubic pain, perineal or scrotal pain, dyspareunia.
- Exposure to radiation:
  - Obliterative endarteritis causing ischemia.
  - Common cause of hemorrhagic cystitis thought to be due to acrolein metabolite dwelling in bladder.
- History of UTI; previous treatments.
- Exposure to radiation:
  - Suspect viral or fungal infection.
  - Use of personal hygiene products that can cause local irritation (douches, vaginal preparations).
- Mucosal damage:
  - Escherichia coli
  - Cystitis cystica, cystitis glandularis
  - Chronic pelvic pain syndromes
  - Interstitial cystitis
  - Dyspareunia
  - Bacterial vaginosis, lichen sclerosus
  - Gynecologic pain
  - Urethritis
  - Urethral syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- Urine culture:
  - Ananemic, sterile
  - Midstream standard
  - Catheter sample if concerns about contamination.
- Fungal and viral cultures only if high suspicion.
- CT urogram or US:
  - To rule out vesicoureteral reflux if considering intravesical formalin treatment for hemorrhagic cystitis.

DIAGNOSTIC PROCEDURES/SURGERY

- Cystoscopy for hematuria workup or if the diagnosis is not apparent.
- Cystoscopy with hydrodistention for the diagnosis of IC.
- Cystoscopy for hemorrhagic cystitis due to acrolein metabolite dwelling in bladder.
- Cystoscopy for urothelial carcinoma in situ for tissue culture.

Pathologic Findings

- Evidence of acute or chronic inflammation.
- Michaelis-Gutierrez bodies in necrotic epidermis.

DIFFERENTIAL DIAGNOSIS

- Anxiety
- Diabetes mellitus
- Bladder cancer or other malignancy
- Chronic pelvic pain syndromes
- Interstitial cystitis
- Diabetes insipidus
- Excess fluid intake
- Bladder biopsy
- Yeasts
- Candidiasis
- Eosinophilic cystitis
- Bacterial cystitis
- Yeasts
- Endometriosis
- Urethral syndrome
Based on culture if initial antibiotic not successful in Second Line

**TREATMENT**

**GENERAL MEASURES**
- Encourage adequate hydration.
- Cystoscopy with clot evacuation and electro or laser fulguration.
- Cystoscopy with hydrodistention to diagnose IC; look for characteristic glomerulations.
- Encourage voiding immediately before and after exposure to pathogens
- Encourage adequate hydration.

**COMPlications**
- Hemorrhagic cystitis may recur and/or be refractory requiring cystoscopy and fulguration.
- Simple bacterial cystitis prognosis is excellent.

**PROGNOSIS**
- Depends on etiology of cystitis
- Prostatitis
- Neurogenic bladder, chronic urinary retention
- IC (painful bladder syndrome)
- Infectious cystitis: Bacterial, viral, parasitic, fungal
- Hemorrhagic cystitis
- Extrinsic bladder compression (eg, pelvic tumor, radiation-induced fibrosis)
- EPIdymitis
- Cystitis, Radiation
- Cystitis, Hemorrhagic (Infectious, Noninfectious, Radiation)
- Cystitis, Radiation
- Acute cystitis in females is most commonly bacterial and typically responds to a short course of antibiotic.

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- May induce radiation cystitis

**Additional Therapies**
- Hyperbaric oxygen for hemorrhagic cystitis.
- Complementary & Alternative Therapies
- Cranberry tablets for prevention of recurrent bacterial cystitis; evidence that the benefit for preventing UTI is small, cranberry juice cannot currently be recommended for the prevention of UTIs.

**ONGOING CARE**

**PROGNOSIS**
- Simple bacterial cystitis prognosis is excellent.
- Depends on etiology of cystitis
- Prostatitis
- Neurogenic bladder, chronic urinary retention

CYSTITIS, HEMORRHAGIC (INFECTIOUS, NONINFECTIOUS, RADIATION)
Ahmad Shabsigh, MD, FACS

BASICS
DESCRIPTION
- Inflammation leading to damage of the bladder’s urothelium and blood vessels, causing hematuria and irritative voiding symptoms.
- Hemorrhagic cystitis (HC) is commonly caused by severe infection, cyclophosphamide, and radiation therapy induced.

EPIDEMIOLOGY
Incidence
- Cyclophosphamide-induced HC: 5–7%
- 7–70% of hematopoietic stem cell transplants.

ASSOCIATED CONDITIONS
RISK FACTORS
- No. epip, iv, or oral premedication.
- Infections.
- Exposure to certain industrial chemicals, such as aniline or toluidine derivatives.
- Previous treatment with oxazaphosphorine agents (e.g., cyclophosphamide, isophosphamide).
- History of prior pelvic radiation (prostate and cervical cancers).
- Resection of BK virus (BKV) infection in bone marrow transplant patients.

GENETICS
N/A

PATHOPHYSIOLOGY
- Cyclophosphamide: Acrolein enters the urethelium. Activates platelet-activating factor, nitric oxide, tumor necrosis factor-α, and IL-1, eventually forming peroxynitrite that causes damage.
- Radiation-induced cystitis results from a progressive osmotic abnormality leading to mucosal ischemia, ulceration, and necrosis.
- Peroxynitrite toxicity is immune-mediated, whereas danazol toxicity is likely from damaging vascular changes.

ASSOCIATED CONDITIONS
See “Differential Diagnosis.”

GENERAL PREVENTION
- Patients treated with cyclophosphamide once had a high incidence of HC (~70%), with high mortality rates (as high as 75%) if became severe.
- IV hydration, frequent bladder emptying, and sometimes indwelling catheters with bladder irrigations are used to reduce the time toxins are in contact with the bladder wall.
- Mepacrine phosphate (nocarboxylic) binds to acrolein, creating nontoxic compounds.
- WF-10 (2-A), sodium pentosan polysulfate (Epilone), and amifostine (Ethyol) have been creating nontoxic compounds.
- N-acetylcysteine (Mucomyst) binds to acrolein, forming peroxynitrite that causes damage.

TREATMENT
GENERAL MEASURES
- Catheterization/bladder irrigation with normal saline to clear bleeding and evacuate clots.
- Remove the offending train.
- Treat the infectious agent.
- Hydration and diuresis.
- Blood products transfusion, when necessary.

DIAGNOSIS

HISTORY
- Gross hematuria (with or without pain).
- Frequency, urgency, dysuria.
- Urinary retention from clots.
- Oliguria/microscopical hematuria.
- Suprapubic pain.
- Revers with drills.
- Occasional mucosal sloughing.
- Large hypertrophied tongue: Amyloidosis.

DIAGNOSTIC TESTS & INTERPRETATION
- Urine for analysis, cytology, and cultures (including fungal and viral cultures, if indicated).
- Coagulation factors (especially platelets), which can be depleted.
- Serial hematocrits.
- Blood tests for collagen disease markers, if indicated.

IMAGING
- CT-urogram: – Often done as part of hematuria workup. – Rules out other urologic abnormalities. – Usually not able to diagnose HC, but may show clots in the lumen, a widened irregular bladder wall, and/or small capacity.
- Radiopaque studies: – Penicillin, piperacillin, methicillin, carbenicillin, nonoxynol-9 contraceptive.
- Catheterization/bladder irrigation with normal saline to clear bleeding and evacuate clots.

DIFFERENTIAL DIAGNOSIS
- Acute UTIs.
- Carcinomas of the urinary tract.
- Other infections rarely cause severe HC.

Pathologic Findings
- Usually initiated by bladder distension, minor trauma, infection, instrumentation.
- Acute episodes wane within 12–18 mo.
- Can recur as late as 15–20 yr after exposure.

Acute episodes wane within 12–18 mo.
- Can recur as late as 15–20 yr after exposure.

Relief: – Usually induced by bladder distension, minor trauma, infection, instrumentation.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.
- – Usually initiated by bladder distension, minor trauma, infection, instrumentation.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.

Viral infection:
- Typically seen in immunocompromised patients after BMT.
- May present dramatically, but usually resolves spontaneously in ~2 wk.
- Other infections rarely cause severe HC.
- – Bacterial: E. coli, Enterococcus.
- – Prophylaxis: – Acute infections.
- – Can occur as late as 15–20 yr after exposure.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.

Medications:
- Typically seen in immunocompromised patients after BMT.
- May present dramatically, but usually resolves spontaneously in ~2 wk.
- Other infections rarely cause severe HC.
- – Bacterial: E. coli, Enterococcus.
- Systemic hematologic disease: Rare; often refractory to fulguration and irrigation.
- Systemic amyloidosis associated with rheumatoid arthritis or CREST disease.
- – Chemical toxic: – Acute, subacute, and chronic hematuria.
- – Systemic hematologic disease: Rare; often refractory to fulguration and irrigation.
- – Systemic amyloidosis associated with rheumatoid arthritis or CREST disease.
- Chemical toxic: – Acute, subacute, and chronic hematuria.

- Penicillin, piperacillin, methicillin, carbenicillin, nonoxynol-9 contraceptive.
- – Prophylaxis: – Acute infections.
- – Can occur as late as 15–20 yr after exposure.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.

- Penicillin, piperacillin, methicillin, carbenicillin, nonoxynol-9 contraceptive.
- – Prophylaxis: – Acute infections.
- – Can occur as late as 15–20 yr after exposure.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.

- Penicillin, piperacillin, methicillin, carbenicillin, nonoxynol-9 contraceptive.
- – Prophylaxis: – Acute infections.
- – Can occur as late as 15–20 yr after exposure.
- – Acute episodes wane within 12–18 mo.
- – Can recur as late as 15–20 yr after exposure.
Consider the following after all conservative modalities have failed, and patient is unstable.

- Adverse effects: Reflux could cause ureteral fibrosis and obstruction or papillary necrosis; vasoconstriction and platelet aggregation always be readily available.
- High rate of recurrence.
- Selective hypogastric artery embolization:
  - Stabilizes membranes, decreasing edema; causes vasoconstriction and platelet aggregation.
  - Adverse effect: Build-up can clog catheters.
  - Duration of response is often short.
- Hyaluronic acid:
  -  30 mL 100% phenol in 30 mL of glycine for 1 min, followed by saline flush.
  - May need repeat cystoscopy for hemorrhagic radiation cystitis.
  - May need surgical reconstruction.
- Phenol instillation:
  - 0.5–1% solution in bladder for 10–20 min, followed by saline flush.
  - Very painful, requires anesthesia.
  - Duration of response is often short.
- Prostaglandin instillation:
  - 5 mg/kg in 60 mL of 0.9% NaCl intravesical over 15 min.
  - Duration of response is often short.
- Aminocaproic acid (Amicar):
  - 0.25–0.5 g/kg per day for 5–7 days.
  - Low morbidity: No anesthesia required, no renal absorption.
  - Low success, as most bleeding is venous.

**COMPLICATIONS**

- Vesicoureteral reflux resulting from bladder fibrosis.
- Secondary UTIs from prolonged catheterization.
- Anemia, renal failure.
- Long term increases risk of secondary urothelial malignancy.
- Hyperbaric oxygen (4): Promotes granulation tissue and neovascularization, causes vasoconstriction.
- Higher rate of recurrence.
- Better for radiation-induced cystitis.
- Ureteral obstruction.
- Complications: Global classification, bladder necrosis, lower limb paralysis, anticoagulation.
- Low-lying branches of hypogastric artery.
- Low-dose cidofovir (3):
  - Low-dose cidofovir (3): 5 mg/kg in 60 mL of 0.9% NaCl intravesical over 15 min.
  - Duration of response is often short.
- Prostaglandin instillation:
  - 5 mg/kg in 60 mL of 0.9% NaCl intravesical over 15 min.
  - Duration of response is often short.
- Hyaluronic acid:
  -  30 mL 100% phenol in 30 mL of glycine for 1 min, followed by saline flush.
  - May need repeat cystoscopy for hemorrhagic radiation cystitis.
  - May need surgical reconstruction.
- Phenol instillation:
  - 0.5–1% solution in bladder for 10–20 min, followed by saline flush.
  - Very painful, requires anesthesia.
  - Duration of response is often short.
- Prostaglandin instillation:
  - 5 mg/kg in 60 mL of 0.9% NaCl intravesical over 15 min.
  - Duration of response is often short.
- Aminocaproic acid (Amicar):
  - 0.25–0.5 g/kg per day for 5–7 days.
  - Low morbidity: No anesthesia required, no renal absorption.
  - Low success, as most bleeding is venous.

**ADDITIONAL TREATMENT**

**Radiation Therapy**

- Contralateral, a recognized cause of HC.

**Additional Therapies**

- Hypertonic saline.
  - Promotes granulation tissue and neovascularization, causes vasoconstriction.
  - Better for radiation-induced cystitis.
  - Requires a hypertonic chamber, which may not always be readily available.
  - May require 30–40 daily treatments.
- Polyoma Virus (BK, JC), Urologic Consideration
- Cytoxan (Cyclophosphamide) Toxicity
- Radiation Therapy
- Radiation) Image
- Polyoma Virus (BK, JC), Urologic Consideration

**CODES**

- ICD9: 595.89 Other specified types of cystitis
- ICD10: N30.91 Cystitis, unspecified with hematuria
- N30.90 Cystitis, unspecified without hematuria
- N30.89 Other specified types of cystitis

**CLINICAL/SURGICAL PEARLS**

Optimum treatment for chemotherapy-induced HC is prevention (aggressive hydration and/or prophylactic mesna therapy).
CYSOTOCELE
Alana M. Murphy, MD

ASSOCIATED CONDITIONS
- Multicompartment POP
  - Always suspect concurrent apical prolapse in the setting of stage ≥3 cystocele
- Storage symptoms/signs: Stress UI, urinary urgency, urgency urinary incontinence (UI)
- Voiding symptoms/signs: Weak urinary stream, urinary hesitancy, elevated postvoid residual (PVR)
- Related to bladder outlet obstruction, urinary retention

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- No lab testing is required for the diagnosis of a cystocele
  - Urinalysis and urine culture as indicated
Imaging
- No imaging is required for the diagnosis or management of a cystocele
  - A cystocele may inadvertently be detected on imaging studies, such as a cystogram
  - Dynamic magnetic resonance imaging (MRI) with contrast
    - Evaluates pelvic structures in relation to one another during a Valsalva maneuver
    - Aids in differentiation between a cystocele and an enterocele
    - Aids in assessment of multicompartment POP

Diagnostic Procedures/Surgery
- Pelvic exam
  - Employ standardized staging system (POP-Q or Baden-Walker)
  - PVR assessment
  - Urinalysis
  - Only indicated to characterize associated storage and voiding symptoms/signs

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Cystocele
- Enterocele
- Anterior vaginal wall masses: Urethral diverticulum, Skene gland cyst, epidermal inclusion cyst, cesophageal, Bartholin duct cyst, Gartner duct cyst

TREATMENT
GENERAL MEASURES
- Observation
- Pelvic floor exercises (Kegel exercises) (E/R)
- Vaginal pessary
- Surgical repair

MEDICATION
First Line
- There are no data to support systemic or topical estrogen or other medications as a therapy for the treatment of cystoceles

Second Line
N/A

BASICS
DESCRIPTION
- Cystocele is prolapse of the bladder into the vagina
- Also referred to as anterior compartment prolapse

EPIDEMIOLOGY
Prevalence
- Difficult to determine due to several factors:
  - Data mostly reported in the context of surgical treatment
  - Cystocele may be asymptomatic
- Diagnosis requires a vaginal exam
- POP quantification (POP-Q) distribution in an observational study of women 18–82 yr old seeking routine gynecologic care (2):
  - POP-Q stage 0: 6.4%
  - POP-Q stage 1: 43.9%
  - POP-Q stage 2: 47.7%
  - POP-Q stage 3: 2.6%

RISK FACTORS
- Increasing age
- Family
- Vaginal delivery (nerve, muscle, and connective tissue damage)
  - Instrumented vaginal delivery may be associated with a higher risk of POP compared to spontaneous vaginal delivery
- Race (3):
  - Hispanic women have highest prevalence of POP
  - Increased intra-abdominal pressure (obesity, chronic cough, constipation)
- Pelvic surgery (hysterectomy, radical cystectomy)
- Congenital connective tissue disorders (Ehlers–Danlos syndrome)

Genetics
- Connective tissue disorders, bladder exstrophy
- POP prevalence rates differ according to race suggesting a genetic component (3)

PATHOPHYSIOLOGY
- Weakness of supporting and suspending structures:
  - Cardinal ligaments, uterosacral ligaments, endopelvic fascia, pubocervical fascia, levator ani muscles
- Defect locations:
  - Central: Attenuation of the pubocervical fascia in the midline
  - Lateral: Disruption of lateral attachments of the endopelvic fascia to the arcus tendineus fascia pelvis (ATFP)
- Combined defects

ASSOCIATED CONDITIONS
- Multicompartment POP
  - Always suspect concurrent apical prolapse in the setting of stage ≥3 cystocele
- Storage symptoms/signs: Stress UI, urinary urgency, urgency urinary incontinence (UI)
- Voiding symptoms/signs: Weak urinary stream, urinary hesitancy, elevated postvoid residual (PVR)
- Related to bladder outlet obstruction, urinary retention

DIAGNOSIS
HISTORY
- Symptoms/signs: Pelvic pressure, vaginal pressure, sensation of a vaginal bulge, stress/urgency/overflow UI, obstructive voiding symptoms, recurrent urinary tract infections (UTIs)
- Previous pelvic/vaginal surgical procedures
- Hormonal status
- Obstetric history
- Comorbidities

PHYSICAL EXAM
- Assessment of POP should be performed during a Valsalva maneuver
- Leading edge of POP should be used for staging purposes
- Examining a patient in a standing position may help determine the maximum extent of POP
- Assessment of the anterior compartment should be performed with support of the apical and posterior compartment to ensure the elimination of potentially distracting apical and posterior POP

BADEN–WALKER GRADING SCALE
- Grade 0: No POP
- Grade 1: Leading edge descends halfway to the hymen
- Grade 2: Leading edge descends to the hymen
- Grade 3: Leading edge descends halfway past the hymen
- Grade 4: Procidentia or vault eversion

POP-Q STAGING SYSTEM
- Stage 0: No POP
- Stage 1: Leading edge is between 1 cm above and 1 cm below the hymen
- Stage 2: Leading edge is <1 cm below the hymen but not less than total vaginal length – 2 cm (TVL – 2 cm)
- Stage 3: Leading edge is below hymen by more than TVL – 2 cm
**ADDITIONAL TREATMENT**

**Radiation Therapy**

N/A

Additional Therapies

- Observation
  - Appropriate if a patient is not symptomatic
  - Close to 30% of women will require reoperation for symptomatic POP (1)

- Pelvic floor exercises (Kegel exercises) (4)[B]
  - Good option for poor surgical candidates
  - May be used as a temporary solution
  - Risk of vaginal discharge, vaginal ulceration, vestibulovaginal fissure formation

**Complementary & Alternative Therapies**

N/A

**ONGOING CARE**

**PROGNOSIS**

- Recurrence rates as high as 30–70%
- Close to 35% of women will require reoperation for symptomatic POP (1)

**COMPLICATIONS**

- Blood loss
- Urinary injury/obstruction
- Bladder
- Dysesthesia
- de novo stress UI
- Recurrent cystocele

**FOLLOW-UP**

**Patient Monitoring**

Evaluation for recurrent POP should largely be based on symptoms or clinical signs (elevated PVR, urinary retention, recurrent UTIs)

**Patient Resources**

- American Urogynecologic Society.

  - 618.02 Cystocele, lateral

- ICD10
  - N81.10 Cystocele, unspecified
  - N81.11 Cystocele, midline
  - N81.12 Cystocele, lateral

**CLINICAL/SURGICAL**

- Management of a cystocele should largely be based on patient preference and symptoms.
- Always suspect concomitant apical prolapse in the setting of stage ≥3 cystocele or a recurrent cystocele.
- Mesh grafts for cystocele repair provide a superior anatomic outcome but they are associated with higher complication rates.
DEEP VENOUS THROMBOSIS AND PULMONARY EMBOLUS, UROLOGIC CONSIDERATIONS

Joshua D. Roth, MD
Michael O. Koch, MD, FACS

BASICS

DESCRIPTION

Deep vein thrombosis (DVT): Aggregation of platelets and fibrin within a deep vein of the leg or pelvic that may lead to venous obstruction.

Pulmonary embolism (PE): Blockage of the pulmonary artery or one of its branches by a thrombus that has traveled from elsewhere in the body through the bloodstream. Can be an acute life-threatening illness.

Genetics

- Inherited risk factors for DVT/PE (3):
  - Family history
  - Factor V Leiden mutation
  - Protein C deficiency
  - Protein S deficiency
  - Antithrombin deficiency
  - Sickle cell trait

PHYSIOLOGY

- Most PEs arise from DVTs:
  - Hypercoagulability: Regional activation of coagulation cascade leading to obstruction, edema, pain
  - Static: Stagnant hypoxemia causes endothelial injury
  - Injury: Platelet accumulation and fibrin deposition
  - Need to differentiate from superficial thrombophlebitis/thrombosis that does not usually lead to DVT

ASSOCIATED CONDITIONS

- Paradoxical embolism: Systemic embolisms of venous origin that occur in patients with atrial or ventricular septal defects, which allow the embolus to pass into the arterial circulation

GENERAL PREVENTION

- DVT prophylaxis (pPx):
  - Mechanical (nonpharmacologic) therapies
    - Early postoperative ambulation
    - Graduated compression stockings (GCSs)
    - Intermittent pneumatic compression (IPC)
  - Pharmacologic therapies
    - Subcutaneous low-molecular-weight heparin (LMWH)
    - Subcutaneous low-dose unfractionated heparin (LDUH)

- Recommendations (4):
  - High-risk patients who are at high risk for bleeding complications:
    - LMWH/LDUH (B), or mechanical pPx, preferably with IPC (C)
  - Moderate-risk surgery (VTE risk 0.5–3.0%):
    - LMWH/LDUH (B) or mechanical pPx, preferably with IPC (C)
  - Low-risk surgery (VTE risk <0.5%):
    - No specific pharmacologic (B) or mechanical (C) pPx

IMAGING

- Recent high-risk surgery, or other risk factors for VTE:
  - History of prolonged immobilization, postoperative status, especially in patient with risk factors
  - Complaint of calf pain, swelling, or discoloration
  - High clinical suspicion with above history
  - Acute onset of dyspnea, tachycardia, arrhythmia, hypotension

LAB

- D-dimers: Sensitivity approaches 95% for ELISA method
  - PE: ~80 mm Hg
  - ALB: Increased PA–aO2 gradient
  - D–dimer: >80 mg/dL

DIAGNOSTIC TESTS & INTERPRETATION

- Grayscale US to visualize the structure of the veins and color Doppler US to visualize the flow of blood through the vein; more accurate than Doppler and phlebography

108
DEEP VENOUS THROMBOSIS AND PULMONARY EMBOLUS, UROLOGIC CONSIDERATIONS

**MEDICATION**

**GENERAL MEASURES**
- Thrombi are a woven congealed mass of fibrin and platelets.
- Overall management of anticoagulation and antiplatelet therapy can be found in Section VII: Reference Tables: Anticoagulation and Antiplatelet Therapy in Urologic Practice

**DVT**
- Extremity elevation, early ambulation, pain relief
- If necessary LMWH therapy can be followed by unfractionated heparin

**PE**
- Pneumonitis/pneumonia, pneumothorax, CHF, DVT: Cellulitis, thrombophlebitis, muscle destruction of valves leads to chronic pain, swelling, skin necrosis, ulceration

**TREATMENT**

**ALERT**
- DVT and PE are potentially life-threatening and acute decline in status can occur. This condition must be treated/diagnosed quickly and level of suspicion must always be high in postoperative patients.

**GENERAL MEASURES**
- DVT: Extremity elevation, early ambulation, pain relief
- PE: Oxygen therapy, fluid resuscitation, maintain cardiac output with pressures if needed
- Overall management of anticoagulation and antiplatelet therapy can be found in Section VII: Reference Tables: Anticoagulation and Antiplatelet Therapy in Urologic Practice

**MEDICATION**

**First Line**
- DVT proximal to knee anticoagulation with (4):
  - Unfractionated heparin (UFH)
  - Fondaparinux
- Early mobilization of oral warfarin, with continued parenteral anticoagulation until INR is reached for >24 hr.
- DVT Distal to knee
  - Without severe symptoms/factors: Serial noninvasive imaging for 2 wk or anticoagulation (C). If thrombus extends, recommend therapeutic anticoagulation (B/C).
  - With severe symptoms/factors: Anticoagulation (as above) over imaging (C).
- PE
  - Systemic anticoagulation as for DVT (B/C)
  - PE with hypoxemia: Systemic thrombolysis with streptokinase is recommended (C).

**Second Line**
- DVT/PE
  - In patients with hepatic insufficiency thromboprophylaxis (HVT), UAW (argatroban, lepirudin, and danaparoid) can be used

**SURGERY/OTHER PROCEDURES**
- DVT
  - Venous thromboembolism: Rarely needed
  - SVC filter
    - Used as prophylaxis in high-risk or multitrauma patients
    - Recommended for acute DVT with contradi-
      ction to anticoagulation (4/B)
  - PE
    - Pulmonary emboloscopy: Considered rarely for patient who remains in shock despite medical therapy

**ADDITIONAL TREATMENT**

**Therapy**
- N/A

**Additional Therapies**
- Will need 3 mo of anticoagulation therapy for postsurgical DVT/PE
  - Prostakon can reverse unfractionated heparin if needed. Protamine is not as effective with LMWH but should be used if excessive bleeding is encountered

**Complementary & Alternative Therapies**
- N/A

**ONGOING CARE**

**PROGNOSIS**
- 10–30% of all patients with VTE suffer mortality within 30 days (3)
- Following anticoagulation therapy, 1/3 of all VTE patients will experience a recurrence within 10 yr (3)
- Highest risk of recurrence is in the 1st year (3)
- 1/3–1/2 of those with LE DVTs develop postthrombotic syndrome (3)

**COMPLICATIONS**
- DVT: Pulmonary embolism and postthrombotic syndrome: Destruction of valves leads to chronic pain, swelling, skin necrosis, ulceration
- PE: Death, pulmonary infarction, pain, atrhythmia, shortness of breath
- VTE: Requires anticoagulation with its associated risk factors (increased bleeding risk), increased healthcare costs, prolonged hospitalization, rehospitalizations
- Heparin-induced thrombocytopenia with unfractionated heparin

**FOLLOW-UP**

**Patient Monitoring**
- Patients on heparin: Follow aPTT
- If necessary LMWH therapy can be followed by antifactor Xa assays
- Patients on warfarin need close monitoring of their INR for a goal between 2.0 and 3.0 (3/B)

**Patient Resources**
- The Coalition to Prevent Deep-Vein Thrombosis
  - http://www.preventdvt.org
- The National Blood Clot Alliance

**REFERENCES**

**ADDITIONAL READING**

See also (Topic, Algorithm, Media)
- Reference Tables: Anticoagulation and Antiplatelet Therapy in Urologic Practice
- Deep Venous Thrombosis and Pulmonary Embolism, Urologic Considerations Image
- Deep Venous Thrombosis, Prophylaxis, AUA Guidelines

**ICD9**
- 415.10 Acute venous embolism and thrombosis of unspecified deep vessels of lower extremity
- 415.11 Iatrogenic pulmonary embolism and deep venous thrombosis, not elsewhere classified
- 453.40 Acute venous embolism and thrombosis of unspecified deep veins of lower extremity
- 997.2 Peripheral vascular complications, not elsewhere classified

**ICD10**
- I26.99 Other pulmonary embolism without acute cor pulmonale
- T81.72XA Complication of vein following a surgical procedure, NEC, init

**CLINICAL/SURGICAL PEARLS**
- Prophylaxis can help prevent DVT/PE
- PE usually develops from a venous thrombus involving the proximal lower extremity
- Early diagnosis and treatment are key.
DETRUSOR OVERACTIVITY
Lysanne Campeau, MD, CM, PhD, FRCSC
Victor W. Nitti, MD, FACS

PATHOPHYSIOLOGY
- Increased connectivity and excitability between detrusor muscle and nerves
- Inflammation
- Increasedafferent activity
- Neurologic lesions of the CNS above the sacral micturition center

ASSOCIATED CONDITIONS
- DO, pelvic floor disorders, urinary incontinence, bladder outlet obstruction, neurologic lesions above the sacral micturition center, detrusor external sphincter dyssynergia

GENERAL PREVENTION
- Avoiding large fluid intake or the consumption of “bladder irritants” such as caffeine.
- Timed voiding and avoiding bladder overdistension

DIAGNOSIS

ALERT
DO, by definition can only be diagnosed by urodynamic testing. Therefore it is not practical to talk in terms of diagnosing DO.

HISTORY (3)
- Past medical and surgical history
- Medications (diuretics, psychoactive drugs)
- Lower urinary tract symptoms survey
- Women with DO and OAB:
  - Are twice as likely to have urge urinary incontinence.
  - Have a higher symptom score on questionnaires
  - Higher episodes of daytime voiding and nocturia
  - Have lower functional bladder capacities
- Higher episodes of daytime voiding and nocturia
- Higher symptom scores on questionnaires
- Women with OAB:
  - Have lower functional bladder capacities

PHYSICAL EXAM
- Rule out the presence of exacerbating conditions
- Pelvic and vaginal exam
- Neurologic exam: Peripheral sensation and motor assessment
- Postvoid residual

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis: Determine presence of infection, hematuria, glycosuria
- Urine culture: Rule out infection
- Urine cytology: Rule out malignancy

Surgical
- Diagnostic Procedures/Surgery
  - Urodynamic testing
  - Filling cystometry: Measurement of the pressure/volume relationship of the bladder during filling

Imaging
- Can involve urodynamic testing with cystogram and voiding cystourethrogram
- Renal ultrasound can also rule out the presence of hydronephrosis caused by high bladder pressures

Pathologic Findings
DO is characterized by the presence of contractions that produce a wave form on urodynamic testing of variable duration and amplitude

DIFFERENTIAL DIAGNOSIS
- Bladder calculus
- Bladder cancer/tumor in situ
- Bladder outlet obstruction/Prostatic hypertrophy
- Congestive heart failure
- Detrusor external sphincter dyssynergia
- Diabetic neuropathy
- Interstitial cystitis/Painful bladder syndrome
- Medications
- Neurogenic bladder
- Pelvic organ prolapse
- Polyuria/polydipsia
- Sexually transmitted infection
- Stress incontinence
- Testing artifacts during UDS evaluation (false positive)
- Urinal tract infection
- UTI

GENERAL MEASURES
- Treatment aimed at inhibiting involuntary detrusor contractions and decreasing vesical pressures
- There are a number of options used to treat symptoms associated with DO. Only antimuscarinics, biofeedback, and augmentation cystoplasty have been proven to actually reduce or eliminate DO
- Behavioral modifications: Timed voiding, decrease fluid intake, avoid caffeine
- Pelvic floor exercises (Kegels): With or without biofeedback
DETRUSOR OVERACTIVITY

MEDICATION
- Antimuscarinics: Inhibit the effect of acetylcholine at postjunctional muscarinic receptors on detrusor muscle cells
  - Tolterodine (2–4 mg/d)
  - Trospium XR (60 mg/d)
  - Solifenacin (5–10 mg/d)
  - Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d, patch twice weekly)
  - Fesoterodine (4–8 mg/d)
- β3-adrenergic receptor agonist: Promotes detrusor muscle relaxation
  - Intravesical botulinum toxin (OnabotulinumtoxinA) injection
  - Sacral neuromodulation: Stimulation of S3 nerve root (InterStim)
  - Posterior tibial nerve stimulation (PTNS): Urgent PCTM
- Augmentation cystoplasty/Urinary diversion: Increase functional bladder capacity and reduce intravesical pressure
- Pelvic floor reconstruction: If concomitant pelvic floor disorder

FOLLOW-UP
- Patient Monitoring
  - Periodic patient follow-up
  - Symptom assessment
  - Treatment compliance
  - Minimize medication side effects

Patient Resources
- National Association for Continence: www.nafc.org/bladder-health

REFERENCES

ADDITIONAL READING

ONCOLOGIC/SURGICAL PEARLS
- OAB is not synonymous with detrusor overactivity, the key symptom of OAB is urinary urgency.
- DO demonstrated on cystometry needs to be correlated with patient’s symptoms.
- Treatment indicated if potential complications or patient driven.
- Only antimuscarinics, botulinum toxin, and augmentation cystoplasty have been proven to actually reduce or eliminate DO.

ADDITIONAL THERAPIES
- Infection prophylaxis
- Clean intermittent catheterization
- Decrease bladder pressure if urinary retention present

Ongoing Care
- Stepwise approach to treatment with least invasive pharmacologic options as first line
- May develop refractory OAB that may require second- or third-line treatment

FOLLOW-UP
- Periodic patient follow-up
- Symptom assessment
- Treatment compliance
- Minimize medication side effects

Patient Resources
- National Association for Continence: www.nafc.org/bladder-health

REFERENCES

DETRUSOR SPHINCTER DYSSYNERGIA (DSD)
Michael J. Amirian, MD
Patrick J. Shenot, MD, FACS

BASICS
DESCRIPTION
- Detrusor sphincter dyssynergia (DSD) is found in cases of neurogenic lower urinary tract dysfunction
- DSD is contraction of the sphincter mechanism occurring simultaneously with uninhibited involuntary contraction of the bladder detrusor muscle (neurogenic detrusor overactivity [NDO])

EPIDEMIOLOGY
Incidence
- Unknown
  - Depends on incidence of underlying neurologic condition
Prevalence
- Prevalent in those with spinal cord lesions
  - More prevalent at higher levels (cervical) than lower (sacral) injury or disease
- May affect those with multiple sclerosis (MS), spinal cord tumor, traumatic spinal cord injury (SCI), arteriovenous malformation
- Unilateral involuntary detrusor contraction (ie, NDO) must be present for DSD to occur

RISK FACTORS
- Neurologic processes affecting central nervous system (CNS)
  - Below level of the pons
- Associated with autonomic hyperreflexia

GENETICS
None

PATHOPHYSIOLOGY
- DSD causes functional outflow obstruction
- DSD causes chronic detrusor overactivity
  - Damaged elevation of intravesical pressure
  - Damaged urethral sphincter tone
  - Damaged urethral sphincter function
  - Nonrelaxing stenotic urothelial obstruction
  - Impaired transmission of coordinating influences from the pons during reflex detrusor contraction
- Uninhibited detrusor contraction stimulates a reflex sphincter contraction, resulting in bladder outflow obstruction
- 10–20% patients have internal (bladder neck) sphincter dyssynergia coexistent with external sphincter dyssynergia

ASSOCIATED CONDITIONS
- SCI
- MS
- Transverse myelitis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Neurologic disease
  - Date of onset, duration of process
- Urinary voiding symptoms
  - Frequency, urgency, urge incontinence
- Method of urinary management
  - Condom catheter urinary collection
  - Intermittent self-catheterization
- Indwelling urethral suprapubic catheter
- Urinary tract infection (UTI)
  - Severity of infection
  - Response to antibiotics
  - Need for parenteral antibiotics
  - Frequency of occurrence of infection
  - Urinalysis
  - Episodes of UTI
- Surgical intervention

PHYSICAL EXAM
- Fever
- Parenteral UTI
  - Men
  - Prostate, testes/epididymis, renal
  - Female
  - Pelvic
  - Hypertension
- Hypertension
  - During manipulation of GU/GI systems, autonomic hyperreflexia may result
  - Generalized edema
  - Sexual renal insufficiency
  - Filial rectal mass
  - Secondary hydrominosis
  - Flank tenderness
  - Ureteral obstruction
  - Pelvitis
  - Abdominal mass
  - Distended bladder, urinary retention
  - Incontinence of urine
  - Spontaneously
  - With stress maneuvers
  - During abdominal/pelvic palpation
  - With stress maneuvers
  - During abnormally high palpation
  - Testicular mass
  - Epidydymitis-orchitis/epididymitis
  - Secondary abscess formation
  - Hydrocele from recurrent infection
  - Prostate mass/Node
  - Prostatic prostatitis
  - Prostate abscess

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Blood studies
  - Serum chemistry
  - Renal function, electrolyte levels
  - Complete blood count
  - Secondary anemia due to decreased renal function or chronic infection
- Urine studies
  - Urinalysis
  - Proteinuria: Renal dysfunction
  - Pyuria, nitrite, leukocyte esterase: Acute or chronic infection
  - Hematuria: Infection or lithiasis

Imaging
- Renal ultrasound (US)
  - Effective in screening for upper urinary tracts
  - Calculi
  - Hydroureteronephrosis
  - Masses
  - Sonography (USG)
  - Contraindicated in those with decreased renal function (serum creatinine > 2.0)
- Delayed secretion of contrast with high urinary storage pressures
  - Hydroureteronephrosis
  - Marked elevation of intravesical pressure
  - May be due to urinary calculi
  - Voiding cystourethrogram
  - Bladder
    - Wall thickening
    - Trabeculation
    - Shuntreflux
    - Incomplete emptying
    - Ultrasound
      - Vesicoureteral reflux
      - Hydrocele
      - Hydroureteronephrosis
      - Ureteral
        - Prostatic urethral dilatation
        - Membranous urethra persistently narrow, stenotic, constricting
        - Distal urethra normal
        - Rule out stricture
        - Nuclear medicine renal scan
          - Objective quantification of GFR
          - Sequential studies can detect deterioration of renal function prior to elevation of serum creatinine
  - Diagnostic Procedures/Surgery
  - Ultrasound evaluation
    - Essential to diagnose detrusor overactivity with detrusor sphincter dyssynergia
  - Cystoscopy
    - Normal galea urethral
    - Spanning, nonrelaxing, stenotic membranous urethral
    - Dilated prostatic urethra
    - Bladder trabeculation/external trabeculation
    - Rule out calculus or bladder tumor

Pathologic Findings
None
DIFFERENTIAL DIAGNOSIS
- Detrusor instability and bladder outflow obstruction
- Bony prostatic hypertrophy
- Adenocarcinoma of the prostate
- Urethral stricture disease
- Urinary retention
- Impaired detrusor contractility
- Detrusor areflexia
- Urinary retention/incomplete emptying and neurogenic disease
- Decrease intravesical pressure
- Decrease bladder contractility
- Detrusor areflexia
- Urethral tumor
- Adenocarcinoma of the prostate
- Urethral stricture disease
- Neurogenic bladder
- Kyphoscoliosis

TREATMENT
GENERAL MEASURES
- Intermitent catheterization
- Decrease intravesical pressure
- Decrease bladder contractility
- Detrusor areflexia
- Decrease urinary storage

MEDICATION
First Line
- Anticholinergic therapy
  - Effective in improving urinary storage under low pressure
  - Phosphodiesterase 5 inhibitors
  - β-Adrenergic blockade
  - α-Adrenergic blockade
- Endoscopic sphincter ablation
- Botulinum toxin injection into the external sphincter

Second Line
- Botulinum toxin injection into the external sphincter for DSD
- Adrenergic blockade
- Anticholinergic therapy
- Endoscopic sphincter ablation
- Botulinum toxin injection into the external sphincter

SPECIAL CONSIDERATIONS
- Urinary retention
- Detrusor areflexia
- Urethral stricture disease
- Neurogenic bladder
- Kyphoscoliosis

OTHER PROCEDURES
- Endoscopic sphincterotomy
- Electrosurgical or laser sphincterotomy
- Nerve root stimulation allows control over detrusor contraction
- Conduit of ileum connecting dome of bladder to anterior abdominal wall

Ongoing Care
- Excellent prognosis if effectively treated
- Uninked, ~50% of men will develop significant complication

COMPLICATIONS
- Detrusor instability
- Neurogenic bladder
- Urethral stricture disease
- Neurogenic bladder

DIABETES MELLITUS, UROLOGIC CONSIDERATIONS

Thomas M. Facelle, MD
Mark L. Jordan, MD, FACS

BASICS

DESCRIPTION
- Hyperglycemia with secondary metabolic abnormalities
- Two subtypes including insulin deficiency (DM1) and insulin resistance (DM2)

EPIDEMIOLOGY

Risk factors
- Genetic predisposition
- Environmental factors

Prevalence
- 8.3% of US population in 2010 was diabetic (1)

Incidence
- 30% with DM1 and 10–40% with DM2 will develop kidney failure
- 59% with DM will have urologic complications

Risk factors
- Genetics
  - Strong hereditary component for DM2
  - DM1: Approx one-third genetic contribution
- Environmental
  - Visceral obesity for DM2

DIAGNOSIS

History
- General
  - Polyuria, polydipsia
  - Weight loss, malaise
- Family history
- Previous DM
- Weight loss, malaise
- Polyuria, polydipsia

Physical Exam
- General
  - Symmetry, nodules, tenderness
  - Abdomen
  - Flank
  - External genitalia
  - Prostate
  - Rectal
- History
  - Infertility
  - Voiding dysfunction
  - UTI

Assessments
- Laboratory
  - Fasting glucose
  - Oral GTT, 2-hr value
  - Microalbuminuria
  - Uric acid
  - Erythrocyte sedimentation rate

DIFFERENTIAL DIAGNOSIS

- Bladder cancer
- Increased incidence and mortality seen in men and women with DM

ASSOCIATED CONDITIONS
- Obesity
- Metabolic syndrome
- Neuropathy
- Renal failure

GENERAL PREVENTION
- Glycemic control
- Weight reduction

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Urinalysis
- Urine culture, and sensitivities
- Microalbuminuria

DIFFERENTIAL DIAGNOSIS

- UTI
- Pyelonephritis
- Urinary tract infection
- Urinary tract obstruction
- Urinary tract infection
- Urethral stricture
- Neurogenic bladder
- Urethral stricture
- Neurogenic bladder
- Urethral stricture
- Neurogenic bladder
DIABETES MELLITUS, UROLOGIC CONSIDERATIONS

TREATMENT

GENERAL MEASURES
- Educate patients regarding urologic manifestations of diabetes
- Glycemic control
  - Dietary improvement, weight loss, exercise

MEDICATION

First Line
- UTI
  - DM is an underlying condition that makes any UTI a complicated UTI
  - Antibiotics (oral vs. intravenous)
  - Fluid resuscitation
- ED
  - Oral phosphodiesterase inhibitors (sildenafil, vardenafil, vardenafl, avanafil)
- Voiding dysfunction
  - α-blockers if outlet obstruction (benign)
  - Bladder stimulation (anticholinergic, cholinergic)
- Voiding dysfunction
  - α-blockers if bladder outlet obstruction (benign)
- UTI
  - Voiding dysfunction
  - α-blockers if bladder outlet obstruction
- Voiding dysfunction
  - α-blockers if bladder outlet obstruction
- ED
  - α-blockers if bladder outlet obstruction

Second Line
- ED
  - Intravesical suppository (MUSE)
- Voiding dysfunction
  - α-blockers if bladder outlet obstruction
- UTI
  - Voiding dysfunction
  - α-blockers if bladder outlet obstruction

SURGERY/OTHER PROCEDURES
- UTI
  - Retention: Catheter placement, suprapubic tube
  - Urolithiasis: Urine electrolytes, nephrostomy tube, ureteroscopy, extracorporeal shock wave lithotripsy
- ED
  - Penile prosthesis
- Voiding dysfunction
  - Cystoscopic resection (transurethral)- efficacy for overactivity and retention
- Bladder outlet obstruction: Trans urethral resection of prostate, photoselective vaporization of prostate, etc.
- Lower urinary diversion (urostomy, ileal conduit)
- Incontinence
  - Artificial urinary sphincter
- Bladder cancer
  - Transurethral resection, cystectomy

ADDITIONAL TREATMENT

Radiation Therapy
- ED
  - Radiation therapy
- Voiding dysfunction
  - Radiation therapy
- Erectile dysfunction
  - Vascular dysfunction

Complementary & Alternative Therapies

- UTI
  - Cranberry extract
- Voiding dysfunction
  - Acupuncture to sacral dermatome

ONGOING CARE

PROGNOSIS
- Good with tight glycemic control
- Late presentation and progression of symptoms

COMPLICATIONS
- UTI
  - Upper tract infection
  - Staphylococcus, KPC
- Renal failure
- Voiding dysfunction
  - UTI
- Upper tract damage/renal failure
- Incontinence
- Bladder stones
- Atonic bladder
- Diabetic nephropathy
  - ESRD
- Dialysis dependence

FOLLOW-UP

Patient Monitoring
- General
  - Periodic serum glucose
  - HbA1c
- Glycemic control
  - Urine protein and microalbuminuria
- ED
  - Testosterone replacement: Check serum testosterone, prostate specific antigen (PSA), renal function for eligibility
- Voiding dysfunction
  - Symptomatology
  - RU/PH/CT
- Incontinence
  - Repeat urodynamics as needed

Patient Resources
- Centers for Disease Control and Prevention, Diabetes Public Health Resource: http://www.cdc.gov/diabetes

- 585.7.1 E10.29 Type 2 diabetes mellitus w/oth diabetic kidney complication

ICD10
- E10.29 Type 1 diabetes mellitus woth diabetic kidney complication
- E11.29 Type 2 diabetes mellitus woth diabetic kidney complication
- N05.6 E10.29 Type 1 diabetes mellitus woth diabetic kidney complication
- N17.8 E10.29 Type 2 diabetes mellitus woth diabetic kidney complication
- N17.8.1 E10.29 Type 1 diabetes mellitus woth diabetic kidney complication

CLINICAL/SURGICAL PEARLS
- DM predisposes to urinary infections of greater severity with likely upper tract involvement.
- Most common voiding symptom is overactivity.
- ED may be the presenting sign of DM.
- Tight glycemic control is necessary to reduce progression of symptoms.
DISORDERS OF SEXUAL DEVELOPMENT (DSD)

Luigi Avolio, MD

BASICS

DESCRIPTION
- Congenital condition in which development of chromosomal, gonadal, or anatomic sex is atypical (1)
- Chromosomal sex is inconsistent with phenotypical sex
- DSD is the result of a discordance among the 3 sex determination processes (chromosomal, gonadal, and phenotypical)
- Ambiguous genitalia and intersex disorders are no longer considered correct terms
  - Classification
    - See chromosome DSD
    - XX DSD
    - XY DSD

EPIEDELOLOGY

Incidence
- 1 in 5,000 live births
  - Congenital adrenal hyperplasia (CAH) represents 60–70% of neonatal DSD (1 case per 15,000 live births)

Prevalence
- N/A

RISK FACTORS
- Family history of DSD
- In utero exposure to androgens
  - Dietary teratogens
  - Maternal injection

Genetics
- XX DSD
  - CF21-gene-ch1q13.13. Autosomal recessive
  - 3β-hydroxysteroid dehydrogenase deficiency, MIM#201910, 150822 genes-ch1.p2.1. Autosomal recessive
- XX DSD
  - P450 oxidoreductase deficiency, MIM#201910, 150822 genes-ch1.p2.1. Autosomal recessive
  - Persistence of mullerian duct syndrome (PMDS)

ASSOCIATED CONDITIONS
- Turner syndrome
- Klinefelter syndrome
- Rettinsen syndrome
- Inguinal hernia
- Congenital adrenal hyperplasia
- Amenorrhea
- Infertility

GENERAL PREVENTION
- Prenatal treatment of tissues at risk for CAH with dexamethasone
- Chorionic villus sample
- Amniocentesis

DIAGNOSIS

HISTORY
- Family anamnesis
  - DSDs, genital abnormalities, amenorrhea, sterility, hirsutism
  - Early infant deaths (missed adrenocortical syndrome)
- Maternal exposure to androgens
- History of maternal virilization (androgen-producing tumor)

PHYSICAL EXAM
- External genitalia
  - Phalic structure (length, breadth, and amount of erectile tissue)
- Abdomen
  - Mass referable to enlarged uterus

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Karyotype
- Serum levels of sodium, potassium, and 17hydroxyprogesterone
- Androgens (testosterone, dehydroepiandrosterone, androstenedione)
- Cortisol, gonadotrophins, and AMH levels
- Stimulation test with human chorionic gonadotropin (suspected defect of androgen production)
DISORDERS OF SEXUAL DEVELOPMENT (DSD)

Imaging
- Abdominal pelvic ultrasonography (renal presence)
- Cystogram/urogram (visualisation of vagina, lithotripsy)
- MRI

Diagnostic Procedures/Surgery
- Laparoscopy to define internal anatomy
- Cystoscopy to confirm anatomy and level of confluence of urogenital sinus
- Gonadal biopsy to analyse presence of ovarian and/or testicular tissue
- Skin biopsy to obtain cellular lines

Pathologic Findings
Identification of ovarian tissue, testicular tissue, ovotestes, or streak gonads according to related specific disorders

DIFFERENTIAL DIAGNOSIS
- Hypothyroidism
- Hypospadias
- Hydrocele and hernia
- Menstruation disorders
- Microphallus
- Gonadal dysgenesis

TREATMENT
GENERAL MEASURES
- Gender assignment avoiding hasty decision
- Expert evaluation by an experienced multidisciplinary team

MEDICATION
First Line
- Nifedipine with self-washing CAH
- Fluid and electrolyte replacement
- Glucocorticoid and mineralocorticoid replacement
- Hydrocortisone 10 mg/m2/d
- Fludrocortisone 0.1–0.2 mg/d
- Oral sodium chloride, 1–2 g/d added to formula or breast milk

Second Line
- Pseudoephedrine

SURGERY/OTHER PROCEDURES
- Masculinizing genitoplasty (between the ages of 6 and 18 mos)
  - Hormonal treatment with testosterone preparation to stimulate phallic development
  - Surgical excision of Müllerian structures
  - Phaloplasty (hypospadias repair, chordee correction, corporal transposition)
  - Orchidopexy
  - Rectal injury (urogenital sinus mobilization)
- Feminizing genitoplasty (during the 1st 6 mo of life)
- Clitoroplasty preserving innervation to reduce the size of the gland and shaft
- Vaginoplasty and labioplasty to separate vagina and urethra from the common urogenital sinus
- Gonads
  - 46XX DSD: Normal ovaries, no treatment necessary
  - 46XY DSD: Gonadal biopsy
  - Female gender assigned: Orchiectomy (timing is subject of debate)
  - Male gender assigned: Orchidopexy
  - Gonadal dysgenesis
- Exclusion of dysgenetic gonads (steak)

- Müllerian remnants
  - Small asymmetries are managed conservatively
  - Symptomatic remnants are treated surgically (endoscopic excision or unfolding, laparoscopic robotic excision)

ADDITIONAL TREATMENT
Radiation Therapy
No

Additional Therapies
No

Complementary & Alternative Therapies
No

ONGOING CARE
PROGNOSIS
Many patients can remain fertile (CAH, some ovotesticular DSD, XY DSD with X0)

COMPLICATIONS
- Acute adrenal insufficiency in CAH not adequately treated
- Damage to clitoral innervation (clitoroplasty)
- Steroid of the vaginal introitus (laparoplasty)
- Urinary obstruction (urogenital sinus mobilization)

FOLLOW-UP
Patient Monitoring
- Sexual function (adequate vaginal introitus, adequate penile reconstruction)
- Risk of gonadoblastoma in gonadal dysgenesis is 12% (occurrence of neoplasia is primarily associated with the Y chromosome containing karyotype)
- Lifetime psychosocial support mandatory for all patients with DSD

Patient Resources

- See Also (Topic, Algorithm, Media)
  - Androgen Insensitivity Syndrome (46,XY, Androgen Resistance Syndrome), Complete (CAIS) and Partial (PAIS)
  - Müllerian Duct Remnants and Persistent Müllerian Duct Syndrome (PMDS)
  - Pseudohermaphroditism, Male and Female

CODES

- ICD9
  - 259.80 Congenital adrenogenital disorders
  - 293.90 Androgen insensitivity, unspecified
  - 752.7 Intersex and reproductive defects
  - 756.4 Intersex and reproductive defects

- ICD10
  - E25.0 Congenital adrenogenital disorders associw engine deficiency
  - E34.50 Androgen insensitivity syndrome, unspecified
  - Q56.4 Intersex and reproductive defects

CLINICAL/SURGICAL PEARLS
- DSD should be managed by a specialized multidisciplinary team
- Gender assignment should be made after thorough investigation by the team
- DSD is a heterogeneous group of conditions with different underlying molecular causes. Many disease genes remain to be identified
- Infants with a DSD and who present with truly ambiguous genitalia are a rare occurrence.
DYSFUNCTIONAL ELIMINATION SYNDROME
Jennifer A. Hagerty, DO

BASICS
DESCRIPTION
- Dysfunctional voiding; various symptoms from mild daytime frequency and postvoid dribbling to daytime and nighttime wetting, urgency, urge incontinence, pelvic holding maneuvers, and urinary tract infections (UTIs)
- Sometimes referred to as bowel bladder dysfunction (BBD)
- Dysfunctional voiding often associated with bowel dysfunction; constipation, encopresis, or fecal impaction
- Constipation and rectal dilation interfere with normal bladder function
- No identifiable neurologic cause

EPIDEMIOLOGY
Incidence
- Constipation is present in up to 50% of children with dysfunctional voiding

Prevalence
- 20–30% school-aged children have dysfunctional voiding

RISK FACTORS
- UTIs
- Sexual abuse
- Attention deficit/hyperactivity disorder
- Stressors during or after toilet training

Genetics
- Ochoa syndrome, a genetic disorder with an autosomal recessive inheritance pattern
  - Associated with dysfunctional voiding

PATHOPHYSIOLOGY
- Voiding dysfunction (variable etiologies):
  - Small bladder capacity
  - Large bladder capacity secondary to urine holding
  - Disordinated voiding with difficulty relaxing the sphincter during voiding
  - Often associated with constipation
  - Rectum close to posterior wall of bladder
  - Large amount stool
  - Obstruction by compression of the bladder and bladder neck
  - Obstruction by compression of the bladder and bladder neck

ASSOCIATED CONDITIONS
- Vesicoureteral reflux (VUR)
- UTIs
- Encopresis
- Incontinence
- VUR
- Urge syndrome

GENERAL PREVENTION
- None have been identified

DIAGNOSIS
HISTORY
- Present typically after toilet training
- Diurnal and/or nocturnal enuresis
- Frequency and urgency
- Hegidity
- UTIs
- Difficulty stooling, hard or infrequent stools
- Encopresis

PHYSICAL EXAM
- Typically normal physical exam
  - Evaluate for neurologic dysfunction
  - Examine the external genitalia for anatomic causes of symptoms
  - Evaluate for a distended bladder and palpable stool
  - Consider rectal exam for fecal retention

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and urine culture; rule out bacteriuria and glucosuria

Imaging
- Renal/bladder ultrasound; evaluate for hydronephrosis, thickened and/or distended bladder, post-void residual, stool in the rectum
- MRI lumbar spine if concern for a neurogenic cause to evaluate for a tethered cord
- Voiding cystourethrogram to evaluate for VUR in patients with febrile UTIs.
  - Also information on bladder capacity and emptying, and appearance of the bladder and urethra
  - Spinning top urethra; widening of the urethra in females during voiding

Diagnostic Procedures/Surgery
- Voiding and stooling diary to assess frequency and volume of voids and stooling frequency and consistency
- Uroflowmetry evaluate pattern
  - Flow rates different than adults and less reliable; curve more diagnostic
  - Bell shaped—normal
  - Tower shaped—overactive bladder
  - Low flat curve—obturator obstruction
  - Staccato pattern—sphincter overactivity
  - Interrupted flow—underactive bladder
- Urodynamic; patients refractory to conventional therapy
  - Evaluate the filling and emptying phases of the bladder
  - Can be done in conjunction with fluoroscopy

DIFFERENTIAL DIAGNOSIS
- Nonneurogenic neurogenic bladder
- Neurogenic bladder
- Ochoa syndrome
- Overactive bladder
- Giggle Incontinence

TREATMENT
GENERAL MEASURES
- Behavioral modification: Education on voiding patterns
  - Timed voiding
  - Correct positions to void
  - Relaxation techniques
  - Proper hydration
  - Bowel management
  - Education on correlation between the bladder and bowel activity
  - Daily toilet time
  - Dietary modifications; high fiber

MEDICATION
First Line
- Treatment of constipation prior to medications for bladder symptoms; disimpaction followed by maintenance therapy
  - Initial treatment with laxatives and enemas
  - Maintain soft daily stools with a combination of fiber, fluids, laxatives, and softeners
DYSFUNCTIONAL ELIMINATION SYNDROME

- Antimuscarinics; overactive bladders
  - Reduce the intensity and frequency of bladder contractions
- α-Adrenergic blockers; bladder neck obstruction
  - Relaxation of the bladder neck to improve bladder emptying
- Prophylactic antibiotics; prevention of recurrent UTIs until dysfunctional elimination improved

Second Line
- Tricyclic antidepressants for urge incontinence
  - Mechanism not known; not FDA approved in children

SURGERY/OTHER PROCEDURES
- Biofeedback
- Transcutaneous electrical nerve stimulation

ADDITIONAL TREATMENT
Radiation Therapy
N/A

ADDITIONAL THERAPIES
Clean intermittent catheterization with impaired bladder contractility
Complementary & Alternative Therapies
- Acupuncture
  - Low utility in children given use of needles
- Probiotics, prevention of UTIs and treatment of constipation
- Cranberry supplements; potential for UTI prevention

ONGOING CARE
PROGNOSIS
Most children have resolution of symptoms in a short period of time with behavioral modifications; however, some children may have persistence requiring more intensive management.

COMPILATIONS
- UTIs
- Urinary incontinence
- Urinary retention
- Hydronephrosis

FOLLOW-UP
Patient Monitoring
- Voiding/stooling diary
- Uroflowmetry
- Post-void residual monitoring

Patient Resources

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Enuresis, Pediatric
- Incontinence, Urinary, Pediatric
- Urinary Retention, Pediatric
- Urinary Tract Infection, Pediatric
- Vesicoureteral Reflux, Pediatric
- Dysfunctional Elimination Syndrome Image

CODES
ICD9
- 599.0 Urinary tract infection, site not specified
- 788.3 Urinary incontinence
- 788.41 Urinary frequency

ICD10
- N39.0 Urinary tract infection, site not specified
- R32 Unspecified urinary incontinence
- R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARS
- Constipation is often associated with bladder dysfunction in children.
- Treatment of constipation alone may lead to complete resolution of urinary complaints.
- Vesicoureteral reflux may resolve after treatment of voiding dysfunction.
- Education of the correlation between stooling patterns and voiding complaints is a very important part of treatment; if understanding is poor there is often low compliance.

119
DYSORGASMIA (PAINFUL ORGASM), MALE
John Patrick Mulhall, MBCh, FACS, FECSM

BASICS

DESCRIPTION

• Dysorgasmia specifically refers to pain that occurs immediately preceding, at or immediately following orgasm.
• The pain is usually located in the penis or testicles but may be present in the lower abdomen, groin, perineum, or elsewhere.
• The severity of pain ranges from mild and of nuisance value to crippling and may last seconds to hours after orgasm.
• The condition is best identified and studied in the postradical prostatectomy setting.
• Ejaculatory pain may be seen in other conditions such as chronic prostatitis/chronic pelvic pain syndrome (CPPS), or NIH category III prostatitis, and is discussed in Section II (“Ejaculation, painful”).

EPIDEMIOLOGY

Incidence

• The most frequent correlate of dysorgasmia is radical prostatectomy and this condition occurs in about 10–15% of patients.
• In this population, the pain is usually self-limiting with most sufferers experiencing complete resolution by 2 yr postoperatively.

Prevalence

N/A

RISK FACTORS

• Radical prostatectomy
• Prostate radiation
• Chronic pelvic pain syndrome (CPPS)

Genetics

None known

PATHOPHYSIOLOGY

• While unproven one of the postulated mechanisms is that the pain is related to pelvic floor or bladder neck spasm.
• This is the rationale for the use of α-blockers.
• Dysorgasmia decreases in frequency and degree over time after RP.

ASSOCIATED CONDITIONS

• Chronic pelvic pain syndrome (NIH category III prostatitis)
• Erectile dysfunction (1)
• Prostate cancer

GENERAL PREVENTION

None known

DIAGNOSIS

HISTORY

• Medical history
• Focusing on assessment of orgasmic pain location, severity and duration.
• Prior history of radical prostatectomy, radiation therapy, or CPPS.

PHYSICAL EXAM

• General physical exam
• Genital exam (although often there are no specific findings)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

None are useful

Imaging

None are useful

Diagnostic Procedures/Surgery

None

Pathologic findings

None

DIFFERENTIAL DIAGNOSIS

• Pelvic pain:
  – Perineal compressive neuropathy
  – Perineal trauma
  – Perineal disease
  – Sexually transmitted infection (STI)
  – Urinary stone
• Testicular pain:
  – Epididymitis
  – Orchitis
  – Testicular tumor
  – Trauma

TREATMENT

GENERAL MEASURES

Reassurance that the condition is most often self-limiting

MEDICATION

First Line

• α-Blockers (daily initially; if successful attempt on-demand) (2)
• Up to 70% of men using α-blockers will have significant improvement in pain.
• Side effects include syncope, orthostasis, retrograde ejaculation, asthenia, and nasal congestion
  – Alfuzosin 10 mg/d
  – Doxazosin start 1 mg/d to max 8 mg
  – Silodosin 8 mg/d
  – Tamsulosin start 0.4 mg to max 0.8 mg
  – Terazosin start 1 mg/d to max 20 mg

Second Line

• Centrally acting pain relievers
• Optimum dose and duration not established
  – Gabapentin
  – 900 to 1,800 mg/d and given in divided doses (3 times a day) using 300 or 400 mg capsules
  – Pregabalin
  – Begin dosing at 150 mg/d, increase to 300 mg/d within 1 wk. Maximum dose of 600 mg/d

SURGERY/OTHER PROCEDURES

Cases reports exist of excision of retained seminal vesicle following radical prostatectomy with relief of symptoms (3)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A
DYSORGASMIA (PAINFUL ORGASM), MALE

ongoing care

PROGNOSIS
• Recovery is expected following radical prostatectomy.
• At 24 mo, a statistically significant decrease in symptoms was seen in one study (4).
  – 72%, 26%, and 7% of patients still complained of pain at 1, 18, and 24 mo, respectively.

COMPlications

FollOW-UP

Patient Monitoring
Routine radical prostatectomy follow-up appears most appropriate.

Patient Resources

RefErEnces

additional ReadiIng

• See also (Topic, Algorithm, Media)
  • Ejaculatory Disorders (Delayed, Decreased, or Absent)
  • Ejaculation, Painful
  • Post-organ Fibrosis Syndrome (POS)
  • Prostatitis, Chronic Nonbacterial, Inflammatory and Noninflammatory (NIH CP/CPPS III A and B)

cliniCal/Surgical pearlS

• Dysorgasmia is common after radical prostatectomy.
• It is usually self-limiting.
• It is often responsive to α-blocker therapy.

codes

ICD-9
• 607.89 Other specified disorders of penis
• 608.89 Other specified disorders of male genital organs
• 789.09 Abdominal pain, other specified site

ICD-10
• N48.89 Other specified disorders of penis
• N50.8 Other specified disorders of male genital organs
• N53.12 Painful ejaculation

clinical/surgical pearlS

• Dysorgasmia is common after radical prostatectomy.
• It is usually self-limiting.
• It is often responsive to α-blocker therapy.
DYSPAREUNIA, FEMALE
Bradley C. Gill, MD, MS
Sandip P. Vasavada, MD, FACS

BASICS

DESCRIPTION
Dyspareunia is defined as pain associated with sexual intercourse. Most often used in association with female sexual dysfunction and is the focus of this section.

- Present since 1st (primary) intercourse or acquired (secondary) thereafter.
- Etiologies can be physiologic and/or psychological.

Epidemiology
Incidence
Lack of disclosure to clinicians and treatment pursuit suggests underestimation

Prevalence
Up to 60% prevalence in women, but varies widely by sample and definition.

RISK FACTORS
- Menopause (physiologic or iatrogenic)
- Physical trauma (physiologic or iatrogenic)
- Psychological trauma (supporting evidence is mixed)
- Tissue irritation (infection, inflammation, malignancy, etc.)
- Urinary tract infection

Genetics
Early menopause should be considered

PATHOPHYSIOLOGY
- Pain results from irritation or trauma to the female urogenital anatomy (congenital)
- Etiologies can be physiologic and/or psychological.
- Present since 1st (primary) intercourse or acquired (secondary) thereafter.

ASSOCIATED CONDITIONS
- Vaginal atrophy
- Urinary conditions
- Pelvic inflammatory disease
- Systemic conditions
- Menopause (physiologic or iatrogenic)
- Other chronic diseases

GENERAL PREVENTION
- Maintenance of vaginal mucosal integrity
- Good hygiene and health maintenance

DIAGNOSIS

DESCRIPTION
Dyspareunia is defined as pain associated with sexual intercourse.

- Most often used in association with female sexual dysfunction and is the focus of this section.
- Present since 1st (primary) intercourse or acquired (secondary) thereafter.
- Etiologies can be physiologic and/or psychological.

HISTORY
- Description of pain
  - Positioning, specific maneuvers, location
  - Use of lubricants, condoms, sex toys, hygiene products
  - Specific partners or partner-related factors
  - Timing of menstrual cycle
  - Bowel or bladder habits
  - Urinogenital conditions
  - Sexually transmitted or urinary tract infections
  - Complicated pregnancies
  - Endometriosis
  - Uterine fibroids
  - Inflammatory bowel disease
  - Urinogenital trauma
  - Vaginal childbirth injuries
  - Difficult or forced intercourse
  - Systemic conditions
  - Menopause (physiologic or iatrogenic)
  - Pain disorders or fibromyalgia
  - Cancer
  - Other chronic diseases
  - Vaginal trauma
- Current or prior abuse
  - Sexual abuse
  - Verbal or physical abuse

PHYSICAL EXAM
- Visual inspection of external genitalia
  - Distribution of pubic hair
  - Diffuse vulvo-vestibular
  - Lacerations, puncture, discharge, bleeding
  - Inflamed Bartholin or Skene glands
  - Prolapsed urethra, vagina, or cervix
  - Skin or mucosal lesions suspicious for cancer
  - Speculum exam
    - Diffuse vaginitis or cervicitis
    - Mucosal rugae, moisture, thinning, or excoriation
  - Vaginal wall masses
  - Ulcerations, pustules, discharge, or bleeding
    - Diffuse vaginitis or cervicitis
    - Vaginal wall masses
    - Lacerations suspicious for cancer

Diagnostic sampling with cervical surface scrapings, brushings, and culture swabs
- Lacerations, punctures, or discharge
- Masses, skin changes, mucosal changes, bleeding
- Palpation of external genitalia, vaginal sidewalls, pelvic floor muscles, cervix, and ovaries
  - Bartholins or Skene gland tenderness
  - Urethral or vaginal sidewall mass
  - Surgically placed foreign bodies
  - Pelvic floor muscle tension, spasm, or tenderness
  - Cervical motion, ovulatory, or adrenal tenderness
  - Vaginal cul-de-sac mass or tenderness

FACTORS ALTERING THE PAIN
- Positioning, specific maneuvers, location
- Use of lubricants, condoms, sex toys, hygiene products
- Specific partners or partner-related factors
- Timing of menstrual cycle
- Bowel or bladder habits
- Urinogenital conditions
- Sexually transmitted or urinary tract infections
- Complicated pregnancies
- Endometriosis
- Uterine fibroids
- Inflammatory bowel disease
- Urinogenital trauma
- Vaginal childbirth injuries
- Difficult or forced intercourse
- Systemic conditions
- Menopause (physiologic or iatrogenic)
- Pain disorders or fibromyalgia
- Cancer
- Other chronic diseases
- Vaginal trauma
- Current or prior abuse
- Sexual abuse
- Verbal or physical abuse

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Urinalysis and urine culture to screen for infection or cystitis
  - Endometrial swabs for gonorrhea, chlamydia, or bacterial vaginosis
  - Cervical scrapings or brushings for malignancy and human papilloma virus
  - Vaginal pH, wet mount, or whiff test for bacterial or fungal infection

Imaging
- Transvaginal ultrasound for reproductive organ or pelvic masses
- Transabdominal ultrasound for abdominal masses
- Pelvic magnetic resonance imaging for uterine diverticula or pelvic masses

Diagnostic Procedures/Surgery
- Cystourethroscopy for cystitis, urethritis, urethral diverticula
- Double-balloon urethrography for urethral diverticula
- Colposcopy for human papilloma virus or uterocervical malignancies
- Colonoscopy for inflammatory bowel disease or colo-rectal malignancy
- Diagnostic laparoscopy for endometriosis or pelvic masses

DIFFERENTIAL DIAGNOSIS
- Congenital
  - Vaginal agenesis, vaginal malformation, imperforate hymen, sigil hymen, retroverted uterus
- Gynecologic
  - Structural: Hymenal remnant, introital or vaginal stenosis, polyps, childbirth, adhesions
  - Inflammatory: Vaginal atrophy, lichen sclerosus, vulvar lichen planus
  - Infectious: Sexually transmitted, viral, bacterial vaginosis, fungal, pelvic inflammatory disease
  - Allergic: Contact dermatitis, vulvar lichen planus, latex, semen, vaccine product, etc.
  - Reproductive: Endometriosis, fibroids, ectopic pregnancy, adenomatous cysts, ovarian cyst
  - Iatrogenic: Implant erosion, exposed sutures, postoperative fistula

Urologic
- Urinary prolapse, urethral carcinoma, urethral diverticulum, urethral cancer, urethritis, cystitis
- Colorectal
  - Inflammatory bowel disease, abscess, hemorrhoids, constipation, rectal cancer
- Musculoskeletal
  - Vaginismus, pelvic floor muscle spasm, trauma, chronic pain disorder, fibromyalgia

Psychological
- Posttraumatic stress disorder, sexual aversion disorders, genital sexual arousal disorder
TREATMENT

GENERAL MEASURES
- Behavioral (1,2)
  - Identify and eliminate any allergy-related hygienic or sexual practices
  - Encourage using water-based lubrication or hypoallergenic products
- Use infection prophylaxis like postcoital voiding when appropriate for UTI issues
- Psychological counseling, couples therapy, or relaxation exercises as indicated
- Careful consideration of replacing condoms or other barrier devices with another contraceptive

MEDICATION

First Line
- Trigger point injections for muscle spasm
- Excision of implanted mesh, eroded sutures, or other foreign body
- Urethral diverticulectomy if indicated
- Laparoscopic sacral colpopexy for problematic retroverted uterus
- Laparoscopic lysis of adhesions if indicated
- Laparoscopic endometriosis excision or ablation
- Topical corticosteroids for vulvar hyperplasia or testicle for lichen sclerosis
- Topical estrogen for atrophy considering benefits and risks

Second Line
- Appropriate dose and duration of antibiotics or antifungals for infection
- Use of antibiotics or estrogen agonist/antagonist or fluconazole concomitantly
- Careful consideration of replacing condoms or other barrier devices with another contraceptive

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
- Daily passive dilatation with progressive vaginal dilators for stenosis
- Use of pressure for problematic retroverted uterus
- Pain/flat physiotherapy or biofeedback for muscle spasms
- Ultrasound or electrical stimulation for persistent muscle spasm
- Tibolone (synthetic, steroid) is commonly used in Europe in postmenopausal women with desire and arousal disorders

Complementary & Alternative Therapies
- Education, sex therapy, psychotherapy, and cognitive behavioral therapy are also important in the multidisciplinary management of sexual dysfunction including those with a history of sexual abuse.
- Currently there are limited studies on the effectiveness of herbal remedies to aid female sexual dysfunction in general.

ONGOING CARE

PROGNOSIS
- Results vary with etiology and treatment of many is long term
- Minimal risk to approach any etiology should be most beneficial

FOLLOW-UP

Patient Monitoring
- Frequent follow-up with initiation of new behavioral or medical therapies is best
- Upon resolution and improved patient satisfaction follow-up may be spaced out

CODES

ICD9
- 627.3 Postmenopausal atrophic vaginitis
- 627.9 Other atrophic vaginitis

ICD10
- F52.6 Dyspareunia not due to a substance or known physical condition
- N94.1 Dyspareunia
- N95.2 Postmenopausal atrophic vaginitis

CLINICAL/SURGICAL PEARLS
- Do not discount behavioral interventions.
- Topical estrogen can work wonders.
- Changing the hygienic routine can help.
DYSURIA
Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

DESCRIPTION
Dysuria is the symptom of discomfort, burning, or pain during urination.
It is often associated with other lower urinary tract symptoms.

EPIDEMIOLOGY
Incidence
Dysuria accounts for up to 15% of visits to family doctors.
In men the incidence increases with age and 5% of men seek medical help for dysuria.

Prevalence
In the United States the reported prevalence of dysuria is 25%.

RISK FACTORS
See associated conditions.

GENETICS
N/A

PATHOPHYSIOLOGY
• Dysuria results from the irritation of the urethra or bladder by inflammation or irritants.
• The transient receptor potential subfamily vanilloid type 1 receptor (TRPV1) exists in the urethra.
• Inflammatory mediators such as leukotrienes activate TRPV1 and result in pain and burning during voiding.

ASSOCIATED CONDITIONS
• Bladder or urethral cancer
• BPH
• Connective tissue diseases
• Behcet (reactive arthritis) syndrome
• STD
• Urethral stricture disease
• Urinary tract infection
• Urolithiasis

GENERAL PREVENTION
• Hydration to flush out the urinary tract
• Women should wipe from front to back after bowel movements.
• Women should empty the bladder immediately after intercourse.
• Keep the genital area clean and dry.
• Avoid irritating soap and vaginal products.
• Treat infection with antibiotics.

DIAGNOSIS

UNEXPLAINED DYSURIA MAY INDICATE CANCER IN SITU OF THE BLADDER.

HISTORY
• The cause of dysuria can be challenging to diagnose.
• Dysuria is frequently associated with other lower urinary tract symptoms such as urinary frequency, hesitancy, urgency, and nocturia (1).
• Age and sex (2):
  • Dysuria is more common in women.
  • The most common cause in young women is urethritis, in middle age women genitourinary causes, and in elderly women urinary tract infection.
• The most common cause in young men is urolithiasis and in elderly men benign prostatic hyperplasia (BPH) and urinary tract infection.
• Dysuria in children may suggest sexually transmitted diseases (STD).
• Onset:
  • Sudden onset symptoms suggest acute bacterial infection.
  • Gradual onset symptoms may suggest Chlamydia trachomatis infection.
• Timing of pain:
  • At the onset of voiding indicates inflammation such as urethritis.
  • At the middle of voiding indicates obstruction such as urethral stenosis or BPH.
  • At the end of voiding usually indicates bladder pathology such as cystitis.
• Location of pain:
  • External discomfort associated with vaginal infection or inflammation.
  • Internal discomfort indicates bladder or urethral origin.
• Associated symptoms:
  • Frequency, urgency, and suprapubic pain suggest diagnosis of interstitial cystitis.
  • Frequency, nocturia, and reduced flow suggest bladder outlet obstruction or urethral stricture.
  • Fever, rigor, and flank pain suggest pyelonephritis or urethritis.
• Urethral discharge in young age indicates sexually transmitted diseases.
• Vaginal irritation, discharge, and dyspareunia indicate genital tract infection such as:
  • Virovaginitis, atrophic vaginitis, or sexually transmitted diseases.
• Urethral discharge in young age indicates sexually transmitted diseases.
• Vaginal irritation, discharge, and dyspareunia indicate genital tract infection such as:
  • Virovaginitis, atrophic vaginitis, or sexually transmitted diseases.
• Dyspareunia + dribbling + dysuria (“3 Ds”) suggests a urethral diverticulum in females.
• The presence of joint or back pain may indicate connective tissue diseases.
• Significant urgency occurs as a result of irritation of the bladder trigone and posterior urethra due to inflammation, bladder stone, or tumor.
• Oral and genital ulcers, vesicles, ulcers with dysuria suggest Behcet disease.
• History of recent surgery such as urethral instrumentation or continent surgery and history of recent catheterization should be obtained to rule out infection, inflammation, and urethral erosion.
• Sexual history:
  • Sexual behavior
  • The use of contraceptives, diaphragms, condoms, etc.
• Previous history of sexually transmitted diseases and history of urethral straining.
• Drug history: Drugs associated with dysuria are morphine, perindopril, ciprofloxacin, saw palmetto, dopamine.

PHYSICAL EXAM
• General exam and observation should be recorded.
• Abdominal exam:
  • Inspection: Look for skin rash and abdominal distension which indicate full bladder.
  • Palpation: Feel for loin tenderness, palpable bladder, suprapubic tenderness, abdominal masses, and midline pulsation.
  • Percussion: To detect full bladder or any other abdominal masses.
• Association: To rule out other causes of abdominal distension.
• Male genital exam:
  • Look for any penile lesions, urethral discharge, muscular tendons, balanitis, perineal bruising, and abnormalities in the foreskin.
  • Examine the scrotum for swelling, tenderness, and testicular masses.
• Digital rectal exam to rule out prostatitis, benign prostatic enlargement, and prostate cancer.
• Female genital exam (3):
  • Look for vaginal and urethral discharge.
  • Vulval lesions such as ulcers, vesicles, and rash.
  • Identify urethral lumps that indicate urethral fenestration, diverticulum, or stones. Look for signs of atrophic vaginitis.
  • Pelvic exam: Adnexal and cervical tenderness which indicates pelvic inflammatory disease, uterine tenderness, and uterine masses.
  • Bimanual exam to look for pelvic masses.

DIAGNOSTIC TESTS & INTERPRETATION LAB
• Urine dipstick is a useful and easy test to screen for urinary tract infection.
• A positive test for nitrites is suggestive of urinary tract infection. A negative test does not rule out infection.
• A positive leukocyte esterase suggests the presence of white blood cells in the urine which is associated with inflammation. It has 75% sensitivity to detect infection.
• Urine microscopy:
  • Pyuria is defined by the presence of 3–5 white blood cells per high power field.
  • Hematuria is defined by the presence of 3–5 red blood cells per high power field.
• Sterile pyuria is present in urinalysis, transitional cell carcinoma, and atypical microorganisms such as tubercle.
DIFFERENTIAL DIAGNOSIS

Based on specific diagnosis

Pathologic Findings

DIFFERENTIAL DIAGNOSIS

- Disease of the urinary tract
  - Urinary tract infection
  - Urolithiasis, bladder calculus, crystalluria
  - Intestinal cystitis
  - Prostatitis (acute, chronic bacterial and chronic pelvic pain syndrome)
  - Gynecologic (cervical in situ, prostate cancer, urethral cancer)
- Disease of the genital tract
  - Sexually transmitted disease
  - Gonorrhea, Chlamydia, and herpes simplex infection
  - Vulvo-vaginitis, orchitis, pelvic inflammatory disease
- Epidermitis
- Urethral diverticulum
- Systems diseases
  - Connective tissue diseases: Reiter reactive arthritis syndrome and Behcet disease
  - Local irritants
    - Chemical irritants: Cystophosphamide, laundry detergents, bubble baths, intraurethral lubricants
    - Mechanical irritation: Radiation cystitis
  - Infections and adolescents
  - Laceration
  - Exploratory sexual activity, masturbation

Diagnosis

- Gram staining demonstrate the urinary pathogens
- Urine culture and sensitivity identify the causative microorganism of urinary tract infection and its antimicrobial susceptibilities
- Bacterial count of more than 1,000 colony forming units is diagnostic
- Vaginal and uterine smears: Important for the diagnosis of sexually transmitted diseases
- Vaginal pH measurement, potassium hydroxide

Diagnostic Procedures/Surgery

- Visual vaistoscopy: Allows careful assessment of the urethra
- Imaging
  - Renal ultrasound scan in suspected cases of upper tract pathology, urethral, and bladder abnormalities
  - Plain abdominal x-ray in suspected cases of urethralis and ephymematous peritonitis and pyoneum
- Other imaging modalities can be arranged according to the suspected diagnosis such as voiding cystourethrogram, retrograde urethrogram, computed tomogram with intravenous contrast, magnetic resonance imaging

Medication

- Erythromycin: Used as a primary treatment for gonorrhea
- Antibiotics according to the causative organism

Surgical management is reserved for specific causes

ADDITIONAL TREATMENT

Dysuria

- Treat the primary cause
- Personal hygiene
- Protection measures against STD
- Treat the primary cause

PROGNOSIS

- Unexplained persistent dysuria should NEVER be ignored; must rule out occult malignancy, such as carcinoma in situ of the bladder
- Persistent hematuria after adequate treatment of dysuria related to UTI must have formal hematuria workup.
EDEMA, EXTERNAL GENITALIA (LYMPHADEMA, PENO-SCROTAL EDEMA)
Megan M. Merrill, DO

ASSOCIATED CONDITIONS
- Advanced prostate cancer
- Anemia
- Acute/chronic failure
- Congestive heart failure
- Renal failure
- Symmetrical lymphedema (lymphangitis filariasis)
- Paraphimosis
- Renal insufficiency/renal failure
- Retroperitoneal lymphadenopathy
- Testicular torsion

DIAGNOSIS
- EDEMA: The penis and scrotum in an uncircumcised male may indicate paraphimosis, which requires immediate foreskin reduction to avoid glans penis vascular compromise (1).
- EDEMA of the scrotum with areas of necrosis or devitalized skin may indicate Fournier gangrene and requires emergent urologic consultation and surgical debridement.

PHYSICAL EXAM
- Palpate for an increase in subcutaneous tissue and may suggest etiology.
- Foul odor associated with Fournier gangrene
- Bruising or induration with crepitance seen in Fournier gangrene

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- No specific lab tests
- Elevated brain natriuretic peptide (BNP) associated with hypervolemia
- Fractional sodium excretion may suggest fluid overload

Imaging
- Scrotal ultrasound (US) confirms thickened subcutaneous tissue and may suggest etiology.
- CT may suggest retroperitoneal etiology.

Diagnostic Procedures/Surgery
- Physical exam significant for indicating edema of the genital skin
- Pathologic Findings
- Edematous subcutaneous tissue of the scrotum and perineal skin with possible areas of devitalized skin or necrosis

DESCRIPTION
- Pitting or nonpitting edema of the penis shaft and scrotal skin due to the accumulation of transudative fluid in the dartos (scrotal) or subcutaneous layer of the penis

EPIDEMIOLOGY
- Incidence
- Prevalence
- Risk Factors
- Genetic
- Prevalent condition in nursing home and hospitalized patients
- Incidence is not well documented

PATHOPHYSIOLOGY
- Accumulation of transudate within the subcutaneous tissue of the penis and scrotum
- May be localized to the genital region or part of generalized lower extremity edema or massive body edema (anasarca).
- In generalized edema capillary hemodynamics are altered and fluid moves from vascular space to interstitium according to Starling’s law (2).

BASICS
- Physical manifestation of macro-orchidism/scrotal edema that becomes more apparent in puberty (1).

ASSOCIATED CONDITIONS
- Advanced prostate cancer
- Anemia
- Acute/chronic failure
- Congestive heart failure
- Renal failure
- Symmetrical lymphedema (lymphangitis filariasis)
- Paraphimosis
- Renal insufficiency/renal failure
- Retroperitoneal lymphadenopathy
- Testicular torsion

DIAGNOSIS
- EDEMA: The penis and scrotum in an uncircumcised male may indicate paraphimosis, which requires immediate foreskin reduction to avoid glans penis vascular compromise (1).
- EDEMA of the scrotum with areas of necrosis or devitalized skin may indicate Fournier gangrene and requires emergent urologic consultation and surgical debridement.

PHYSICAL EXAM
- Palpate for an increase in subcutaneous tissue and may suggest etiology.
- Foul odor associated with Fournier gangrene
- Bruising or induration with crepitance seen in Fournier gangrene

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- No specific lab tests
- Elevated brain natriuretic peptide (BNP) associated with hypervolemia
- Fractional sodium excretion may suggest fluid overload

Imaging
- Scrotal ultrasound (US) confirms thickened subcutaneous tissue and may suggest etiology.
- CT may suggest retroperitoneal etiology.

Diagnostic Procedures/Surgery
- Physical exam significant for indicating edema of the genital skin
- Pathologic Findings
- Edematous subcutaneous tissue of the scrotum and perineal skin with possible areas of devitalized skin or necrosis
DIFFERENTIAL DIAGNOSIS
- Acute idiopathic scrotal edema
- Angiokeratoma of the genital skin
- Cellulitis
- Chemical or allergic dermatitis
- Elephantiasis
- Epidermolysis-architects
- Fourier gangrene
- Hydrocele
- Lymphoedema of scrotal edema (usually children)
- Inguinal hernia
- Paraphimosis
- Retropertioneal mass
- Squamous carcinoma of penis
- Testicular torsion
- Varicocele

ADDITIONAL TREATMENT
Radiation Therapy
While this can be a cause of genital lymphedema, it may have a role in primary palliative treatment of prostate, penis, and retroperitoneal malignancies causing scrotal edema.

Additional Therapies
Supportive undergarments/briefs for patient comfort

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
Depends on etiology

COMPLICATIONS
- Skin breakdown/ulceration
- Urinary retention/obstructive voiding
- Genital and scrotal compression is NOT recommended

FOLLOW-UP
Patient Monitoring
- Physical exam for resolution
- Monitor underlying condition, appropriate labs, nutritional status

Patient Resources

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Edema, Lower Extremity, Urologic Considerations
- Fourier Gangrene
- Testicular Torsion
- Paraphimosis
- Edema, External Genitalia (Lymphedema, Peno-Scrotal Edema) Image

CODES
ICD9
- 605 Redundant prepuce and phimosis
- 607.83 Edema of penis
- 608.86 Edema of male genital organs

ICD10
- N47.1 Phimosis
- N48.89 Other specified disorders of penis
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS
- Determine the patient’s fluid status to rule out hypervolemia as the cause of genital edema.
- Acute scrotal pain, swelling, lack of cremasteric reflex, and a high-riding ipsilateral testis could indicate testicular torsion.
- Evaluate for paraphimosis in uncircumcised males.
- Crepitance, induration, necrosis, and foul odor suggest Fournier gangrene and require emergent surgical debridement.
- Complications of edema may include urinary retention and skin breakdown—these should be evaluated for and treated accordingly.
EJACULATION, PREMATURE (PREMATURE EJACULATION)

Elizabeth K. Peacock, MD
James S. Rosoff, MD

**BASICS**

**DESCRIPTION**

- Definition of premature ejaculation (PE) remains controversial:
  - ISSM (2008): Ejaculation within about a minute and inability to delay ejaculation with all or nearly all vaginal penetrations causing negative personal consequences (1)
  - WHO (2004): Inability to delay ejaculation with intercourse before/soon after starting intercourse (15 s)
  - AUA (2004): Ejaculation sooner than desired, before or shortly after penetration that causes distress to 1/both partners
  - EAU (2001): Inability to control ejaculation for sufficient time before vaginal penetration
  - APA (2001): Persistent or recurrent ejaculation with minimal sexual stimulation

- May also be classified as primary (lifelong PE) or secondary (acquired PE)

- ICD-10 uses 15 s of intravaginal ejaculatory latency time (IELT) as a cutoff

**EPIDEMIOLOGY**

- Incidence: Unknown
- Prevalence: PE is the most common sexual dysfunction in men <40
  - Approximately 20–30% in this group

**RISK FACTORS**

- Increased levels of arousal due to new partner or situation
- Low frequency of sexual activity
- Genetics
  - Polymorphism in the serotonin transporter promoter region (5-HTTLPR) may play a genetic role in the etiology and/or treatment of PE, though this is controversial.

**PATHOPHYSIOLOGY**

- Serotonin receptor stimulation (5-hydroxytryptamine):
  - Serotonin 5-HT 2c receptors inhibit ejaculation, 5-HT 1a receptors facilitate ejaculation
  - Hyposensitivity of 5-HT 2c or hypersensitivity of 5-HT 1a may cause PE
  - Increase in serotonin transporter (5-HTT) may play a genetic role in PE
- Consider psychological factors, hormone alterations, penile sensitivity, circumcision status, chronic prostatitis as potential causes though with limited evidence supporting these

**ASSOCIATED CONDITIONS**

- Erectile dysfunction
- General anxiety
- Situational anxiety
- Depression
- Substance abuse
- Relationship distress
- Prostatitis

**GENERAL PREVENTION**

**DIAGNOSIS**

**HISTORY**

- Time to ejaculation is essential
- Duration/frequency of PE
- Rate of occurrence of PE
- Degree of sexual stimulation causing PE
- Nature/frequency of sexual activity including foreplay, masturbation, and intercourse
- Discuss length of time experiencing PE, perceived lack of control, and resultant sexual dissatisfaction
- Any indication of ED
- Issues with the partner, such as dyspareunia or other medical problems
- Rule out symptoms consistent with cystitis or prostatitis
- Medication history: Consider PE due to withdrawal from narcotics or trifluoperazine (Stelazine)
- Sexual History
  - Global to all sexual encounters, or with specific situations and/or partners
  - Religious upbringing
  - Early sexual experiences
  - Sexual relationships, past and present
  - Religious upbringing
  - Early sexual experiences
  - Sexual relationships, past and present
  - Conflicts or concerns within current relationship
  - Traumatic sexual experiences

**PHYSICAL EXAM**

- Complete physical exam with focus to rule out biologic causes including recent pelvic surgery or infectious source
- Recall exam to assess for prostatitis
- Rare to have findings on exam that would define etiology or change management

**TREATMENT**

**GENERAL MEASURES**

- Behavioral treatment:
  - Stop–squeeze method (Masters and Johnson) involves removal of penis at point of ejaculation with squeezing of glans or frenulum
  - Start–stop method (Seman) involves a pause in intercourse at point of ejaculation
  - High initial success rates are reported, but poor long-term rates are present due to the time-consuming nature of treatment
- Psychotherapy may be beneficial
- Combination of pharmacotherapy and psychotherapy is suggested as current model for treatment

**DIAGNOSTIC TESTS & INTERPRETATION**

- Lab: Usually unnecessary
- Imaging: N/A
- Pathologic Findings: N/A
- Diagnostic Procedures/Surgery: N/A
- Pathologic Findings: N/A
EJACULATION, PREMATURE (PREMATURE EJACULATION)

MEDICATION

First Line

- No medications are approved for treatment of PE in the United States
  - SSRIs:
    - Elevates level of serotonin in synapse that results in prolongation of ejaculatory latency time
    - 1st-line pharmacotherapeutic approach (off-label)
    - Daily treatment with PO paroxetine 20–40 mg (greatest evidence), sertraline 25–200 mg, fluoxetine 5–20 mg
    - Newer agents have not been effective (fluvoxamine/venlafaxine)
    - Dapoxetine approved in Europe only for on-demand dosing for PE

- Topical agents:
  - EMLA: Lidocaine–prilocaine 2.5% cream
  - TEMPE: Metered-dose aerosol spray with lidocaine 7.5 mg and prilocaine 2.5 mg per spray

Second Line

- Clomipramine:
  - Tricyclic antidepressant
  - Daily treatment with 25–50 mg or on-demand treatment with 50 mg 5 hrs prior to intercourse

- Tramadol (synthetic opioid analgesic) with potential treatment role in PE (little evidence) (2)

SURGERY/OTHER PROCEDURES

CT-guided cryoablation of unilateral dorsal penile nerve (single study, 24 patients) (3)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

European Medicines Agency’s Committee for Medicinal Products for Human Use (CHMP) has recommended authorization of a cutaneous spray containing a mixture of 150 mg lidocaine and 50 mg prilocaine per milliliter applied to the glans

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Varies by treatment modality. May have up to 80% success rate with medication and/or behavioral modification

COMPLICATIONS

- Medications carry side effects, but complications of PE are limited
- Rarely, a problem with fertility may exist due to inability to complete intercourse
- May provoke anxiety or depression if PE is severe
- May interfere with development of sexual relationship

FOLLOW-UP

Patient Monitoring

N/A

- Dysorgasmia (Painful Orgasm), Male
- Ejaculatory Disturbances (Delayed, Decreased, or Absent)
- Ejaculation Premature Algorithm

CODES

ICD9

302.75 Premature ejaculation

ICD10

P52.4 Premature ejaculation

CLINICAL/SURGICAL PEARLS

- Exact definition of PE remains controversial.
- Combination of pharmacotherapy (off-label use) and psychotherapy is likely the most beneficial treatment.
EJACULATORY DISTURBANCES (DELAYED, DECREASED, ABSENT)

Pravin K. Rao, MD

BASICS

DESCRIPTION
- Anorgasmia or delayed orgasm/ejaculation
- Difficulty/habitual to reach orgasm
- Low-volume ejaculates
- Testosterone analysis
- Aspermia
- Orgasm with zero ejaculate volume
- Retrograde ejaculation
- Sperm seen in post-ejaculatory urine
- Ejaculatory duct obstruction (EDO)
- Congenital, acquired, iatrogenic
- Failure of emissions
- Can also cause low/zero volume

EPIDEMIOLOGY

Incidence
- Increased in aging (age 50–80 yr) men with
  BPH/LUTS (11B)
  ~46% decreased ejaculation
- ~15–30% anejaculation
  ~90% report decreased ejaculatory volume
- Selective serotonin reuptake inhibitors (SSRIs)
  ~16–37% delayed or difficult orgasm
- Anorgasmia is rare:
  ~0.14–0.4% in general population
- Prevalence

RISK FACTORS

- Age
- Benign prostatic hyperplasia
- Lower urinary tract symptoms
- Prostatitis/Ejaculatory duct stones
- Depression and related medications
- Hypogonadism
- Hypertension medications
- Prostate/retroperitoneal/Bladder neck surgery
- Retropertoneal lymph node dissection (RPLND)
- Cystic fibrosis
- Neurologic conditions/Diabetes
  - Multiple sclerosis, spinal cord injury (SCI), spina bifida, diabetes
- Rectal surgery
- Radiation therapy

Genetics
- N/A

PATHOPHYSIOLOGY

- Normal ejaculation:
  - Central control in multiple brain regions
  - Can promote or inhibit ejaculation
  - Sympathetic (T12-L3):
    - Sympathetic (T12–L3):
      - Hypogastric nerve (thoracolumbar)
      - Seminal emission by contraction of epididymis, vas deferens/ampulla, seminal vesicle (SV), and prostate smooth muscle
  - Bladder neck closure preventing retrograde ejaculation
  - Parasympathetic (S2–S4):
    - Pelvic nerve
    - Gland secretions of prostate SV
      - Prostatectomy or removal of prostate bump
      - Sensory
    - Prostatic nerve
    - Efferents from sacral cord
      - Relaxation of external urethral sphincter
      - Pelvic nerve
      - Prostate smooth muscle
      - Ejaculation requiring intact, properly developed, and coordinated accessory sex organs
      - Ejaculation requires intact, properly developed, and coordinated accessory sex organs, nerves, and muscles
      - Congenital, acquired, iatrogenic, infectious, inflammatory causes can all prevent normal ejaculation
      - Functional causes may lead to the complaint of decreased force of ejaculation
      - Ejaculate volume commonly decreases by ~0.03 mL each year with advanced age

ASSOCIATED CONDITIONS

- Psychological/Psychiatric conditions
  - See Risk Factors

GENERAL PREVENTION

- Avoidance of bladder neck procedures
  - Transurethral prostate, bladder neck surgery
- Avoidance/reduced use of medications
  - SSRI, v-blockers, 5a-reductase inhibitors
- Nerve sparing at time of RPLND
- Strict diabetic control

DIAGNOSIS

HISTORY

- Duration of symptoms
  - No defined criteria for diagnosis of delayed ejaculation
  - Mostly normal men ejaculate after 4–10 min of penetration
  - Presence of significant distress to patient or partner important to diagnosis
  - Presence or absence of orgasm
  - Perceived ejaculate volume
  - Sources of stress/psychological disturbance
  - Past medical history
  - Retroperitoneal and genitourinary operations
  - Family history of erectile dysfunction
  - See vas deferens, congenital absence
  - Medications:
    - Antidepressants/antipsychotics
    - Bladder outlet medications
  - Anorgasmia/Delayed orgasm

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Semen analysis
  - Volume: Suspect if ejaculate volume <1.5 cc
  - Concentration: Low volume azoospermia suspicious for EDO
  - Absence of seminal fructose suggests EDO
  - Post-ejaculatory urine analysis (PEU): >10–15 sperm/HPF demonstrates retrograde ejaculation

Imaging

- Transrectal ultrasound (TRUS)
  - Visualization for low volume azoospermia
  - For patients with negative PEU
  - Normal SV A-P diameter <1.5 cm
  - MRI
  - Can help identify structural abnormalities

PHYSICAL EXAM

- Absence or diminished development of epididymides and vas deferens
  - Congenital bilateral or unilateral absence of the vas deferens (CBVD/CUAVD)
  - Enlarged SV
  - EDO
  - Hypospadias or epispadias
  - Hypogonadism

DIAGNOSTIC TESTS & INTERPRETATION
EJACULATORY DISTURBANCES (DELAYED, DECREASED, ABSENT)

Diagnostic Procedures/Surgery
- TRUS with TV aspiration: Presence of numerous sperm suggests obstruction
- Cystoscopy
- Retrograde ejaculation
- Vas Deferens, Congenital Absence
- Retrograde Ejaculation
- Varicoceles

Pathologic Findings
Scar tissue at ejaculatory duct

DIFFERENTIAL DIAGNOSIS
- Anorgasmia
- Retarded/Delayed orgasm
- Erectile dysfunction
- Pathologic Findings
  - May present as inability to reach orgasm, or with weak force of ejaculation
  - Retrograde ejaculation
  - Aspermia

MEDICATION
- EDO (ejaculatory duct obstruction)

GENERAL MEASURES
- Remove/modify correctible causes
  - Psychological/Stress factors
  - See images of PVS devices:
    - Procedure: Apply to ventral/frenular region for 1–3 min at a time, with 1 min rest periods, for up to 15–20 min
    - See images of PVS devices:
      - Fentices
      - Vibrates (dorsal and ventral stimulation)
      - Electroejaculation (EEJ) via rectal probe

- Autonomic dysreflexia
- Risk for SCI lesions above T6
  - Can occur with PVS or EEJ
- Consider nifedipine 10–20 mg PO 10–15 min before treatment initiated
  - Monitor at risk patients for hypertension, tachycardia, sweats
  - Retrieval of sperm from bladder
    - See “Retrograde Ejaculation”
  - Testicular or epididymal sperm retrieval
    - Requires IVF/ICSI
  - Donor sperm or adoption may circumvent the need to (IVF/ICSI)

TREATMENT

GENERAL MEASURES
- Treat erectile dysfunction
  - Psychological assessment/counseling
  - Treat erectile dysfunction
  - Sexual counseling on techniques for optimal arousal

MEDICATION

First Line
- Alphaline 21% vs. tamsulosin 90% of patients
- Psychological/Stress factors
- Psychological assessment/counseling
- Treat erectile dysfunction
- Sexual counseling on techniques for optimal arousal

SECOND LINE

RADIOGRAPHIC THERAPY
- Radiation Therapy

ADDITIONAL TREATMENT

RADIOGRAPHIC THERAPY
- Radiation Therapy

Additional Therapies
- Penile/flex physical therapy for associated symptoms of pain or voiding symptoms
- Cognitive-behavioral sex therapy
- Changing idiosyncratic masturbation style if present

COMPLEMENTARY & ALTERNATIVE THERAPIES

ONGOING CARE

PROGNOSIS
- Depends on the etiology, duration, and severity
- >40% SCI men doing PVS with home insemination of their partners can achieve pregnancy (33B)

COMPLICATIONS
- Infertility implications
- Relationship stress and difficulty

FOLLOW-UP

Patient Monitoring
Based on response to therapy and needs of specific patient

Patient Resources
N/A

- 608.89 Other specified disorders of male genital organs

ICD10
- F52.3 Male organic disorder
- N53.14 Retrograde ejaculation
- N53.19 Other ejaculatory dysfunction

Inclusion of partner in treatment important if recommending change in sexual practice.
ENURESIS, ADULT
Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

BASICS

DESCRIPTION
- Enuresis is repeated inability to control urine
  - Primary: Starts in childhood and never resolves and continues into adulthood
  - Secondary: New onset in adulthood
- Nocturnal enuresis (NE) is involuntary urination while asleep after the age at which bladder control usually occurs

ASSOCIATED CONDITIONS
- Pathophysiology
  - Genetics
    - 2.3% of adult population affected
  - Risk Factors
    - Family history of NE
    - If both parents have NE, children have 80% chance
  - Epidemiology
    - Enuresis is repeated inability to control urine
    - Nocturnal enuresis (NE) is involuntary urination while asleep after the age at which bladder control usually occurs

RISK FACTORS
- 35% of a 24-hr urine volume
- Urine production increased in recumbent position
- Disturbance in sensation, cortical arousal, or urinary sphincter function
- Decreased bladder capacity initiating involuntary voiding reflex
- Nocturnal polyuria because vasopressin secretion or reduction in renal sensitivity to the antidiuretic hormone (ADH)
- Detrusor instability during filling phase
- Bladder diaries/frequency-volume charts

PATHOPHYSIOLOGY
- Unknown in most situations
- Recognized hypotheses
  - Obstructive sleep apnea causing diminished vasopressin secretion
  - Decreased bladder capacity initiating involuntary voiding reflex
- Nocturnal polyuria
  - Due to decreased nocturnal excretion of urine
  - Caused by conditions affecting the kidneys
  - Associated with conditions affecting the heart
- Normal physiology decreases nighttime, relative to daytime, urinary output. Excess production of urine at night, in the setting of a normal 24-hr urine output, is termed nocturnal polyuria
- Nocturnal polyuria is the baseline of 24-hr urine volume

ASSOCIATED CONDITIONS
- Benign prostatic hypertrophy
- Daytime urinary incontinence
- Psychopathological disorders including depression
- Sleep apnea

GENERAL PREVENTION
- Timed voiding
- Complete bladder emptying
- Avoidance of caffeine and alcohol
- Adjust timing of fluid intake

DIAGNOSIS

HISTORY
- Have never achieved nocturnal continence of urine
- Non-specific urinary symptoms
- Ask about known or potential medical history
- Complete surgical and trauma incident history
- Obtain record of fluid intake habits
- Review medications and times of administration
- Voiding diaries to evaluate frequency, volume, and patterns
- International prostate symptom score (IPSS) in men

PHYSICAL EXAM
- Full urologic exam (pelvic exam in women and DRE in men)
- Full neurologic exam

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Urinalysis and urine culture: Rule out urinary tract infection, hematuria, proteinuria, glycosuria
  - Creatinine: Rule out renal insufficiency
- Urine cytology (if other symptoms such as irritative voiding symptoms make carcinoma a concern)
- Imaging
  - Post void residual bladder scan
  - Imaging: Imaging for possible abnormalities such as ectopic ureters
- CT urography
- Renal ultrasound

Diagnostic Procedures/Surgery
- Bladder diaries/frequency-volume charts
- Cystoscopy with retrograde pyelograms to evaluate bladder and ureters
- Urine cytology
- Vescouretal testing (VET)
- Bladder diaries/frequency-volume charts
- Cystoscopy with retrograde pyelograms to evaluate bladder and ureters
- Urodynamic testing (VET)
- Urodynamic testing: Test for abnormalities such as ectopic ureters
- CT urography
- Renal ultrasound
- Urodynamic testing: Test for abnormalities such as ectopic ureters
- CT urography

Pathologic Findings
- N/A

DIFFERENTIAL DIAGNOSIS
- Prostatic hypertrophy
- Neurogenic bladder
- Idiopathic detrusor instability
- Neurologic disorders

TREATMENT

GENERAL MEASURES
- Conservative measures have varying success rates
- Education is key when attempting to improve enuresis without medical therapy
- Timed voiding
  - Complete bladder emptying
  - If associated with BPH in men management with α-blockers for 5α-reductase inhibitors
- Avoidance of caffeine and alcohol
- Adjust timing of fluid intake
- Restrict fluid intake in evening to reduce urine output at night
- Take diuretics medications early in a day

MEDICATION

First Line
- If due to prostatic hypertrophy: See Section I
- "Bladder Outlet Obstruction (BOO)."
- Antimuscarinics or α3-agonists (α3)
  - Inhibit the effect of acetylcholine at postsynaptic muscarinic receptors on detrusor muscle cells
  - α3-Adrenergic agonist promotes detrusor muscle relaxation
  - Varying results (5–40%), depends on whether detrusor instability is not cause of enuresis
  - Side effects: Dry mouth, constipation, blurred vision, confusion

Antimuscarinics
- Ttolterodine (2–4 mg)
- Trospium XR (60 mg)
- Oxybutynin (5–15 mg)
- Solifenacin (5–10 mg)
- Oxybutynin ER (7.5–20 mg), XL 5–30 mg; patch twice-weekly
- Tolterodine (4–8 mg)
- α3-adrenergic agonist
  - Mirabegron (25–50 mg)

3-Adrenergic agonist

Mirabegron (25–50 mg)

Trospium XR (60 mg)

Oxybutynin (5–15 mg)

Solifenacin (5–10 mg)

Oxybutynin ER (7.5–20 mg), XL 5–30 mg; patch twice-weekly

Tolterodine (4–8 mg)

α3-adrenergic agonist

Mirabegron (25–50 mg)
Second Line

- **DDAVP (Desmopressin)** (5)
  - Not currently FDA approved for this clinical indication (has European regulatory approval)
  - Analog of vasopressin
  - Decreases urine production for about 5 hr
  - Decreases number of enuresis events but may not eliminate it completely
    - Oral 0.2 mg at bedtime, increase to 0.6 mg to response
    - Intranasal formulations are no longer indicated for the treatment of primary NE due to risk for severe hyponatremia with seizures and death
  - Side effects: Nasal irritation, dry mouth, sleep disruption, water intoxication, seizures, heart failure, electrolyte disturbances, hyponatremic coma
  - Use with extreme caution if at all in geriatric patients (>65 yr) due to risk of severe hyponatremia and other adverse events

- **Imipramine** (5)
  - Tricyclic antidepressant
  - Mild anticholinergic effect and α-action to increase internal sphincter tone
  - Side effects: Sleep abnormalities, decrease appetite, personality disturbances

SURGERY/OTHER PROCEDURES

- Consideration after all conservative and pharmacologic measures have failed
- If urodynamic testing shows detrusor overactivity, may consider additional interventions
  - Botulinum toxin injections
  - Sacral neuromodulation
  - Posterior tibial neuromodulation
  - Augmentation cystoplasty
  - Urinary diversion

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies

- Psychological counseling
- Assist with coping mechanisms and finding any potential underlying issues

Complementary & Alternative Therapies

- Enuresis (bedwetting) alarms
- Timed voiding through the day and night
- Decrease fluid hydration prior to bed
- Empty bladder to completion prior to bed

ONGOING CARE

PROGNOSIS

- Many patients may eventually become dry
  - This is more likely in children

COMPPLICATIONS

- Urea dermatitis
- Skin breakdown and superficial ulcers from direct contact of urine on skin
- Psychological effects
  - Job changes/decreased work performance
  - Depression
  - Low self-esteem
  - Decreased social activities

FOLLOW-UP

Patient Monitoring

- Long-term follow-up until resolution or satisfaction by the patient
- Psychological counseling and follow-up if necessary

Patient Resources

- The Simon Foundation for Continence (simonfoundation.org)
- National Association for Continence (www.nafc.org)

REFERENCES

ADDITIONAL READING

- http://www.nafc.org/Bladder-Bowel/Bedwetting/Adult-Bedwetting/

See Also (Topic, Algorithm, Media)

- Bladder Outlet Obstruction (BOO)
- Enuresis Algorithm
- Enuresis, Pediatrics
- Incontinence, Adult Male
- Nocturia
- Urge Incontinence
- Urgency, Urinary (Frequency and Urgency)

CODES

**ICD9**

- 307.6 Enuresis
- 788.30 Urinary incontinence, unspecified
- 788.36 Nocturnal enuresis

**ICD10**

- F98.0 Enuresis not due to a substance or known physiol condition
- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

- Evaluating for underlying conditions is important in new onset enuresis.
- Social implications are common.
- Enuresis raised the risk for nighttime falls in elderly.
BASICS
DESCRIPTION
• Primary (idiopathic) or secondary (neurogenic) – Incontinence due to pooling of urine in the vagina
• Nocturnal polyuria

ASSOCIATED CONDITIONS
• Neuropsychiatric disorders (children with attention deficit hyperactivity disorder 2.7 x more likely to have NE)
• Upper urinary obstruction and nocturnal sleep apnea. Apnea episodes result in increased secretion of atrial natriuretic factor
• Constipation
• Urinary tract infection

GENERAL PREVENTION
MNE may not be preventable but parents should maintain regular voiding and bowel patterns—may help reduce risk of developing MNE with UTIs.

DIAGNOSIC TESTS & INTERPRETATION
Diagnostic Procedures/Surgery
- Cystoscopy: Routine use should be avoided
- Urodynamics: Helpful in evaluating bladder or posterior urethral dysfunctions
- Uroflowmetry: Assesses bladder outlet obstruction
- VCUG when diagnosis suggests posterior urethral valves or in older males; also used to evaluate for bladder structure (unusual)
- Abdominal u-vue to evaluate for vesical abnormalities
- Abdominal ultrasound may be helpful in the assessment of select patients with potential anatomic causes

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Macroscopic urinalysis (dipstick) to determine glucosuria, proteinuria, UT. If glucosuria present, serum glucose at that time
- Urine文化学：May be considered in male patients, especially those who have failed initial therapy to ensure no anatomic problem
- SMH of the spine for children suspected of having a neurogenic bladder as etiology, for those patients who are compliant and fail all therapeutic alternatives for NMNE, or who have a neurocutaneous signature or other physical findings on the lower spine or physical exam

PATHOPHYSIOLOGY
• Complex, involving central nervous system, circadian rhythm (sleep and diuresis), and bladder function abnormalities

PHYSICAL EXAM
- Abdominal exam for distended bowel/bladder
- Lower limb inspection for stigmata of occult spinal dysraphism/behelvel cord (sacral dimple, hair tuft, hemangioma, lipoma or other neurocutaneous signatures, absence of a palpable sacrum, or excess fat overlying the sacral region suggestive of a lumbosacral abnormality)
- Genital exam for congenital anomalies such as ectopic ureter or a urogenital sinus (with or without a palpable sacral dimple or excess fat overlying the sacral region)
- Labial adhesions in girls
- Urethral abnormalities or phimosis in boys
- Gait abnormalities, high arched foot

DIFFERENTIAL DIAGNOSIS
• Ectopic ureter
• Posterior urethral valves
• Urinary structure

PATHOLOGIC FINDINGS
• Neurogenic bladder
• Ectopic ureter
• Posterior urethral valves
• Urinary structure

DIAGNOSTIC PROCEDURES/SURGERY
- Ultrasound: Aids in evaluating bladder compliance and function in children with known dysfunctional voiding or enuresis due to neurogenic bladder or posterior urethral valves
- Cystoscopy: Routine use should be avoided
- May be helpful in the assessment of select patients with potential anatomic causes

ASSOCIATED CONDITIONS
• Neuropsychiatric disorders (children with attention deficit hyperactivity disorder 2.7 x more likely to have NE)
• Upper urinary obstruction and nocturnal sleep apnea. Apnea episodes result in increased secretion of atrial natriuretic factor
• Constipation
• Urinary tract infection

- May be helpful in the assessment of select patients with potential anatomic causes
TREATMENT

GENERAL MEASURES (2–4)
- Before embarking on any therapy, the interest and ability of the child and family to comply should be determined.
- Patience and compliance should be emphasized, because many months may be required to achieve improvement or resolution.
- Motivational therapy should be encouraged in almost every case; it is useful in conjunction with other treatments.
- Behavioral therapy is prerequisite to medications in most patients with nonspontaneous NE.
- Enuresis alarm for MNE works with well motivated families and children.
  - Treatment may take 2–3 mo.
  - Mechanism of action for behavioral therapy unclear.
  - Initial cure rate as high as 75%, suggest 4 mo of conservative dryness.
  - Relapse can be high, but 50% achieve long-term care.

MEDICATION

First Line
- DDAVP (desmopressin) for NE:
  - 0.2–0.6 mg PO 1 hr before bed. No fluid intake 2 hr before and 8 hr after bedtime.
  - Success rate 70–80%.
- Caution in patients with cystic fibrosis (hyponatremic dehydration)
- Tapering schedule imperative.
- Give parents copy of FDA warning (Dec 2007).
- Tapering schedule imperative.
- Caution in patients with cystic fibrosis.
- ∼2 hr before and 8 hr after bedtime.
- Give parents copy of FDA warning (Dec 2007).
- Tapering schedule imperative.
- Caution in patients with cystic fibrosis.
- ∼2 hr before and 8 hr after bedtime.
- Give parents copy of FDA warning (Dec 2007).
- Tapering schedule imperative.
- Caution in patients with cystic fibrosis.

Second Line
- Imipramine for NE:
  - Tricyclic antidepressant with prolonged QT interval.
  - Imipramine overdose can result in seizure.
  - Tapering dose 25–50 mg.
  - Success rates of 25–40%, but relapse rates can be high.
  - ∼2 hr before and 8 hr after bedtime.
  - Give parents copy of FDA warning (Dec 2007).
  - Tapering schedule imperative.
  - Caution in patients with cystic fibrosis.

THERAPIES

- Behavioral therapy is effective in cases of dysfunctional voiding. Most helpful in addition to improved voiding and bowel habits.
- Child must have sufficient cognitive ability to understand teaching.

ONGOING CARE

PROGNOSIS
- After age 6: spontaneous resolution rate of 15%/yr for bedwetters.
- After age 15, <1% have NE.
- Over 6.5 yr of follow-up:
  - 84% no longer wet at night.
  - 20–50% dry during the day.
  - Persistence of enuresis into adulthood (2–3%)
- After age 5, spontaneous resolution rate of 15%/yr.
- After age 15, spontaneous resolution rate of 15%/yr.
- After age 5, spontaneous resolution rate of 15%/yr.

FOLLOW-UP

Patient Monitoring
- Children with history of UTI or organic causes of enuresis should be followed for the specific condition.
- Monitor closely while on medication to treat the primary condition.

Patient Resources
- International Children’s Continence Society.
  - http://iccs.org/pamphlets/

SURGERY/OTHER PROCEDURES
- Only in cases of congenital anomalies (ectopic ureter, posterior urethral valves, etc.)
- Neurosurgical intervention for spinal anomalies, tethered cord.

ADDITIONAL TREATMENT

Radiation Therapy

- Additional Therapies
  - Children with dysfunctional voiding/elimination syndromes may benefit from elimination training program and selective use of anticholinergic medications.
  - Bacteriuria with LUTS and voiding dysfunction.

CODES

ICD9
- 596.6 Enuresis
  - 788.30 Urinary incontinence, unspecified
  - 788.36 Nocturnal enuresis

ICD10
- N38.4 Nocturnal enuresis
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

The primary therapy for all children with NE should be initial behavioral management before relying on medications.
EPIDIDYMIS, MASS (EPIDIDYMAL TUMORS AND CYSTS)
Ramiro J. Madden-Fuentes, MD
Judd W. Moul, MD, FACS

PHYSICAL EXAM
• Sandal exam—Identify location of mass—single or multiple
  • Compare with contralateral scrotal contents
  • Evaluate if fluid, mobile, indurated, or encroaching on other structures
  • Identify spermatic cord defects
  • Scars from vasectomy—sperm granuloma, epididymal inclusion cyst
  • Bowel mass for associated masses
• Intrapelvic exam—Evaluate for lymphadenopathy
• Hema

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Urinalysis: To evaluate for UTI. Include urine culture if suspicious for infection
  • Tumor markers if any concern for testicular mass
• Serum α-fetoprotein (AFP), β-human chorionic gonadotropin (β-hCG), lactate dehydrogenase (LDH)
• Purified protein derivative (PPD) if TB suspected

Imaging
• Sonar ultrasound—Solid vs. cystic
  • Location—testicular or paratesticular
  • Vascular or avascular
  • Cannot reliably differentiate between malignant or benign
  • Chest x-ray if TB suspected
• If mbenign tumor and >10 yr old—CT scan of the abdomen and pelvis with contrast to evaluate for retroperitoneal nodes (23A)

Diagnostic Procedures/Surgery
• Raney needle for epididymal lesions
• Painful approach
• Frozen section for pathology, proceed to orchiectomy with high cord ligation if malignant

Pathologic Findings
• Benign
  • Adenomatoid—Epididymal cystadenoma/papillary cystadenoma
  • Spermatocele
• Malignant
  • Rhabdomyosarcoma
  • Leiomyosarcoma
  • Fibrosarcoma
  • Metastatic carcinoma

DIFFERENTIAL DIAGNOSIS
• Adenomatous tumor of the epididymis:
  • Most common solid tumor of the epididymis
• Ectopic tissue:
  • Adrenal cortical rests
  • Sphenogonadal fusion
• Epididymal cyst

• Epididymal cystadenoma/papillary cystadenoma:
  • 2/3 associated with von Hippel–Lindau syndrome
  • 1/3 of all epididymal tumors
• Testicular tumors:
  • Acute, very tender on exam
  • Chronic; may have secondary calcification
  • Common cause of epididymal pain
• Renal cysts
• Fibrous pseudotumor
• Reticulosis
• Granulomas: Sarcoidosis, TB, histoplasmosis
• Varicocele
• Hydrocele of the cord
• Leiomysarcoma
• Malignant epididymal tumor:
  • Primary (very rare): Liposarcoma, rhabdomyosarcoma (high on differential in children), leiomyosarcoma, adenocarcinoma, lymphoma
  • Metastatic: Prostate, kidney, stomach most common
• Repillary cystadenoma
• Polyorchidism
• Sperm granuloma:
  • Sarcoid
  • Spem granuloma:
  • Seen in 40% postvasectomy or 2.5% idiopathic in general population
  • Granulomatous lesion with few giant cells
  • Consequence of extravasation of spermatozoa generally postvasectomy (al vascocenized men and general population)
• Testicular tumors:
  • TB of the epididymis
• Vasitis
• Vasa and vasiis nodosa (usually associated with epididymitis)
• Young syndrome (obstructive azoospermia, sinusitis, bronchiectasis)
Therapies
Complementary & Alternative

Use of radiation for local control of
Radiation Therapy
ADDITIONAL TREATMENT

SURGERY/OTHER PROCEDURES
- Excision of suspicious lesion via inguinal approach
- Frozen section
- If positive for malignancy, radical orchiectomy
- Doxycycline 100 mg PO BID
- Levofoxacin 500 mg PO daily x 10 days

EPIDIDYMIS, MASS (EPIDIDYMAL TUMORS AND CYSTS)

Ongoing care
Prognosis
- Adenomatoid tumors
- Benign, excellent prognosis
- Rhabdomyosarcoma
- In children with low stage disease survival may be as high as 90%; Worst stage (IV), survival is ~5.2% (4A)

Complications
- Uninfected epididymitis can cause severe systemic illness
- More advanced infections can present with testicular swelling and pain (epididymo-orchitis)
- If radiation or chemotherapy needed:
- Vincristine, cyclophosphamide, dactinomycin

Ongoing care
Prognosis
- Adenomatoid tumors
- Benign, excellent prognosis
- Rhabdomyosarcoma
- In children with low stage disease survival may be as high as 90%; Worst stage (IV), survival is ~5.2% (4A)

Complications
- Uninfected epididymitis can cause severe systemic illness
- More advanced infections can present with testicular swelling and pain (epididymo-orchitis)
- If radiation or chemotherapy needed:
- Vincristine, cyclophosphamide, dactinomycin

Follow-up
Patient Monitoring
- Oncologic follow-up if malignant disease
- Teach patient testicular self-exam

Additional treatments
Radiation Therapy
Use of radiation for local control of rhabdomyosarcoma in young patient is controversial

Additional Therapies
- Chemotherapy
- Vincristine, cyclophosphamide, dactinomycin may have a role in rhabdomyosarcoma depending on extent of disease and oncologist recommendations (4A)

Complementary & Alternative Therapies

Other
- Epididymitis (3[A]
- TB: Treat according to current CDC guidelines
- In young men and treat accordingly (See “Sexually Transmitted Diseases Treatment Guidelines”, General)
- Older men more likely to be infected by enteric organisms (Escherichia coli)
- As most epididymal lesions are benign, observation may be as high as 90%; Worst stage (IV), survival is ~5.2% (4A)
- If positive for malignancy, radical orchiectomy
- Frozen section
- Excision of suspicious lesion via inguinal approach
- Doxycycline 100 mg PO BID x 10 days
- Levofoxacin 500 mg PO daily x 10 days
- - Vincristine, cyclophosphamide, dactinomycin
- - If radiation or chemotherapy needed:
- - Vincristine, cyclophosphamide, dactinomycin

References

Epididymitis
- Most epididymal lesions are benign and should be followed serially.
- Treatment for epididymitis is guided by risk of STIs as a source.
- Ultrasonography is important to delineate a testicular vs paratesticular origin of the mass.
- Ultrasonography can reliably differentiate malignant solid tumors from benign tumors.
- Rhabdomyosarcoma predominantly occurs in children.
EPIDIDYMITIS
Jonathan H. Huang, MD
Wayland Hsiao, MD

BASICS
DESCRIPTION
• Epididymitis is an inflammatory condition of the epididymis
  • Acute epididymitis is a clinical syndrome consisting of pain, swelling, and inflammation of the epididymis that lasts <6 wk
  • Usually infectious but occasionally inflammatory due to trauma or other cause
  • Chronic epididymitis is characterized by a >6-wk history of symptoms of discomfort and/or pain in the scrotum, testicle, or epididymis
  • Infectious epididymitis is often associated with orchitis
  • Left untreated, localized infectious epididymitis can lead to more extensive infection to include the testicle
  • Thought to be the most common cause of scrotal pain in men

EPIDEMIOLOGY (1)
Incidence
• Estimated at 1 in 100 males in the United States

Prevalence
• 42% of cases are in males 20–39 yr old
• Reported from infancy to the elderly population

RISK FACTORS
• High-risk sexual behavior (multiple sexual partners, sex without condoms)
• Poor hygiene
• Being uncircumcised
• Poor hygiene
• High-risk sexual behavior (multiple sexual partners, sex without condoms)
• Instrumentation of the genitourinary tract
• Catheterization, transurethral surgery
• Urinary tract obstruction (benign prostate hypertrophy, urethral strictures, bladder cancer, prostatic cancer)
• Amiodarone usage
• Testicular pain
• Gradually worsens in epididymitis

ASSOCIATED CONDITIONS
• Orchitis
• Hydrocele
• Immunosuppression

GENERAL PREVENTION
• Condom usage
• Proper hygiene
• Avoiding unnecessary instrumentation of the genitourinary tract

ALERT
Emergency evaluation for testicular torsion is indicated when the onset of pain is sudden, pain is severe, or the test results available during the initial examination do not support a diagnosis of infection.

DIAGNOSIS
HISTORY
• Testicular pain
• Gradually worsens in epididymitis
• Rapid onset and intense in testicular torsion
• Sexual intercourse without condom including anal receptive unprotected sex
• Instrumentation of the genitourinary tract
• Review of systems may help elucidate other causes (ie, amiodarone usage, TB, Behçet disease, sarcoidosis)
• Chronic Epididymitis Symptom Index (CESI) has been described for cases that last >3 mo

Other infectious causes:
• Bacterial
 ◦ Escherichia coli, Salmonella enterica
 ◦ Chlamydia pneumoniae
 ◦ Mycoplasma genitalium, Ureaplasma urealyticum
 ◦ Brucella abortus, Brucella canis, Brucella canis, Brucella melitensis, Brucella gormanii
 ◦ Fungal (more common with HIV)
 ◦ Cryptococcus neoformans
 ◦ Mucormycosis
 ◦ Nocardiosis
 ◦ Actinomycosis
 ◦ Tuberculosis
 ◦ Tuberculosis
 ◦ Sarcoidosis
 ◦ Trauma
 ◦ Amiodarone usage
 ◦ Antiretroviral antibodies interact with the elevated concentration of amiodarone in the epididymis, leading to inflammation
 ◦ Behçet disease
 ◦ Etiology of epididymitis is unclear
 ◦ Sarcoidosis
 ◦ Noncaseating granulomas in the epididymis lead to inflammation
 ◦ Chronic epididymitis (>6-wk duration)
 ◦ Inadequately treated acute epididymitis
 ◦ Postprostatectomy syndrome
 ◦ Reported in 1 in 100 males
 ◦ TB
 ◦ Suspected to be due to hematogenous spread; usually a chronic granulomatous reaction
 ◦ BCG treatment for superficial bladder cancer can lead to epididymitis

PHYSICAL EXAM
• Epidermal tenderness
• Positive in 90–97% of patients
• Epidemidal and constrictional testicle may be involved
• Erythema
• Spermatic cord may be involved
• Enlargement of the scrotum
• Fever
• Genital exam
• UI symptoms related to STDs
• Urinalysis
• Ulcerations from Behçet disease
• Hydrocele
• A reactive process sometimes related to the epididymal inflammation
• Prostate exam
• Rule out prostatitis, especially in males with chronic epididymitis
• Pain sign
• Used to rule out testicular torsion
• Allallowment of pain, with elevation of the testicle, is more consistent with epididymitis (negative Pain sign)
• Only positive in 8% of children with epididymitis

DIAGNOSTIC TESTS & INTERPRETATION
Lab (3)
• Used to rule in a source of infection
• Urinalysis
• Gram stain with at least 5 white blood cells (WBCs) per high power field
• Gram-negative bacilli is suggestive of E. coli infection and underlying cystitis
• Intracellular gram-negative diplococci suggests a diagnosis of N. gonorrhoeae infection
• Findings of only WBCs are suggestive of E. chaffeensis in 2/3 of cases
• Send for culture and sensitivity
• Urosepsis
• Assess for leukocyturia or at least 10 WBCs per high power field
• Urine culture (midstream clean catch)
• Send for culture and sensitivity
• C-reactive protein
• Acute phase protein that is elevated in epididymitis
• Sensitivity of 96.2%, specificity of 94.2%
• When an STD is suspected, the patient should be screened for other STDs, including human immunodeficiency virus (HIV)

Imaging (4.5)
• Color Doppler scrotal ultrasound (US)
• Hypoechoic and swelling in epididymitis
• Sensitivity of 70%, specificity of 88%
• Negative US, when positive clinical findings, should not necessarily alter management
• Decreased blood flow in testicular torsion
• Sensitivity of 100%
• Rule out testicular torsion
• Ultrasound imaging with Testicular perfusion
• High sensitivity and specificity in differentiating testicular torsion from epididymitis
• Rarely used in the United States

PHYSICAL EXAM
• Epidermal tenderness
• Positive in 90–97% of patients
• Epidemidal and constrictional testicle may be involved
• Erythema
• Spermatic cord may be involved
• Enlargement of the scrotum
• Fever
• Genital exam
• UI symptoms related to STDs
• Urinalysis
• Ulcerations from Behçet disease
• Hydrocele
• A reactive process sometimes related to the epididymal inflammation
• Prostate exam
• Rule out prostatitis, especially in males with chronic epididymitis
• Pain sign
• Used to rule out testicular torsion
• Allallowment of pain, with elevation of the testicle, is more consistent with epididymitis (negative Pain sign)
• Only positive in 8% of children with epididymitis

MEDICATION (1)

GENERAL MEASURES

Empiric therapy to treat infections tailoring therapy to age and history

For infections tailor therapy to age and history

Chronic epididymitis

Acute epididymitis

Varicocele

Testicular torsion

Testicular cancer

Spermatocele

Referred pain (inguinal hernia renal colic, aneurysm, hip pain, lower back pain)

Spermatic cord torsion

Interstitial cystitis

Chronic pelvic pain syndrome

Abscess

Possible fibrosis

Infection

Inflammation

In infants and children with epididymitis, up to 75%

Ciprofloxacin and other quinolones are no longer recommended when there are clinical signs of epididymitis and a positive urine culture.

– Levofloxacin 500 mg orally once daily for 10 days

– Ciprofloxacin and other quinolones are no longer recommended when there are clinical signs of epididymitis and a positive urine culture.

– Local heat therapy/Sitz baths

– Scrotal support

– Course of antibiotics is appropriate initially; if no improvement in symptoms, consider:

Avoid sexual activity for at least 1 wk following the initiation of treatment, especially if symptoms have not improved

Infections due to resistance

Fertility issues need to be addressed

Outcomes appear improved in the setting of posthysterectomy chronic epididymitis

– Patient needs to understand that there is only at a 10% chance of pain relief

– Outcomes appear improved in the setting of posthysterectomy chronic epididymitis

– Festivity issues need to be addressed

– Testicular denervation

– Not widely used

– Reserved for patients who failed conservative management

– Pain relief noted in 71% of cases

SECOND LINE

SURGERY/OTHER PROCEDURES

– Drainage if abscess present

– Epididymectomy

– Reserved for patients who failed conservative management

– Pain relief noted in 71% of cases

ADDITIONAL TREATMENT

Radiation Therapy

Epididymitis Image

Complementary & Alternative Therapies

FOLLOW-UP

Patient Monitoring

In men < 35 yr old STI/STD with C. trachomatis and N. gonorrhoeae are the most common organisms responsible for bacterial epididymitis.

In older men suspect coliform bacteria.

Testicular torsion needs to be ruled out in cases of acute scrotal pain (clinical exam and Doppler US as appropriate).

A54.23 Gonococcal infection of other male genital organs

N45.1 Epididymitis

CLINICAL/SURGICAL PEARLS

Clinical Pearls

In men < 35 yr old STI/STD with C. trachomatis and N. gonorrhoeae are the most common organisms responsible for bacterial epididymitis.

In older men suspect coliform bacteria.

Testicular torsion needs to be ruled out in cases of acute scrotal pain (clinical exam and Doppler US as appropriate).

EPISPADIAS

Sarah M. Lambert, MD
Pasquale Casale, MD, FACS
Paul H. Noh, MD, FACS, FAAP

DIAGNOSIS

HISTORY
- Usually recognized at birth
- Less severe forms, especially in females, may go unrecognized until the child experiences persistent urinary incontinence after toilet training or UTIs
- Urinary incontinence due to open bladder outlet and absence of urinary sphincter. The more proximal the urethral meatus, the greater the degree of incontinence
- There may be a family history of exstrophy–epispadias, although rare

PHYSICAL EXAM
- Males:
  - Displaced urogenital sinus, ranging from plans to perineal to peno-pubic region to subpubic location
  - Open urethral plate visible on dorsum of phallus
  - Divergent peno-pubic attachments due to public diastasis, resulting in splaying of corporal cavernosa and a short, pendular penis with dorsal chordee
  - 3 degrees of female epispadias, according to Davis (1)
  - Assess position of testes
  - Ventral hood of foreskin
  - Divergent peno-pubic attachments due to public diastasis
  - Open urethral plate visible on dorsum of phallus
- Females:
  - 3 degrees of female epispadias, according to Davis (1)
  - Urethral orifice appears patulous
  - Labia minora poorly developed and terminated anteriorly at clitoris
  - Vagina and internal genitalia usually normal
  - Assess position of clitoris

LABORATORY
- CBC, renal profile

Diagnostic Procedures/Surgery
- Voiding cystourethrogram to assess bladder capacity, bladder outlet, presence/absence of VUR
- Renal/bladder US to assess presence/absence of 2 kidneys and presence/absence of hydronephrosis, due to increased risk of renal agenesis, ectopic renal location, and VUR
- Urodynamic program to assess bladder capacity, bladder outlet, presence/absence of VUR

Pathologic Findings
- N/A

DIFFERENTIAL DIAGNOSIS
- Varying degrees of epispadias
- Classic bladder exstrophy

TREATMENT

First Line
- Anticholinergic therapy may help with bladder overactivity and modeling to promote increased capacity with good compliance once surgery has increased outlet resistance

Second Line
- N/A

SURGERY/OTHER PROCEDURES

Goals:
- Protection of upper tracts, including correction of VUR and maintenance of a low-pressure system
- Achieve urinary continence
- Reconstruction of external genitalia for optimal functional and cosmetic results

Type of Surgery
- Bladder closure between 3 to 6 m of age. Patient is left with an epispadias
- Can also be done as a single stage with bladder closure and urethral reconstruction known as the “Complete Primary Repair of Exstrophy.” Higher incidence of glanular loss than staged repair
- Ureterectomies are needed if the public diastasis is 4 cm or greater on plain x-ray. It was once thought that if the surgery was done in the 1st 48 hr of life that ureterectomies are not needed. Current management favors ureterectomies to maximize continence
- Patients need to be immobilized after surgery to allow pelvic bone healing if osteotomies are needed

Imaging
- Plain x-ray to assess orientation of pelvic bones; osteotomies should be done if public diastasis is > 4 cm
- Renal/bladder US to assess presence/absence of 2 kidneys and presence/absence of hydronephrosis, due to increased risk of renal agenesis, ectopic renal location, and VUR

BASICS

DESCRIPTION
- Congenital anomaly characterized by a dorsal opening of the urethra, resulting in dorsal chordee and widely displaced corporeal bodies
- Often associated with the so-called “exstrophy–epispadias complex” – a wide spectrum of abnormalities that can include classic bladder exstrophy, epispadias, and cloacal exstrophy
- Each of these anomalies is considered to arise from the same basic embryologic defect

EPIDEMIOLOGY

Incidence
- 1 in 117,000 newborn males (1)[A]
- 1 in 484,000 newborn females (1)[A]
- Males: 1 in 117,000 newborn males (1)[A]
- Females: 1 in 484,000 newborn females (1)[A]

Prevalence
- N/A

RISK FACTORS
- N/A

PATHOPHYSIOLOGY
- On the same spectrum of exstrophy
- Failure of medial migration of mesenchyme between the ectodermal and endodermal layers of the cloacal membrane due to premature rupture of the cloacal membrane
- The mesenchyme that forms the genital tubercles at the 5th wk of gestation fails to migrate completely toward the midline, resulting in a defect in the dorsal urethral wall

ASSOCIATED CONDITIONS
- Exstrophy
- Urinary incontinence
- VUR: Incidence of 30–75% (1)
- Inguinal hernias: Incidence of 33% (1)
- Failure of medial migration of mesenchyme between the ectodermal and endodermal layers of the cloacal membrane
- On the same spectrum of exstrophy–epispadias, imperforate anus most common
- Concomitant colorectal anomalies with 1.8%–2.8% concomitant renal anomalies, duplicated collecting system most common
- Congenital anomaly characterized by a dorsal opening of the urethra, resulting in dorsal chordee and widely displaced corporeal bodies

GENETIC
- None identified

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Males:
  - Displaced urogenital sinus, ranging from plans to perineal to peno-pubic region to subpubic location
  - Divergent peno-pubic attachments due to public diastasis, resulting in splaying of corporal cavernosa and a short, pendular penis with dorsal chordee
- Females:
  - 3 degrees of female epispadias, according to Davis (1)
  - Urethral orifice appears patulous
  - Place is left with an epispadias

LABORATORY
- CBC, renal profile

SURGERY/OTHER PROCEDURES

Goals:
- Protection of upper tracts, including correction of VUR and maintenance of a low-pressure system
- Achieve urinary continence
- Reconstruction of external genitalia for optimal functional and cosmetic results
- First stage:
  - Bladder closure between 3 to 6 m of age. Patient is left with an epispadias
  - Can also be done as a single stage with bladder closure and urethral reconstruction known as the “Complete Primary Repair of Exstrophy.” Higher incidence of glanular loss than staged repair
  - Ureterectomies are needed if the public diastasis is 4 cm or greater on plain x-ray. It was once thought that if the surgery was done in the 1st 48 hr of life that ureterectomies are not needed. Current management favors ureterectomies to maximize continence
- Patients need to be immobilized after surgery to allow pelvic bone healing if osteotomies are needed
**PROGNOSIS**

- Continence rates after bladder neck reconstruction range from 70% to 87% [2,5].
- Satisfactory condoms after penile reconstruction range from 50% to 85% (8,17).
- Erectile function is almost universally preserved.
- The ability to participate in satisfactory intercourse and to have children is difficult to assess, as this requires long-term follow-up. Most reports aim to indicate the majority of patients can have intercourse and many males have even fathered children.

**COMPLICATIONS**

- The most common is fistula formation, with an incidence of 4–40% after urethropasty in males, although many of these will close spontaneously (2,4,7).
- Other less common complications are stricture, meatal stenosis, wound infection, diverticulum, and urothelial obstruction.
- If there is tension on the closure, dehiscence is a major complication that might result.

**FOLLOW-UP**

**Patient Monitoring**

- **After epispadias repair:**
  - Remove urethral catheter 1–2 wk after surgery
  - Regular urology to assess urethra and bladder capacity
  - Regular upper tract monitoring with urodynamics US in cases of persistent incontinence or infection

  **After bladder neck repair:**
  - Urodynamics may be necessary with cystometrogram and urethral pressure profilometry
  - Continuation of prophylactic antibiotics until PVRS are minimal
  - Can remove SP tube once PVRS are minimal
  - Can remove urethral catheter 1–2 wk after surgery
  - Urodynamics may be necessary with cystometrogram and urethral pressure profilometry
  - Can remove SP tube once PVRS are minimal

See Also (Topic, Algorithm, Media)

- Epispadias in HPG
- Exstrophy, Bladder (Classic Exstrophy)
- Exstrophy, Clival
- Exstrophy-Epispadias Complex

**ICD9**

- 752.62 Epispadias
- 752.5 Exstrophy of urinary bladder
- 752.8 Other specified anomalies of bladder and urethra

**ICD10**

- Q64.0 Exstrophy
- O64.0 Epispadias
- O64.10 Exstrophy of urinary bladder, unspecified

**CLINICAL/SURGICAL PEARLS**

- Female epispadias is not well recognized. It often presents after birth because of complaints of incontinence.
- Antenatal ultrasound may be suggestive of exstrophy-epispadias complex. Findings of abnormal genitalia, low set umbilical cord, inability to identify bladder on ultrasound.
ASSOCIATED CONDITIONS

Treatment effects are generally dependent upon the modality used and are discussed elsewhere.

GENERAL PREVENTION

• Pelvic surgery/RP:
  – Cavernous nerve sparing surgery
  – Sparing of accessory pudendal arteries intraperitoneally
  – RT:
  – Reducing volume of tissue irradiated is postulated to reduce likelihood of ED
  – No definitive evidence supporting use of intensity-modulated radiation therapy (IMRT), RT, or proton beam RT to reduce ED
  – Treatment plans limiting RT to the corpora cavernosa may have a beneficial effect
  – Penile rehabilitation:
    – Signals from studies suggesting early rehabilitation (phosphodiesterase type 5 inhibitors (PDE5i), intracavernosal injections) can impact postoperative erectile status after RP and RT
    – Goals: Cavernosal oxygenation, preservation of endothelial function, prevention of corporal smooth muscle fibrosis.
    – Optimal regimen for rehabilitation is not understood

DIAGNOSIS

HISTORY

• Medical history:
  – Risk factors for general ED
  – Cardiovascular disease
  – Diabetes mellitus
  – Smoking
  – Hypertension
  – Depression
  – Alcoholism
  – Surgical history
  – Type and date of surgery
  – Nerve sparing status (if RP or radical cystectomy)
  – Type and date of surgery
  – Radiation history
  – Dose, template, radiation modality, and date
  – Use of ADT
  – Radiation history
  – Dose, template, radiation modality, and date
  – Use of ADT
  – Radiation history
  – Dose, template, radiation modality, and date
  – Use of ADT

PHYSICAL EXAM

• General physical exam
  – Medical history
  – Presence of nocturnal erections
  – Consistency of erectile quality
  – Onset and severity of ED
  – Validated questionnaires, ie, International Index of Erectile Function (IIEF)
  – Peak systolic velocity < 30 cm/s indicative of CVOD
  – Peak systolic velocity > 30 cm/s indicative of arterial insufficiency
  – Testicular volume and consistency as screening for hypogonadism

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Generally noncontributory.
  – If evidence of hypogonadism, check early morning serum testosterone.
  – Testosterone levels < 300 ng/dL

Imaging

• Duplex Doppler ultrasound of the penis
  – Can be used to evaluate for presence of vasculogenic ED
  – Peak systolic velocity < 30 cm/s indicative of arterial insufficiency
  – Testicular volume < 5 cm³ indicative of CVOD

Diagnostic Procedures/Surgery

• Pathologic findings

DIFFERENTIAL DIAGNOSIS

• Hypoactive sexual desire disorder
  – Medication induced: Antihypertensives, psychotropics, antidepressants
  – Neurogenic ED
  – Psychogenic ED
  – Vascular ED

TREATMENT

GENERAL MEASURES

• Perform cardiovascular risk assessment to evaluate fitness for sexual activity prior to treatment.
  – Patient and partner should be informed of relevant treatment options, risks, and benefits.

MEDICATION

First Line

• PDE5i (USA)
  – Likely to be ineffective immediately after surgery given cavernosal nerve injury
  – Daily dosing frequently used in rehabilitation regimens
  – When used on-demand only, decreased response noted 2–3 yr after RT

• Medications:
  – Sildenafil 50–100 mg: Onset 15–60 min, duration of action 4 hr
  – Vardenafil 10–20 mg: Onset 15–60 min, duration of action 4–8 hr
  – Tadalafil 10–20 mg: Onset 15–120 min, duration of action 24–36 hr
  – Avanafil 100–200 mg

• Combinations to PDE5i use:
  – Absolute contraindications: Use of nitrites
  – Sildenafil, Tadalafil, Vardenafil: Should be postponed for 4 hr after taking the nitric oxide antagonists
  – Vardenafil: Should not be taken with type 1A or type 3 sodium channel blockers

• Side effects: All associated with headache, dyspepsia, facial flushing

• Sildenafil, Tadalafil: Blurred vision—reacts with PDE6 in retina
Erectile Dysfunction, Following Pelvic Surgery or Radiation

Second Line
- Intracavernosal Injection therapy
  - Highly effective with up to an 85% response rate post-RT (SEC)
  - Risks include priapism, penile pain, ecchymosis
  - Used in a variety of formulations
  - Single agent: Prostaglandin E1
  - Bimix: Papaverine and phentolamine
  - Trimix: Papaverine, phentolamine, and prostaglandin E1
- Intravesical prostaglandin E1 suppository (MUSE)
  - Variable efficacy
  - Penile pain frequently reported, especially in the immediate postoperative period

Surgery/Other Procedures
- Vacuum constriction devices
  - Low patient satisfaction given cumbersome application
- Penile prosthesis implantation
  - Definitive therapy for patients failing or refusing 1st- and 2nd-line treatments
  - Generally, postponed until 2 yr post-RT as regeneration of cavernous nerves during this time may preclude need for surgical therapy
  - High patient satisfaction in appropriately selected population
- Implant infection and malfunction risk must be discussed with patient preoperatively

Additional Treatment
Radiation Therapy
- 1st- and 2nd-line treatments
  - Limited data on combining modalities has been reported
- Level 3 evidence: PDE5i ± either transurethral or intracavernosal injection therapy generates better efficacy than either monotherapy alone
- Level 4 evidence: Enhanced efficacy with the combination of vacuum-erection therapy ± either PDE5i or transurethral PGE1 or intracavernosal injection therapy

Complementary & Alternative Therapies
- Data does not support use of trazodone, yohimbine, and herbal therapies. These medications are not recommended for use in ED by the American Urological Association
- Testosterone therapy
  - Noted to be strongest predictor of patient satisfaction after prostate cancer therapy, particularly in patients with a history of prostate cancer

Prognosis
- Improvement in erectile function can be noted after pelvic surgery, with maximal improvement noted between 18 and 24 mo postoperatively.
- Low likelihood of improvement in erectile quality after 2 yr postoperatively.
- Nadir of erectile function 3 to 5 yr after RT.
- Penile rehabilitation likely improves the prognosis of postsurgical/post-RT ED. Definitive data are pending.

Complications
- Significant effects on patient quality of life
- Noted to be strongest predictor of patient satisfaction after prostate cancer therapy
- Depression

Follow-Up
- Variable dependent upon patient response to treatment.
- Close follow-up is recommended in patients on rehabilitation protocols to evaluate for erectile recovery.

Patient Resources

Additional Reading

See Also (Topic, Algorithm, Media)
- Erectile Dysfunction/Impotence, General Considerations
- Penile Doppler Ultrasound, Indications and Parameters
- Penile Rehabilitation

Codes
ICD9
- 527.84 Impotence of organic origin
- N52.31 Erectile dysfunction following radical prostatectomy
- N52.32 Erectile dysfunction following radical cytoreduction
- N52.39 Other post-surgical erectile dysfunction

Clinical/Surgical Pearls
- ED after pelvic surgery and RT is highly prevalent and frequently underdiagnosed in physicians, marketing materials.
- ED after pelvic surgery is immediate in onset with 18–24 mo time to maximal recovery. 
- ED after RT has a minimal onset, with nadir of erectile function at 9–12 mo post-RT.
- Data on penile rehabilitation is conflicting but increasingly shows an improvement in posttreatment erectile recovery.
- The majority of postpelvic surgery/RT ED patients are effectively treated with PDE5i in intracavernosal injection therapy.
Erectile Dysfunction/Impotence, General Considerations

Trinity J. Bivalacqua, MD, PhD

RISK FACTORS

Prevalence

EPIDEMIOLOGY

Incidence

• Crude incidence: 26 cases/1,000 man years
  – Incidence increases with each decade above 40
  ◦ 12 cases/1,000 man years: 40–49 yr
  ◦ 30 cases/1,000 man years: 50–59 yr
  ◦ 46 cases/1,000 man years: 60–69 yr

Prevalence

• Increases universally with age and medical comorbidities (cardiovascular disease, hypertension, smoking, inactivity, obesity)
  – Prevalence by age
    ◦ Below age 40: 1–9%
    ◦ 40–49 yr: 10–20%
    ◦ 50–69 yr: 20–40%
    ◦ >70 yr: 50–75%

PATHOPHYSIOLOGY

Mechanism of erection

– Relaxation of cavernosal smooth muscle (contracted in flaccid state inhibiting inflow of blood)
  ◦ Mediated by NO release from pelvic nerves and endothelial cells
  ◦ Increased cyclic GMP (cGMP) and cyclic AMP (cAMP) trigger signaling pathways leading to decreased intracellular calcium causing smooth muscle relaxation, increased penile blood flow, and tumescence
  ◦ Smooth muscle relaxation further promoted due to inhibition of rho-kinase
  ◦ Veno-occlusive mechanism prevents outflow of blood from penis and maintains erection

CASES

– Associated with 14 times increased risk of cardiovascular morbidity and mortality
  – Cardiovascular disease (hypertension, hyperlipidemia, peripheral vascular disease)
  – Lower urinary tract symptoms/Benign prostatic hyperplasia (BPH)

ASSOCIATED CONDITIONS

– Chronic renal failure, chronic liver disease
– Endocrine disorders (hypogonadism, Cushing disease)

– Prior abdominal/pelvic surgery, radiation, trauma
  – Plasmod, Peyronie disease
  – Neurologic disease (Parkinson disease, dementia, stroke)
  – Depression/psychological disorders

– Long distance cycling
– Smoking

– Medications
  ◦ Antihypertensives (thiazide diuretics, β-blockers, α2 agonists)
  ◦ ACE inhibitors, angiotensin receptor blockers, and calcium channel blockers cause less ED by improving erectile function
  ◦ Psychotropics (monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, lithium)

– Antidepressants
  – Antidepresants (clomipramine, sertraline, paroxetine, marijuana)
  – Tobacco smoking

DIAGNOSIS

HISTORY

– Medical history—comorbid conditions, medications, alcohol, tobacco, recreational drug use, history of cycling
– Surgical history
– Psychosocial history
  – Status of current relationship
  – Level of libido/interest in sex
  – Quality of erection
  – Duration of ED
  – Onset of ED (sudden vs. gradual)
– Presence of nocturnal or morning erections
– Presence of penile curvature, plaque, pain
– International Index of Erectile Function

PHYSICAL EXAM

– Neurologic: Stroke, TIA, CNS disease; visual field defects, neuropsych, perimodal vision
– Endocrinologic: Atrophic testes, gynecomastia, loss of secondary sexual characteristics
– Cardiovascular: Blood pressure, femoral/pedal pulses, lower extremity ischemia
– Penile: Curvature, Peyronie disease plaques
– Rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

– Complete blood count
– Serum chemistries
– Fasting glucose level, hemoglobin A1C
– Lipid profile
– Serum total testosterone
– Thyroid function tests (optional)
– PSA (suspect prostate pathology)
– Urinalysis (glucose as indicator of diabetes)

Imaging

– Duplex penile ultrasound—most reliable and least invasive modality for assessing ED
– Provides imaging evaluation and quantification of penile blood flow

ASSOCIATED CONDITIONS

– Atherosclerosis
  – Diabetic mellitus
  – Hypertension, stroke
  – Depression
  – Parkinson disease, multiple sclerosis
  – Psoriasis
  – Peyronie disease
  – Prostate cancer

GENERAL PREVENTION

– Avoidance of tobacco use
– Optimal medical management of common associated conditions
  – Increase exercise/weight loss
  – Split bicycle seat for long-distance cycling

Genetics

– Several gene polymorphisms linked with ED
  – Angiotensin-converting enzyme (ACE) polymorphisms may be risk factors for vasculogenic ED and endothelial nitric oxide synthase (eNOS) polymorphisms alone or in combination with other genetic polymorphisms implicated in ED

BASICS

DESCRIPTION

Consistent or recurrent inability to attain and/or maintain an erection sufficient for satisfactory sexual activity

ASSOCIATED CONDITIONS

– Medications
  – Smoking
  – Long-distance cycling
  – Depression/Psychological disorders
  – Neurologic disease (Parkinson disease, dementia, prior stroke)
  – Priapism, Peyronie disease
  – Prior abdominal/pelvic surgery, radiation or trauma
  – Endocrinopathies (hypogonadism, Cushing disease)
  – Lower urinary tract symptoms/Benign prostatic hyperplasia (BPH)

RISK FACTORS

Probability of ED increases with presence of each risk factor

– Diabetes mellitus
  – Presence of ED 3 times higher in diabetic men

– ED occurs at earlier age and increases with disease duration

– Associated with 14 times increased risk of cardiovascular morbidity and mortality

– Cardiovascular disease (hypertension, hyperlipidemia, peripheral vascular disease)

– Lower urinary tract symptoms/Benign prostatic hyperplasia (BPH)

– Chronic renal failure, chronic liver disease

– Endocrine disorders (hypogonadism, Cushing disease)

– Prior abdominal/pelvic surgery, radiation, trauma

– Plasmod, Peyronie disease

– Neurologic disease (Parkinson disease, dementia, stroke)

– Depression/psychological disorders

– Long distance cycling

– Smoking

– Medications

– Antihypertensives (thiazide diuretics, β-blockers, α2 agonists)

– ACE inhibitors, angiotensin receptor blockers, and calcium channel blockers cause less ED by improving erectile function

– Psychotropics (monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, lithium)

– Antidepressants

– Antidepresants (clomipramine, sertraline, paroxetine, marijuana)

– Tobacco smoking
Erectile Dysfunction/Impotence, General Considerations

**Differential Diagnosis**

Psychogenic erectile dysfunction, depression, possible early sign of cardiovascular disease

**Treatment**

**General Measures**

- Treatment choice should be made among physician, patient, and partner after evaluation of risk/benefit of all treatment choices
- Cardiovascular risk assessment should be performed before initiating therapy
  - Low risk: Asymptomatic, <3 risk factors—may proceed with medical therapy
  - Intermediate risk: Asymptomatic, 3-5 risk factors, stable angina, or mild heart failure—requires full cardiovascular assessment to reclassify as high vs. low risk
  - High risk: Unstable angina, recent myocardial infarction, advanced heart failure or valvular disease—defer until cardiac condition stabilized

**Medication**

- **First Line**
  - PDE5 inhibitors (PDE5i): Inhibit breakdown of cGMP promoting smooth muscle relaxation
    - Sildenafil 50–100 mg: Onset 15–60 min, duration of action 4 hr
    - Vardenafil 10–20 mg: Onset 15–60 min, duration of action 2–8 hr
    - Tadalafil 10–20 mg: Onset 15–120 min, duration of action 24–36 hr
    - Avanafil 100–200 mg
  - Combinations to PDE5i use:
    - Absolute contraindications: Use of nitrates
    - Should be postponed for 4 hr after taking inhibitors or α-adrenergic antagonists

  - **Second Line**
    - Intracavernous injection therapy
    - Mechanism: Self-injection of vasoactive agent into corpora cavernosa producing rapid erection
    - Drugs:
      - Alprostadil (PGE1)
      - Bimane: Papaverine and phentolamine
      - Trimix: Papaverine, phentolamine, and prostaglandin E1
    - Side effects: Fibrosis, priapism, painful erection, hematoma
    - Complications: Monoxide oxide medication usage, decreased manual dexterity
    - Efficacy: 80–90% effective in wide range of patients
      - Intracutaneous therapy
      - MUSE (Medicated urethral system for erection)
    - Mechanism: Insertion of abbot containing pellet into distal urethral, absorbed into corpora cavernosa production erection within 30 min
    - Side effects: Penile ischemia, pain, abnormal color of penis

**Surgery/Other Procedures**

- **IP**
  - Indications: Failed 1st- and 2nd-line pharmacotherapy or vacuum device treatment
  - Mechanism: Definitive ED treatment with placement of inflatable cylinders into corpora cavernosa
  - Complications: Infection (<1%), erosion (<5%), mechanical malfunction (5–10%)
  - Penile neurovascularization
    - Reserved for select young patients with clearly documented arterial occlusion

**Additional Treatment**

**Radiation Therapy**

**Additional Therapies**

- Psychosocial therapy: Referral for sex therapy in patients with psychogenic ED
- Cognitive behavioral intervention identifies sexual stressors and refines maladaptive thought processes

**Complementary & Alternative Therapies**

- No FDA-approved dietary supplements or herbal medications for ED but ginseng, ginko biloba, red ginseng, yohimbine reportedly improve ED

**Ongoing Care**

- Excellent if reduction of cardiovascular risk factors, weight loss, exercise, smoking cessation

**Complications**

- N/A

**Follow-Up**

**Patient Monitoring**

- Patients to be reviewed periodically with follow-up considerations:
  - Progress to initial therapy
  - Need for dose titration
  - Patient education on proper medication use (specific PDE5i on empty stomach, use of local injection therapy)
  - Need for progression to 2nd-line therapy/surgery based on therapeutic effectiveness and patient satisfaction

**Patient Resources**

**References**

**Additional Reading**

See Also (Topic, Algorithm, Media)

- Erectile Dysfunction Algorithm

- Erectile Dysfunction, Following Pelvic Surgery or Radiation

- Erectile Dysfunction/Impotence, General Considerations

- Penile Rehabilitation

**Additional Pearls**

- ED is a symptom of multiple underlying diseases that affect the following: penis nerve, artery, endothelial or smooth muscle function
- Cardiac risk assessment should occur prior to initiation of therapy
- Surgical therapy (penile prosthesis) is an essential therapy when medical treatment has failed or is contraindicated.
EXSTROPHY, BLADDER (CLASSIC EXSTROPHY)
Grahame H.H. Smith, MBBS

DIAGNOSIS

HISTORY

- Any family history of exstrophy

PHYSICAL EXAM

- Bladder exposed on abdominal wall
- Bladder plate size
- Lateral ureteric orifices
- Males have an open bladder neck and prostate, the short and broad phallus is open dorsally with dorsal chordee
- Females have an open bladder neck and urethra, bifid clitoris lateral to urethra and anteriorly situated vagina
- Rectus diastasis with external rotation of pelvis
- Low-set umbilicus with foreshortened distance to pubis
- Public dialogue with external rotation of pelvis

DIAGNOSTIC TESTS & INTERPRETATION

- Antenatal ultrasound
- Renal ultrasound
- Blood type and cross-match in preparation for surgery

PHYSICAL EXAM

- Any family history of exstrophy

TREATMENT

GENERAL MEASURES

- Anterograde
  - Consider MRI assessment and karyotyping
- Options for termination may be discussed
- Immediate postnatal care
- 2-0 silk suture on abdominal cord as close to abdominal wall as possible
- Cover bladder with a nonadherent dressing
- Irrigate with normal saline and apply a new dressing with each diaper change

SURGERY/OTHER PROCEDURES

- Ideally the exstrophy is closed on next elective list with two senior staff in attendance
- Requires an adequate bladder plate but the minimum size is not defined
- If unable to easily approximate pubis, then may need pelvic osteotomy
- Pelvic osteotomy may reduce the incidence of delirium and subsequent prolapse in females
- Avoid latex exposure to prevent latex allergy

DIFFERENTIAL DIAGNOSIS

- Bladder exstrophy
- Omphalocele
- Gastrochisis
- Epispadias

BASICS

DESCRIPTION

- Classic bladder exstrophy is a major genitourinary anomaly characterized by the bladder lying open on the abdominal wall with an associated lower midline abdominal wall hernia. The defect extends from the umbilicus to the distal end of the phallus, resulting in concurrent epispadias in males and a bifid clitoris in females.
- Classic exstrophy is considered midway in severity between cloacal exstrophy and epispadias, as part of exstrophy–epispadias complex.

Epidemiology

- Incidence
  - 1 in 10,000–50,000
  - Male > Female (2:1)

- Prevalence
  - N/A

RISK FACTORS

- Genetics
  - Multifactorial etiology without definite genetic link
  - 1st theory postulates that an incomplete ingrowth of mesoderm is unable to reinforce cloacal membrane, which results in premature rupture and subsequent failure to develop ectoderm and mesoderm. The timing of the rupture determines cloacal (earlier) vs. classic exstrophy (later)
  - 2nd theory describes an overgrowth of cloacal mesenchymal tissue. Bladder smooth muscle cells in exstrophy patients show lower intracellular calcium concentrations and enhanced migration

ASSOCIATED CONDITIONS

- Usually healthy without any other major organ system defects
- Subsequent inguinal hernia common
- Rarely may be associated with duplication of bladder or urethra, colorectal abnormalities (2%), duodenal and palate, subsequent testis tumors
- In contrast, classic exstrophy has much more extensive anomalies

GENERAL PREVENTION

N/A

DIFFERENTIAL DIAGNOSIS

- Bladder exstrophy
- Omphalocele
- Gastrochisis
- Epispadias

DISCUSSION

PATHOPHYSIOLOGY

- Risk in sibling is 1 in 100; risk in offspring is 1 in 70

- Male
  - 1 in 10,000–50,000

- Female
  - 19q13.31–41, and 22q11.21 may harbor genes associated with exstrophy

- Cloacal exstrophy
  - Associated with p63 gene dysregulation

- Classic bladder exstrophy
  - Considered midway in severity between cloacal exstrophy and epispadias (later)

- Risk in sibling is 1 in 100; risk in offspring is 1 in 70

- Male
  - 1 in 10,000–50,000

- Female
  - 2:1

- 1st theory postulates that an incomplete ingrowth of mesoderm is unable to reinforce cloacal membrane, which results in premature rupture and subsequent failure to develop ectoderm and mesoderm. The timing of the rupture determines cloacal (earlier) vs. classic exstrophy (later)

- 2nd theory describes an overgrowth of cloacal mesenchymal tissue. Bladder smooth muscle cells in exstrophy patients show lower intracellular calcium concentrations and enhanced migration
ADDITIONAL TREATMENT

ADDITIONAL THERAPIES

Radiation Therapy
N/A

Additional Therapies
- Delayed closure in the case of a late presentation
- All need osteotomy with option of external fixation
- Inadequate bladder plate
  - Delay closure with osteotomies, once adequate
  - If remains inadequate consider augmentation at time of closure
- Postoperative
  - Ensure maximal urinary drainage with ureteric stents, suprapubic tube, and urethral catheter
  - With or without pelvic immobilization (traction, Buck, Bryant, Mermaid dressing, spica cast)
  - Optimal duration of immobilization not established
  - Remove stents one at a time; suprapubic only removed after ensuring appropriate bladder emptying

Complementary & Alternative Therapies
N/A

ONGOING CARE
- Subsequent operative treatment options:
  - Bladder neck plasty (failure rate 50%)
  - Bladder neck closure (failure rate 2%) with augmentation and Mitrofanoff conduit
  - Ureterosigmoidostomy (plus or minus Mainz II pouch)
  - Umbilicoplasty
  - Radial forearm flap phalloplasty (males)
  - Vaginoplasty, clitoroplasty (females)

PROGNOSIS
- Life expectancy normal
- Urinary continence in 50–90%; definition of continence disputed; most common definition of continence is dry with voiding or catheterization every 3 hr
- May require multiple surgeries
- Quality of life scores are less than the normal.
- Functional results seem to be the most likely predictive factor of health-related QOL score

COMPLICATIONS
- Failure of primary closure: 10%
- Failure to store (urinary incontinence secondary to incompetent outlet plus or minus poor bladder compliance)
- Failure to empty (after closure or after bladder neck procedure)
- Upper tract damage and renal failure due to high bladder pressures and/or high outlet resistance
- Developmental psychopathology

- Male: Infertility, retrograde ejaculation, urethrocystourethrectomy fistula, loss of phallus (complete penis disassembly, Kelly repair), incontinence, testis tumors
- Female:
  - Vaginal genitus, requiring vaginoplasty
  - Degree of bladerness association with risk of uterine prolapse
  - Enterocystoplasty may lead to false-positive pregnancy test
  - Normal fertility possible, Cesarean delivery suggested
  - Increased risk of adenocarcinoma of bladder
  - Increased risk of cutaneous adenocarcinoma after urotoagmosidotony

FOLLOW-UP
- After discharge:
  - Antibiotic prophylaxis to prevent urinary tract infections
  - Regular ultrasound to assess for hydronephrosis, residual volume, and bladder volume
  - Vaginoplasty, clitoroplasty (females)

Patient Monitoring
- Yearly colonoscopy starting 10 yr after ureterosigmoidostomy

Patient Resources

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Epispadias
- Exstrophy, Cloacal
- Exstrophy–Epispadias Complex
- Exstrophy, Bladder (Classic Exstrophy) Images

CODES
- ICD9
  - 753.5 Exstrophy of urinary bladder
  - Q64.11 Supravesical fissure of urinary bladder
  - Q64.19 Other exstrophy of urinary bladder

- ICD10
  - Q64.11 Supravesical fissure of urinary bladder
  - Q64.19 Other exstrophy of urinary bladder

CLINICAL/SURGICAL PEARLS
- Achieving normal urinary continence with normal voiding after repair is uncommon. It is almost always possible to achieve continence if the patient is willing to undertake clean intermittent catheterization.
- Males will tend to be unhappy about the length of their penis. However, what they lack in length they gain in width.
- For the inexperienced clinician it is sometimes difficult to identify the gender of a newborn baby with bladder exstrophy. Boys almost always have bilateral palpable gonads.

147
EXSTROPHY, CLOACAL

Jason C. Fisher, MD
Harry P. Koo, MD, FAAP, FACS

ASSOCIATED CONDITIONS
- Upper gastrointestinal anomalies:
  - Unilateral renal agenesis (33%)
  - Pelvic kidney (33%)
  - Horseshoe kidney
  - Fusion anomalies
- Lower gastrointestinal anomalies:
  - Separation of or absence of distal ileum/colon
  - Unsegmented rectum/colonic/ileal hernias
  - Urinary and vaginal duplication anomalies
- Genitourinary anomalies:
  - Omphalocele (88–100%)
  - Short gut (20%; cause of major morbidity)
  - Intestinal malrotation
  - Intestinal duplication anomalies
- Skeletal anomalies:
  - Cerebral palsy
  - Increased intracranial pressure
  - Mental retardation
- Soft tissue anomalies:
  - Impaired continence, ambulation, erectile function
- Musculoskeletal anomalies:
  - Scoliosis
  - Hips subluxation and acetabular dysplasia
  - Lower limb anomalies
- Other anomalies:
  - Irritable bowel syndrome
  - Asthma

PATHOPHYSIOLOGY
- Disrupted cellular proliferation and apoptosis of dorsal cloacal wall and hindgut
- Disruption of the mesenchyme—this disrupts the renal tubules
- Diaphragm (82%)

PHYSICAL EXAM
- Classic collection of findings include:
  - Exstrophy of the bladder
  - Complete pelvic separation
  - Wide pubic diastasis
  - Cecal state varied between 2 hemibladders
  - Blind-ending hindgut; no well-formed colon
  - Omphalocele

TREATMENT
- Thorough assessment for associated anomalies (see “Associated Conditions”):
  - Spinal and vertebral defects
  - Lower extremity malformations
  - Renal and bladder anomalies
  - Presence of severely affected viscera
- Detailed exam of exstrophy
  - Marked: Divided corpus cavernosum and glans
  - Females: Divided clitoris, duplicated vagina
  - Additional müllerian anomalies
- Identification of external orifices: Two exstrophic hemibladders are on either side of the exstrophied intestinal segment. Each half usually drains the ipsilateral vertebral body
- Identification of intestinal orifices: Appendix, hindgut, jejunum (often prolapsed)

DIFFERENTIAL DIAGNOSIS
- Unique appearance makes it unlikely to confuse with other conditions
- Extends along EEC spectrum
- Consider associated bladder exstrophy, giant isolated omphalocele, large epispadias

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - CBC, basic metabolic panel
  - At risk for nonimmune metabolic acidosis due to absorption of urine chloride by intestinal mucosa
  - Type and cross blood for surgery
- Imaging:
  - Plain CXR, sacral and spinal x-rays
  - Ultrasound of abdomen, kidneys, head, spine
  - Consider MRI to detect occult spinal lesions if no obvious dysraphism and US nondiagnostic
- Skeletal and bony films of pelvis and lower extremities as needed

HISTORY (ANTENATAL)
- Major diagnostic criteria (210):
  - Nephromegaly (91%)
  - Large midline infraumbilical anterior abdominal wall defect or cystic anterior abdominal wall structure (82%)
  - Omphalocele (77%)
  - Lumbar myelomeningocele (68%)

PHYSICAL EXAM
- The classic collection of findings include:
  - Exstrophy of the bladder
  - Complete pelvic separation
  - Wide pubic diastasis
  - Cecal state varied between 2 hemibladders
  - Blind-ending hindgut; no well-formed colon
  - Omphalocele
Surgical pitfalls to avoid:

- Stage 3 involves procedures aimed at continence
- Multistage approach (3): Creates classic bladder exstrophy repair at 48–72 hrs of life if stable
- Open spinal anomaly: Prompt neurosurgical repair
- Generally not candidates for epidural anesthesia due
- IVF support: Adjust for fluid losses across
- – Primary perineal pull-through of the hindgut (can
- – Excising/discarding the hindgut even if short
- – Excising/discarding diminutive male phallic
- – Overaggressive closure of a large omphalocele
- – Gynecologic issues after onset of menarche
- – Ambulation impairments
- – Urinary continence: Rarely achieved; dependent
- – Important to avoid using any bowel for GU
- – 30–50% will have failure to thrive before age 5
- – Consider gastrostomy tube placement and/or
tunneled central line during initial repair if patient
appears at risk for short gut syndrome

Complementary & Alternative Therapies

- Multistage approach vs. single stage
- Single-stage approach (48): In highly select
patients, can proceed with bladder and abdominal
wall closure and phalic reconstruction which may
avoid ostomies, minimize bladder scarring. Otherwise,
Stage 2 is performed in late infancy, mirroring a classic bladder exstrophy repair:
- Mobilize bladder plate and posterior urethra
depth into perineum. Voids incontinent bladder.
- Orchiopexy with repair of inguinal hernias
- Reconstruct gender-based external genitalia
- Pubic reapproximation +/- pelvic bone osteotomies with fixation and traction for
4–6 wk

- Stage 3 involves procedures aimed at continence and genital cosmesis and is addressed in older
children, often involving bladder augmentation and catheterizable conduits
- Surgical pitfalls to avoid:
  - Injury to ureteral orifices. Place stents
  - Overaggressive closure of a large omphalocele
defect leading to compartment syndrome
  - Excising/discarding diminutive male phallic
remnants and assigning female gender. Coronal
wall and still occurs with unclear long-term
correlation.
  - Excising/discarding the hindgut even if short
  - Primary perineal pull-through of the hindgut (can
be performed in highly select patients)

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies
- Large omphalocele: Not amenable to primary
closure can be treated with Salameh-mediated
epithelialization of cut followed by delayed closure,
or by excision of sac and placement of a silo with
gradual staged reduction of sac
- Consider gastrostomy tube placement and/or
tunneled central line during initial repair if patient
appears at risk for short gut syndrome

Ongoing Care

PROGNOSIS
- Survival >95% over last 20 yr
- Nutrition and growth is the most important
determinant of early survival and mortality
- 30–50% will have failure to thrive before age 5
- Important to avoid using any bowel for GU
reconstruction procedures until child is thriving
- After 3 yr, quality-of-life issues outweigh nutritional
concerns
- Urinary continence: Rarely achieved; dependent
on a compliant reservoir and continent
catheterizable conduit
- Fecal continence: Usually managed by enema
regimen, rarely are perineal pull-through
performers associated with any continence
- Gender assignment and reconstruction, especially
for genetic males raised as females
- Ambulation impairments
- Gynecologic issues after onset of menarche
- Large urinary problems

Complications
- Infection and breakdown of repair
- Abdominal compartment syndrome
- Short gut syndrome
- Vasovagal reflex and hypotension
- Hypochromic-type enterocolitis in the dysmotile
hindgut, even after colostomy formation

Follow-up
- Requires a multidisciplinary team (see “Diagnosis”) to
coordinate regular follow-up through all stages of
surgical repair, with careful attention to nutrition and
growth in infancy, and both surgical and psychological
support for the multiple quality of life issues which
begin in childhood and persist into adulthood

- Urinary Bladder (Classic Exstrophy)
- Exstrophy, Cloacal Images

Codes
- ICD9 753.5 Exstrophy of urinary bladder
- ICD10 Q64.12 Cloacal exstrophy of urinary bladder
- ICD10 Q64.12 Cloacal exstrophy of urinary bladder

Clinical/Surgical Pearls
- Maternal ascertainment of associated anomalies can
prevent early clinical and surgical mishaps,
particularly with regard to spinal defects.
- A multidisciplinary team is critical to the short- and
long-term outcomes in these children.
- A staged surgical repair remains the preferred
approach for most children with cloacal exstrophy.
- Do not underestimate the impact of early gender
assignment. Avoid irreversible surgical resection of
structures that may be useful for genital
reconstruction.
- Save as much bowel as possible, especially the short
hindgut, to maximize nutritional capability.
FERTILITY AND CANCER THERAPY, UROLOGIC CONSIDERATIONS

James M. Hotaling, MD, MS
Craig S. Niederberger, MD, FACS

DESCRIPTION
• 2008 ASCO Guidelines recommend that all patients in their reproductive years undergoing cancer therapy be offered fertility preservation options (1).
• Majority of fertility preservation in men is referral to a reproductive specialist and sperm cryopreservation.
• Sperm cryopreservation is often not covered by insurance but Livestrong Foundation and Fertile Hope offer financial support (2).

EPIDEMIOLOGY
Incidence
• 1.4 million people are diagnosed with cancer every year.
• 10% of those diagnosed with cancer are <44 yr old (3).
• Testicular cancer is one of the most common cancers seen by men in their reproductive years and typically presents to urologists.

Prevalence
Advances in cancer treatment have led to increased survival rates of 75–80% for those diagnosed <50 yr old (4).

RISK FACTORS
Men with male factor infertility (azoospermia) are significantly more likely to develop testis cancer.

GENETICS
• Presence of Vas Deferens
• Longitudinal Testicular Axis
• Sexually Active?
• Nocturnal Emissions?

DIAGNOSIS
• Abnormal Reproductive History
• Gonadotropin Exposure?
• Degree of Consanguinity

BASICS
• For patients with testicular cancer, surgery is typically performed to remove the cancer and preserve fertility.

PHYSICAL EXAM
• Assessment of onset of puberty in adolescent males.
• Discussion of future fertility.
• Discussion of potential fertility preservation options.

DIAGNOSTIC TESTS & INTERPRETATION
• Laboratory evaluation (e.g., FSH, LH, estradiol, total testosterone, sex hormone binding globulin (SHBG), and albumin to calculate bioavailable T).

ASSOCIATED CONDITIONS
• Hematologic malignancies
• Whole-body radiation used before bone marrow transplant usually causes lifelong infertility.

GENERAL PREVENTION
• Radiation to the testes can cause permanent loss of sperm production.
• Unless the cancer is in the testicles, attempt to protect them from radiation by using a shield called a clam shell (5).

GENERAL MEASURES
• Sperm aspiration with cryopreservation of ejaculated sperm by a high-volume lab.

TREATMENT
• Patients should obtain from ejaculation for 2 days before banking sperm but not more than 3 days.
• Fertility preservation should only be done after a frank discussion with the patient regarding the ongoing costs of cryopreservation and methods for patient contact in the future is vital.

HOPE Foundation
• 4.5
• 155 ng/dL
• 15 million
• 39 million/mL
• 10:1
FERTILITY AND CANCER THERAPY, UROLOGIC CONSIDERATIONS

MEDICATION

First Line
• To convert a retrograde ejaculation to an antegrade ejaculation
  – In the United States, ephedrine is most often used
  – In Europe, imipramine is also used
• α-adrenergic agents (dosing highly variable)
  – Pseudoephedrine 60 mg
  – Ephedrine 25–50 mg
  – Imipramine 25–50 mg (may cause dizziness and nausea); commonly used in Europe
  – Frequency ranges from QD to QID
  – Duration ranges from 2 to 14 days
  – Side effects: HTN, tachycardia

Second Line
N/A

SURGERY/OTHER PROCEDURES
In men who are azoospermic, aspiration of seminiferous tubules from the testis, sperm from the epididymis or microTESE with extraction of sperm and cryopreservation is a viable option and should be offered

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PRONOSIS

Roughly 30% of men who receive gonadotoxic chemotherapy or radiotherapy will remain azoospermic permanently

COMPLICATIONS
N/A

FOLLOW-UP
Patient Monitoring
• Men should have a repeat interrogation of their male endocrine axis and another semen analysis by a reproductive health specialist when they desire paternity

• Some men may be hypogonadotropic after completion of treatment and referral to a reproductive health specialist is essential to ensure that they are offered medication other than testosterone for androgen replacement

Patient Resources

• Retrograde Ejaculation
• Semen Analysis, Abnormal Findings, and Terminology
• Semen Analysis, Technique, and Normal Values
• Tanner Stage

CODES

ICD9
• 186.9 Malignant neoplasm of other and unspecified testis
• 606.8 Infertility due to extratesticular causes
• 726.82 Encounter for fertility preservation procedure

ICD10
• C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
• N46.024 Azoospermia due to radiation
• Z31.84 Encounter for fertility preservation procedure

CLINICAL/SURGICAL PEARLS

• < 10% of men who bank sperm retrieve it for use in assisted reproductive technologies.
• Referral to a reproductive specialist and sperm cryopreservation prior to initiation of gonadotoxic chemotherapy, radiation, or radical oncologic surgery is essential
• Cost of sperm cryopreservation typically ranges from $200 to $500 initially usually with an annual maintenance fee.
FILLING DEFECT, UPPER URINARY TRACT (RENAL PELVIS AND URETER)
Scott G. Hubosky, MD

BASES

DESCRIPTION
- Radiographic diagnosis of a radiolucent entity occupying the confines of the upper urinary tract including the intrarenal collecting system or ureter, as seen against contrast within the intraluminal space.
- The finding itself is non-specific but may represent malignant or benign processes.
- Histoscopic evaluation is the gold standard to establish definitive diagnosis.

PHYSIOLOGY
N/A

GENETICS
N/A

RISK FACTORS
- For UTUC:
  - History of smoking
  - History of urothelial carcinoma of the bladder
  - Gene carrier or family history of Lynch syndrome (hereditary nonpolyposis colorectal cancer)
  - Previous stone history
  - Chronic dehydration
  - Elevated sodium intake
  - Purine gluttony
  - For sloughed papilla:
    - MSAD disease
    - Sickle cell disease or trait
  - History of diabetes
  - For fungus ball:
    - Immunosuppression

DIAGNOSIS

HISTORY
- Flank pain or renal colic
- Hematuria
- Gross
  - Microscopic
  - Pre-existing malignancy
  - History or urinary diversion
  - Prior urinary tract manipulation (scent, stone treatment, etc.)
  - Intraluminal administration of contrast
  - Retrograde pyelogram
  - Antegrade nephrostogram
  - IVP
  - Intravenous injection of contrast
  - Intravenous urogram
  - CT urogram
  - MR urogram
  - Cystogram (if reflux present)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine culture including fungal cultures
- Serum creatinine/BUN
- Urine cytology may suggest malignancy
- Sediment analysis

Imaging
- Filling defects are found in imaging modalities which utilize contrast that fills the intrarenal collecting system
  - Intravenous urography
  - Secretory urogram
  - Intravenous injection of contrast
  - Retrograde pyelogram
  - Antegrade nephrostogram
  - Cystogram (if reflux present)
  - CT urogram
  - MR urogram
  - IVP
  - Intravenous injection of contrast

Pathologic Findings
Depends on underlying etiology

DIFFERENTIAL DIAGNOSIS
- Malignant lesions
  - UTUC
  - Rare primary cancers of the upper urinary tract
  - Squamous cell carcinoma (often associated with chronic untreated infected staghorn calculi)
  - Adenocarcinoma
  - Inverted papilloma (about 15% have malignant components)
  - Sarcoma
  - Leiomyosarcoma
  - Adenocarcinoma
  - Small cell carcinoma
  - Metastatic carcinoma
  - Renal cell carcinoma
  - Benign lesions
    - Ac: iatrogenic, infectious, fistula
    - Blood blister
    - Fibroepithelial polyp
    - Fungus ball
    - Hemangioma
    - Inflammatory lesions: Granuloma, malakoplakia, TB
    - Sloughed papilla
    - Calsies (usually radiolucent)
    - Malignant lesions: Leukemia, lymphoma, cholesterol, dystrophic compression of the ureter
    - Mucous (malignancy) or diverticula
    - Protein matrix
    - Urothelial or papillary cystica
    - Vascular impression
    - Fibroepithelial polyp
    - Papilla
    - Prominent papilla (ectopic or end on; normal anatomic variant)
    - Sloughed papilla (may cause obstruction or hematuria)
    - Foreign body
    - Stent fragment (retained)
    - Staple/clip (more likely with urinary diversion)

TREATMENT

GENERAL MEASURES
- If any doubt exists about the etiology of the filling defect then diagnostic uroscopy is indicated.
- Benign tumors may appear as filling defects, in the very peripheral aspect of renal calyces in an “end on” position.

MEDICATION
First Line
- For stones composed purely of uric acid manifesting as filling defects, alkalinization of the urine can be attempted and if pH of 6.5 or greater is achieved then uric acids may dissolve over time.
- Potassium citrate
- Sodium bicarbonate

Second Line
N/A
SURGERY/OTHER PROCEDURES

- **UTUC**
  - For low-grade UTUC which can be reached endoscopically and completely ablated, 5-yr survival is equal to radical nephroureterectomy (RNU).
  - After complete ablation, local recurrence can be seen in up to 75% of patients. If followed for at least 5 yr.
  - Progressive of low-grade to high-grade disease occurs in about 15% of cases.
  - These points should be stressed to patients when counseling on the management of UTUC.
  - For high-grade UTUC or very large volume low-grade UTUC, radical exstirpative surgery is considered the gold standard for cancer control.

- **Nephrolithiasis**
  - Ureteroscopy with laser lithotripsy.
  - Cross-sectional imaging (CT or MRI) is recommended to check for locally advancing disease.

- **Fibroepithelial polyp**
  - Can be removed with ureteroscopy using laser or grasper.
  - Avoid overuse of NSAIDs.

- **Sloughed papilla**
  - Can be removed with ureteroscopy using laser or grasper.

- **Ureteral grasper**
  - Cross-sectional imaging are also needed on a regular basis (NU), surveillance cystoscopy and cross-sectional imaging are also needed on a regular basis.

- **Antireflux surgery**

ADDITIONAL TREATMENT

- **Radiation Therapy**

Additional Therapies

- **UTUC**
  - Neoadjuvant chemotherapy is currently under investigation for suspected high-stage disease with preliminary data suggesting down-staging on pathologic specimens.

- **Complementary & Alternative Therapies**

ONGOING CARE

PROGNOSIS

- Depends on underlying etiology.

- Prognosis usually excellent for benign conditions.

- UTUC (prognosis depends on pathologic staging (pT)). TNM pathologic staging and prognosis is as follows:
  - pT0, pTa, and pTis have 95% and 89% cancer-specific survival at 5 and 10 yr.
  - pT1 has 91% and 89% cancer-specific survival at 5 and 10 yr.
  - pT2 has 75% and 70% cancer-specific survival at 5 and 10 yr.
  - pT3 has 54% and 45% cancer-specific survival at 5 and 10 yr.
  - pT4 has 12% and 6% cancer-specific survival at 5 and 10 yr.

COMPLICATIONS

NA.

FOLLOW-UP

Patient Monitoring

- **Ureteroscopy**

  - For those undergoing ureteroscopic conservative treatment, regular surveillance including cystoscopy and ureteroscopy is required given high chance of local recurrence.

  - Cross-sectional imaging (CT or MRI) is recommended to check for locally advancing disease.

  - For those undergoing radical nephroureterectomy (RNU), surveillance cystoscopy and cross-sectional imaging are also needed on a regular basis.

- **Nephrolithiasis**

- **Filling Defect, Upper Urinary Tract (Renal Pelvis and Ureter)**

- **Fibroepithelial Polyp, Genitourinary**

- **Ureter and Renal Pelvic Tumors, General**

- **Ureter and Renal Pelvic Tumors, Nephromas**

- **Antireflux surgery**

ADDITIONAL READING

- **Ureter and Renal Pelvis, Squamous Cell Carcinoma**

- **Ureter and Renal Pelvis, Urothelial Carcinoma**

- **Urolithiasis, General**

- **ICD9**

  - 189.1 Malignant neoplasm of renal pelvis.

  - 189.2 Malignant neoplasm of ureter.

- **ICD10**

  - C66.9 Malignant neoplasm of unspecified ureter.

  - C66.9 Malignant neoplasm of unspecified ureter.

- **ICD10-PCS**

  - B81.4 Abdominal findings on diagnostic imaging of urinary organs.

- **CLINICAL/SURGICAL PEARLS**

  - Up to 40% of patients with an upper tract urothelial carcinoma will develop urothelial carcinoma of the bladder.

  - Ureteroscopy can be both diagnostic and therapeutic.
FLANK PAIN, GENERAL

Taylor B. Vaughan, MD
James S. Rosoff, MD

DIAGNOSIS

HISTORY
- Age and sex of patient
- Past medical history
  - Congenital anomalies
  - Urologic disease
  - Prior surgery
  - Infections
- Familial and genetic history
- Personal history
  - Tobacco use
  - Alcohol use
  - Maternal history
- Medications
- Psychosocial factors
- Use of herbal medications
- Genetic testing

PHYSICAL EXAM
- Vital signs
  - Temperature
  - Heart rate
  - Respiratory rate
  - Blood pressure
- General appearance
  - Skin and orifices
  - Neurologic examination
- Localized findings
  - Flank pain
- Associated symptoms
  - Nausea, vomiting
  - Hematuria
- Radiation
  - Radiation to lower extremities
  - Radiation to back

DIAGNOSTIC TESTS & INTERPRETATION

Lab tests
- Complete blood count
  - White blood cell count
  - Hemoglobin
  - Hematocrit
- Liver function tests
- Creatinine
- Urea nitrogen
- Electrolytes
- Urinalysis

Radiology
- Ultrasound
- CT scan
- MRI
- Excretory urogram/IVP

BASICS

DESCRIPTION
- Flank pain refers to pain or discomfort in the side of the abdomen between the last rib and the hip.
- Sometimes referred to as loin pain, it is often associated with urologic conditions, although not exclusively.

EPIDEMIOLOGY

Incidence
- True incidence is difficult to ascertain, as it is a common symptom associated with many medical conditions.

Prevalence
- Many medical conditions can cause flank pain, the prevalence is high.
- Up to 12% of the adult US population will suffer from urinalithiasis at some point.

RISK FACTORS
- Risk factors are dependent upon etiology

GENETICS
- Flank pain caused by urolithiasis is usually due to a history of a familial or congenital disorder.
- Flank pain from renal inflammation may be due to a history of trauma or infection.

PATHOPHYSIOLOGY
- Flank pain from renal causes may be due to obstruction, infection, or renal cell carcinoma.
- Flank pain from chronic obstruction is generally less severe, or may be absent.

ASSOCIATED CONDITIONS
- Pregnancy Considerations:
  - Pregnancy alone may cause flank pain in up to 20% of women (more commonly on the right side).
- Flank pain may occur as a symptom of many medical conditions.

GENERAL PREVENTION
- Strategies for the prevention of urolithiasis or nephrolithiasis depend on the underlying metabolic abnormality.
- Diet modifications may be necessary depending on the underlying metabolic abnormality.
- Calcium reduction has not been shown to affect the likelihood of recurrent stone formation in most patients.
DIFFERENTIAL DIAGNOSIS

Pathologic Findings

There are many causes of flank pain. It is useful to differentiate between urologic and nonurologic causes. Renal/ureteral etiologies are the most common and those that usually require urologic intervention. Some of the most common causes are listed below (3):

• Urologic
  - Calculi: Mostly renal, however, renal pelvic and calyceal stones (obstructing infundibulum) can cause flank pain
  - Acute pyelonephritis
  - Acute papillary necrosis
  - Prune belly syndrome
  - Polycystic kidney disease
  - Acute tubular necrosis
  - Renal infarction (renal artery thrombus or dissection)
  - Renal cyst (especially hemorrhagic; benign cysts rarely cause flank pain)
  - Renal neoplasm
  - Renal trauma
  - Renal vein thrombosis
  - Retroperitoneal bleed or mass
  - Ureteropelvic junction obstruction
  - Cystic renal disease
  - Medullary sponge kidney
  - Other urothelial obstruction (extrinsic compression, blood clot, necrotic material, etc.)
  - Neoplastic:
    - Appendicitis
    - Abdominal aortic aneurysm
    - Diabetes
    - Diverticulitis
    - Hespos zoster
    - Macrocystic renal (muscle-sparing, costochondritis, strain)
    - Myocardial infarction
    - Diabetic torsion
    - Pancreatitis
    - Peripheral nerve compression or trauma
    - Peripheral neuropathy
    - Mumps
    - Tubal pregnancy
    - Ventral or spinal cord/neural entrapment
    - Perineal disc, sciatica, ventral body fracture, or colliqua

MEDIATION

First Line

• Acute pain control (NSAIDs, opioids)
• Anxiolitics, antispasitics, antibiotics as appropriate
• IV fluids if sepsis/hypovolemia. May also help with passage of stones

Second Line

• Anticoagulation and calcium channel blockers may help with expulsion of urinary stones

SURGERY/OTHER PROCEDURES

• Prior to any diagnostics or intervention, the patient must be stabilized.
• Surgical management may be required in some cases depending on the etiology and the patient’s medical condition.
• Examples of surgical management: If the collecting system is infected and obstructed or renal abscess is present, percutaneous drainage and antibiotics are the mainstays of treatment. If dealing with a ruptured AML, embolization should be considered. Ruptured tumor should be treated on an elective basis. Emergent nephrectomy for ruptured AML, or XGP/emphysematous pyelonephritis may be necessary.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Complementary & Alternative Therapies

N/A

ONGOING CARE

Follow-up for flank pain will also be dictated by the etiology and acuity of the clinical presentation. Repeat imaging or other lab studies may be required depending on response to initial therapy.

If clinical picture fails to improve or worsens, a change in therapy should be instituted (ie, different antibiotic, PCN, surgical intervention).

PROGNOSIS

In general, for nephrolithiasis, the prognosis is good but this may vary for other etiologies.

COMPLICATIONS

Longstanding ureteral obstruction can cause permanent loss of renal function.

FOLLOW-UP

Patient Monitoring

Periodic renal imaging, urinalysis, or 24-hr urine may be indicated for patients with stone disease. Follow-up may be more or less intensive based on etiology.

Patient Resources

See Also (Topic, Algorithm, Media)

• Calculifications, Abdominal and Pelvic
• Hydropnephrosis/Hydronephrosis (Dilated Ureters/Renal Pelvis)

CODES

ICD-10

• N23.9 Urinary calculus, unspecified
• 788.0 Renal colic
• 995.9-6 Abdominal pain, other specified site

ICD-19

• N23.9 Urinary calculus, unspecified
• N23 Unspecified renal colic
• R10.9 Urinary tract infection, unspecified

CLINICAL/SURGICAL PEARS

• Flank pain associated with fever and chills may represent urinary tract infection (pyelonephritis).
• Abdominal aortic aneurysm is a potentially life-threatening cause of flank pain.
**Foley Catheter Problems (Insertion and Removal)**

James Kearns, MD

### BASICS

**DESCRIPTION**
- The terms “urethral catheter” and “Foley catheter” are often used interchangeably. Urethral catheter is a general description of a tube that traverses the urethra whereas a Foley catheter refers to a urethral catheter with a retention balloon.

**Common types of urethral catheter include:**
- Foley: rounded tip with balloon
- Coudé: angulated distal tip to allow for navigating past large prostates or elevated bladder necks

- 2-way catheters have a drainage port and a balloon port.
- 3-way catheters have a drainage port, an infusion port, and a balloon port.

- Note: Drainage channel is larger in a 2-way catheter than 3-way catheter of the same size.

- Size measured in Charrière or French (Fr) scale
  - Fr = 3.5 × 10−3 mm
-Common sizes include 5–10 Fr in the pediatric population and 16–24 Fr in the adult population
-Common materials include latex and silicone
- Silicone is better for long-term or latex allergy
- Hydrophilic coatings may facilitate easier passage of catheter
- Problems can occur with insertion, drainage, or removal

### EPIDEMOLOGY

**Incidence**
- Unknown but very common in hospitalized patients

**Prevalence**
- N/A

### RISK FACTORS

- Hospitalized patients requiring strict documentation of urine output
- Bladder neck contracture, previous urethral or prostate surgery
- Trauma, immobility, obesity

**Genetics**
- N/A

### PATHOPHYSIOLOGY

Indications for urethral catheterization include need for bladder decompression, need for accurate monitoring of urine output, immobility during postoperative setting, diversion of urine from wounds, instillation of therapeutic agents, and facilitation of certain diagnostic studies (eg, urodynamics, VCGUS, cystogram)

### ASSOCIATED CONDITIONS

- BPH
- Balanitis xerotica obliterans (BXO)
- UTI
- Urinary retention
- Neoplastic bladder
- Liver failure, heart failure—edema

### GENERAL PREVENTION
- Minimization of unnecessary urethral catheterization
- Removal of urethral catheter as soon as clinically indicated
- Proper insertion technique prevents false passages and potential bladder neck or urethral strictures
- Catheter should always be placed without undue force, using copious lubrication
- Excess force may lead to false passage creation

### ALERT

- Do not inflate Foley balloon unless the catheter is confirmed in the bladder.
- Look for urine return and insert catheter until “hub” reaches urethral meatus.
- If no urine return with “hubbled” catheter, irrigate normal saline into the bladder with a catheter-tipped syringe; 120 mL is often necessary before fluid can be aspirated.
- Inflation in urethra or prostate may lead to significant hematuria or future urethral stricture as well as inability to place another catheter.
- Always inflate balloon with water as saline may crystallize and is usually not necessary to test balloon prior to insertion

### DIAGNOSIS

**HISTORY**
- Previous difficulty with catheterization
- Urethral instrumentation in the past
- Episodes of urethral catheterization
- Prior pelvic radiation or biotherapy
- History of urinary symptoms
  - Quality of urinary stream, urinary frequency, sensation of emptying, history of urinary retention
- Circumcision may lead to meatal stenosis

**PHYSICAL EXAM**
- Abdominal examination for palpable bladder, dullness to percussion over lower abdomen
- DRE feels for evidence of prostate cancer (nodularity or hardness), prostatic abscess (tender prostate), urethral disruption (high-riding or nonpalpable prostate)
- Bimanual examination to evaluate for bladder or pelvic masses
- Palpate penis for strictures
  - Both location and length of stricture important
- Blood at meatus suggests trauma/urethral disruption

### DIAGNOSTIC TESTS & INTERPRETATION

**Lab**
- Electrolytes and creatinine to evaluate for renal function
- Decreased renal function in an obstructed patient is risk factor for postobstructive diuresis

**Imaging**
- Generally unnecessary
- Retrograde urography can demonstrate urethral disruption, hydronephrosis, or stricture
- Cystourethroscopy, if needed

**Diagnostic Procedures/Surgery**
- Catheterization is both diagnostic and therapeutic
  - See treatment section

**Pathologic Findings**
- If performed in OR, may consider biopsy of strictures

### DIFFERENTIAL DIAGNOSIS

**General Measures**
- Assess need for urethral catheterization
- For difficult placement, start with an 16–18 Fr Foley and note location of difficulty
- If stricture suspected, attempt 1 pass with 12–16 Fr Foley
- If BPH suspected, attempt 1 pass with 18–22 Fr coudé
- Choose proper catheter size for pediatric population
- Newborns/neonates based on body weight (no retention balloon)
  - < 1000 gm: 3.5 Fr
  - 1000–1800 gm: 5 Fr
  - 1800–4000 gm: 6.5 Fr
  - ≥ 4000 gm: 8 Fr
- Children
  - Age 0–5 yr, 5–8 Fr
  - Age 5–10 yr, 8–10 Fr
  - Age 10–14 yr, 10 Fr
- Age > 14 yr, 12–14 Fr

### MEDICATION

**First Line**
- Intravesical lidocaine jelly may be useful in difficult catheter placement
**Second Line**
- Hyoscine

### SURGERY/OTHER PROCEDURES

**Urethral sphincter spasm**
- Provide reassurance and ask patient to relax and take slow, deep breaths
- Intravesical lidocaine jelly may not decrease pain (1)
- Instruct patient to attempt to void when encountering the sphincter
**BPH**
- Use a coudé catheter to help navigate the prostate
- Bend of catheter always facing up toward ceiling (often matches a raised area on balloon port)
- Larger (ie, 20–22 Fr) preferable because less likely to bend on itself
**FOLEY CATHETER PROBLEMS (INSERTION AND REMOVAL)**

- Urethral stricture/bladder neck contracture  
  - If unable to pass 14 Fr or larger catheter, dilation likely necessary  
  - General principle is to place catheter over a wire into the bladder using feeding technique  
  - Flexible cystoscopy is ideal  
  - Advance scope to level of stricture  
  - Pass 0.038” wire through stricture into bladder  
  - If cystoscope unavailable, consider filtration with followers, or blindly pass 0.038” soft-tip wire into bladder and confirm location of wire in bladder  
  - Portable pelvic x-ray  
  - Insert 5-F open-ended catheter over wire and aspirate; presence of urine indicates bladder location of wire

**ALERT**

Never dilate urethra unless wire in bladder.  
- Wire rigid enough to potentially undermine bladder neck or enter rectum:  
  - Dilate over wire using serial Amplatz-type renal dilators to 1 size larger than desired catheter (ie, 23 Fr for 20-Fr catheter)

- If dilators unavailable, serial silicone catheters may be rigid enough for dilation:  
  - Insert Council catheter over wire until return of urine and inflow balloon

- If Council unavailable, use 14-gauge Angiocath to thread wire into Foley.

- Urethral disruption  
  - Retrograde urethrogram generally necessary for diagnosis, but consider blind passage of catheter in trauma patient without pelvic fracture or signs of urethral injury (ie, blood at meatus, perineal hematoma, high-riding prostate) (2)  
  - Consider cystoscopically inserting catheter  
  - Use trocar for suprapubic catheter

- Urethral false passage  
  - False passage generally down, so use coude with tip pointed up  
  - If unable to pass coude, use cystoscope to place wire in bladder and place catheter over wire

- Phimosis  
  - Attempt to retract foreskin  
  - If able to visualize meatus, attempt to place Foley through meatus normally  
  - If unable to visualize meatus, perform dorsal slit in foreskin under local anesthesia  
  - Manual stenosis  
    - Inject lidocaine gel  
    - Serial dilations with Van Buren sounds  
    - Penile balanitis edema

- Manually compress edematous skin to minimize edema  
  - Place catheter once meatus visible

- Retracted female meatus  
  - Inserting a finger into the vagina may bring meatus forward

- Manually retract catheter into meatus

- Urethral stone or foreign body  
  - Cystoscopically remove stone/foreign body

- Clot retention with no catheter output  
  - Ensure at least 20-Fr 2-way catheter

- Manually irrigate catheter  
  - If urine does not remain clear after irrigation, consider placing 3-way catheter (02 or 24Fr) for continuous irrigation

**ALERT**

If catheter from catheter stops while on continuous bladder irrigation (CBI), immediately stop inflow.  
- Decreased catheter output from bladder debris:  
  - Manually irrigate

- Consider insertion of larger catheter  

- Inability to remove catheter:  
  - Place syringe on balloon port for 30 min

- Cut balloon port and wait for fluid output

- Insert stiff end of wire through balloon port to attempt to undo the port

- If still unable to remove catheter:  
  - Under US guidance, spinal needle may be inserted into balloon percutaneously

- In women, transvaginal US and needle placement may be preferable  
  - If balloon palpable in bulbar or pendulous urethra, transcervical placement of a22-gauge needle may decompress balloon  
  - If catheter situated in place and suture resorbable, consider waiting before removing catheter

- Open cystotomy with urethral removal is a final resort

**ADDITIONAL TREATMENT**

Radiation Therapy

Additional Therapies

- May be necessary for suprapubic catheterization

**Compilimentary & Alternative Therapies**

**ONGOING CARE**

**PROGNOSIS**

**COMPLICATIONS**

- False passage  
  - Hematuria  
  - Catheter-associated UTI  
  - Many catheters have antimicrobial coatings, which may not be beneficial (3)

**FOLLOW-UP**

Patient Monitoring  

- Before removing difficult Foley, ensure no febrile indication for reinsertion of catheter

- Consider removing catheters at midnight so a failed voiding trial can be managed early during the day

**Patient Resources**

**REFERENCES**

See Also (Topic, Algorithm, Media)

- Benign Prostatic Hyperplasia
  - Foley Catheter Problems (Insertion and Removal)

- Flexible cystoscopy is ideal

- General principle is to place catheter over a wire

- If unable to pass 14 Fr or larger catheter, dilation likely necessary

- Always confirm wire in bladder before dilating.

- Perform voiding trials at times that allow for reinsertion of difficult catheter at a convenient time.

- Suprapubic catheterization is a reliable method of bladder drainage, if needed.

- Remove catheter as soon as possible to reduce risk of catheter-associated UTI.

**ICD9**

- 996.64 Infection and inflammatory reaction due to indwelling urinary catheter

- 996.76 Other complications due to genitourinary device, implant, and graft

- 953.6 Fitting and adjustment of urinary device

**ICD10**

- T83.89XA Other specified complication of genitourinary prosthetic devices, implants and grafts, initial encounter

FOURNIER GANGRENE
Brad Figler, MD
Bryan Voelzke, MD, MS

DESCRIPTION
FOURNIER GANGRENE is a urologic emergency, causing progressive tissue destruction with significant potential for soft tissue loss, septic shock, and death. Prompt debridement is mandatory.

RISK FACTORS
- Diabetes mellitus
- Genital skin trauma
- Impaired immunity
- Recent penile, perineal, or perirectal surgery
- IV drug abuse
- Male
- Most common in 5th and 6th decades of life
- Rates of spread as high as 2–3 cm/h have been reported
- Obliterative endarteritis leads to thrombosis, ischemia, and necrosis, which allows for further bacterial proliferation
- Pathogen differs from nonnecrotizing infection: Higher frequency of virulent organisms such as group A streptococcus, community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA), and Clostridium spp
- Testicular torsion
- Vasculitis
- Epididymitis/epididymitis
- Intraabdominal sepsis
- Pyoderma gangrenosum
- Strangulated inguinal hernia
- Testicular torsion

ASSOCIATED CONDITIONS
- Perianal/perineal abscess
- Immunosuppression
- Obesity
- Urethral structure
- Paraplegia
- Malignancy
- Septic abortions, vulvar abscesses, and epistaxis (in women)

DIAGNOSIS
HISTORY
- Presentation is typically abrupt with severe pain in the perineum, abdominal wall and thighs, however a prodrome of several days of fever and lethargy can be seen
- Perineal or genital trauma (including bites)
- Urethral instrumentation
- Perianal/perineal abscess or wound
- Urinary tract infection or STD
- Urethral stricture disease
- Anal fissure, fistulae, or hemorrhoids
- Alcohol or IV drug abuse
- Malnourishment
- Diabetes mellitus
- Steroid use
- HIV

PHYSICAL EXAM
- Pain out of proportion with physical exam
- Tachycardia and tachypnea
- Fever or hypothermia
- Altered mental status
- Pain out of proportion with physical exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Lymphopenia/thrombocytopenia, anemia
- Serum chemistry: Metabolic acidosis
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

Pathologic Findings
- Infection presumed present as far peripherally as dermis
- Incision should be extended until normal appearing tissue is encountered
- Coagulopathy
- Glucosuria and pyuria
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained
- Septic abortions, vulvar abscesses, and epistaxis (in women)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Lymphopenia/thrombocytopenia, anemia
- Serum chemistry: Metabolic acidosis
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

Pathologic Findings
- Infection presumed present as far peripherally as dermis
- Incision should be extended until normal appearing tissue is encountered
- Coagulopathy
- Glucosuria and pyuria
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

PATHOPHYSIOLOGY
- Primary insult is a breach in the integrity of the GI or urethral mucosal lining
- Infection is frequently polymicrobial (aerobic and anaerobic, gram-positive and gram-negative)
- Pathogen differs from nonnecrotizing infection: Higher frequency of virulent organisms such as group A streptococcus, community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA), and Clostridium spp
- Obliterative endarteritis leads to thrombosis, ischemia, and necrosis, which allows for further bacterial proliferation
- Process extends along Dartos and Colles fascia, potentially involving perineum, abdomen, thighs, ischiosciatic fossa, and retroperitoneum
- Rates of spread as high as 2–3 cm/h have been reported
- Deep structure (corpus cavernosum, corpus spongiosum, and testicles) are typically not affected

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Lymphopenia/thrombocytopenia, anemia
- Serum chemistry: Metabolic acidosis
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

Pathologic Findings
- Infection presumed present as far peripherally as dermis
- Incision should be extended until normal appearing tissue is encountered
- Coagulopathy
- Glucosuria and pyuria
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Lymphopenia/thrombocytopenia, anemia
- Serum chemistry: Metabolic acidosis
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

Pathologic Findings
- Infection presumed present as far peripherally as dermis
- Incision should be extended until normal appearing tissue is encountered
- Coagulopathy
- Glucosuria and pyuria
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Lymphopenia/thrombocytopenia, anemia
- Serum chemistry: Metabolic acidosis
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained

Pathologic Findings
- Infection presumed present as far peripherally as dermis
- Incision should be extended until normal appearing tissue is encountered
- Coagulopathy
- Glucosuria and pyuria
- Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
- Deep tissue cultures at the time of surgery should be obtained
TREATMENT

GENERAL MEASURES
• Immediate and aggressive surgical therapy with debridement of necrotic tissue
• Aggressive fluid resuscitation (isotonic fluid)
• Intotopic support is frequently necessary
• Correct hypernatremia
• Quadruple antibiotics
• ICU support until clinically stable

MEDEICATION
First Line
• Antibiotics should include gram-positive, gram-negative, and anaerobic coverage in full therapeutic doses
• Modify antibiotics as needed, based on Gram stain, culture, and sensitivity
• Appropriate empiric therapy typically consists of:
  – Piperacillin/tazobactam
  – Ertapenem
  – Imipenem/cilastatin
  – Vancomycin 1 g IV BID (MRSA)
  – Clindamycin 600–1,200 mg/d, divided dose
  – Penicillin G 3–5 million international units IV q6h
  – Nutritional support (preferably enteral) should be instituted early to correct the negative nitrogen balance associated with profound sepsis

ADDITIONAL TREATMENT
• VAC may result in earlier wound granulation compared to simple wet-to-dry dressing changes, but may be difficult to apply to the perineum and genitalia
• A VAC should be placed with fine-mesh gauge sealed in normal saline
• Don’t perform cystoscopy if there is concern for urethral involvement
• Don’t perform cystoscopy if there is concern for urethral involvement
• Aggressive fluid resuscitation (isotonic fluid)
• Immediate and aggressive surgical therapy with proctoscopy under anesthesia is necessary extensivly involved

ONGOING CARE

PROGNOSIS
• Historically, fournier gangrene carried a >50% mortality rate
• Modern mortality rates average 5–20%, which is highly dependent on prompt diagnosis and right coordination of definitive care

COMPLICATIONS
• Coagulopathy
• Death from sepsis
• Disfiguring skin and soft tissue loss
• Infertility
• Multi system organ failure
• Renal failure
• Urinary incontinence

FOURNIER GANGRENE

ADDITIONAL READING
2. See Also (Topic, Algorithm, Media)
• Diabetes Mellitus, Urologic Considerations
• Unexpanded (Septic) Wound
• Fournier Gangrene Images

CODES
ICD9-10
• 616.89 Other inflammatory disease of cervix, vagina and vulva

CLINICAL/SURGICAL
PEARLS
• Signs of local infection with pain out of proportion to physical exam is highly suspicious for a diagnosis of fournier gangrene.
• Prompt and radical debridement is mandatory.
• Infections are typically polymicrobial, so broad-spectrum antibiotics are critical.

FOLLOW-UP
Patient Monitoring
Prolonged critical care may be required.

FUNGAL INFECTIONS, GENITOURINARY

Michael A. Pontari, MD
Daniel C. Parker, MD

DESCRIPTION
Primary fungal infection of the genitourinary (GU) tract is common with Candida, but uncommon with other fungi.

Other fungal infections are found in the GU tract but are seen more commonly with immunocompromised patients or in setting of systemic disease.

EPIDEMIOLOGY
Incidence
- Difficult to determine because most cases are not reportable
- Estimated 1–2 new cases per 100,000 population per year involving the GU tract

Prevalence
- Difficult to estimate as cases are not reportable

RISK FACTORS
- Urinary tract drainage catheter
- Prior antibiotics
- Diabetes mellitus
- Uranuria
- Female sex
- Prior surgical procedures
- Immunocompromise

Genetics
- No heritable form of transmission

PATHOPHYSIOLOGY
- Funguria to funguria:
  - Can occur with obstruction, reflux, or instrumentation
- Fungi to funguria:
  - Disseminated disease seeds GU tract
  - Multiple microabscesses develop in the renal proximal tubules

ASSOCIATED CONDITIONS
- Immunocompromised state
  - Diabetes
  - AIDS
- Anatomic GU abnormalities
  - Strictures
  - Prostatic hypertrophy
  - Diverticula
  - Indwelling tubes
  - Stones

GENERAL PREVENTION
- Remove unnecessary catheters/tubes
- Narrow antibiotic coverage
- Improve nutritional status
- Control hyperglycemia

DIAGNOSIS
HISTORY
- Immunocompromised state:
  - Fungi are ubiquitous in the environment and can overwhelm those with weakened immune systems
- Those receiving chemotherapy, with AIDS, or affected with diabetes
- Recent antibiotic use:
  - Risk of candiduria is 6–10× after use of broad-spectrum antibiotics
- Indwelling GU tubes or prosthesis:
  - Risk of Candida 12× with catheterization
- GU tract abnormalities:
  - Risk of candiduria 6–10× with abnormalities (TIA)

- Occupation:
  - Exposure to aerosolized soil; spelunkers; bird handler
- Recent travel or recreation (see image):
  - Blastomycosis found in Ohio, Missouri, and Mississippi river basins; Great lakes, Canada
  - Coccidioidomycosis found in semiarid regions of the Western US, Mexico, Central and South America
  - Histoplasmosis found in Midwestern and Southern US in areas of high-nitrogen soil such as chicken coops and bat caves

- Immunocompromised state:
  - Risk of candiduria is 6–10× after use of broad-spectrum antibiotics

- Prior antibiotics:
  - Risk of candiduria is 12× after use of broad-spectrum antibiotics

- Recent antibiotic use:
  - Risk of candiduria in (3)[A]:
    - Asymptomatic patients
      - Urine culture
      - Symptomatic patients
      - Urine culture
      - Urine culture
      - Neutropenic patients
      - Patients who will have GU procedures
      - Infants with low birth weight

- Infectious Diseases Society of America recommends treatment of candiduria in (3)[A]:
  - Clotrimazole, miconazole, terconazole topical for 1 wk
  - Fluconazole 200 mg/d for 1–2 wk
  - Amphotericin B 1–1.5 mg/kg/d for 10 wk

- Blood clots in collecting system
- Cryptococcus
- GU TB
- Neutropenias
- Squamous cell carcinoma (SCC)
- Urothelial carcinoma (transitional cell carcinoma)

TREATMENT
GENERAL MEASURES
- Infected Diseases Society of America recommends treatment of candiduria in (3)[A]:
  - Infants with low birth weight
  - Patients who will have GU procedures
  - Neutropenic patients
  - Symptomatic patients
- Treat UTI symptoms empirically for funguria only if the patient is unable to vocalize or perceive symptoms
- Asymptomatic candiduria: Asins for risk factors (3)[A]

MEDICATION
First Line
- Aspergillosis:
  - Amphotericin B 1.5–3 mg/kg/day for 10 wk
- Blastomycosis:
  - Itraconazole 200 mg PO BID for 4–6–12 mo
- Candidiasis:
  - Clotrimazole, miconazole, terconazole, econazole topical for 1 wk
- Candidiasis:
  - Fluconazole 100 mg PO for 1–2 wk

SECOND LINE
- Aspergillosis:
  - Amphotericin B 1–1.5 mg/kg/day for 10 wk
- Blastomycosis:
  - Itraconazole 200 mg PO BID for 1 year
- Candidiasis:
  - Fluconazole 200 mg PO BID for 4–6–12 mo
- Cryptococcus:
  - Amphotericin B 0.5 mg/kg/day for 1 year
- Fusarium:
  - Fluconazole 100 mg PO BID for 1 year

DIFFERENTIAL DIAGNOSIS
- Blood clots in collecting system
- Cryptococcus
- GU TB
- Neutropenias
- Squamous cell carcinoma (SCC)
- Urothelial carcinoma (transitional cell carcinoma)
FUNGAL INFECTIONS, GENITOURINARY

ADDITIONAL TREATMENT

Radiation Therapy
None

Additional Therapies
• Irrigation may be necessary in infectious infections when systemic medication is not excreted into the urine.
  • Amphotericin B GU tract irrigation
    – 50 mg in 1,000 mL water at 40 mL/hr
    (over 24 hr) for 5–7 days
  • In children, renal irritation with 10–24 mg/dl
  • Removing catheter may eradicate funguria in 40% of cases

Complementary & Alternative Therapies
None

ONGOING CARE

PROGNOSIS
• Candiduria does not predict development of candidiasis in most people
  • Rates 1.3–10.5%
• No different in renal transplant population: 5%
• Aspergillosis mortality 40–90% with treatment
• Pyococcosis (necrotizing, hypernephric) mortality 90% if untreated, 24% with nephrectomy and amphotericin B

COMPICATIONS
• Renal failure
• Empyemathous pyelonephritis
• Obstruction, pyonephrosis, death
• Fibrillary necrosis
• Perinephric abscess
• Renal scarring

FOLLOW-UP

Patient Monitoring
• Surveillance cultures can be obtained to document clearance of infection.
• Fungal urine can be fungal reservoir for recurrent infection.

Patient Resources

CODES

ICD9
• 116.1 Candidiasis of vulva and vagina
• 116.2 Candidiasis of other urogenital sites
• 116.0 Blastomycosis

ICD10
• B37.1 Candidiasis of vulva and vagina
• B37.4 Candidiasis of other urogenital sites
• B40.89 Other forms of blastomycosis

CLINICAL/SURGICAL PEARLS

• When fungal infections are found in the GU tract in patients without risk factors, a search for systemic disease is warranted.
• Disseminated fungal disease can seed the GU tract through the development of renal microabscesses.
• Fungal infections are encountered in various geographic locales based on type.
• Treat candiduria in infants with low birth weight, those undergoing GU procedures, neutropenic patients, and symptomatic patients.
• Surgical drainage of fungal infections is indicated in cases of urinary tract obstruction.

• Cryptococcosis:
  • Amphotericin 0.5–1 mg/kg/d IV + fluconazole 100 mg/kg/d PO for 2 wk
  • Then fluconazole 400 mg PO for 8 wk OR
  • Then itraconazole 200 mg PO BID for 8 wk
• For oropharyngeal suppression:
  • Fluconazole 200 mg PO OR
  • Amphotericin 0.5–1 mg/kg IV every week
• Histoplasmosis:
  • Itraconazole 200 mg PO BID for 6–18 mo
  • For histoplasmosis suppression:
    • Itraconazole 200 mg PO BID OR
    • Amphotericin 0.5–1 mg/kg IV every week
• Mucormycosis:
  • Amphotericin 8–1.5 mg/kg IV for 6–10 wk

Second Line
• Aspergillosis:
  • Voriconazole 6 mg/kg q12h for 2 days, then 4 mg/kg q12h IV or oral for 10 wk OR
  • Itraconazole 200 mg PO BID for 4 days, then 200 mg PO q12h for 12 days, then 200 mg PO BID for 10 wk OR
  • Itraconazole 200 mg PO TID for 9 days, then 200 mg PO BID for 10 wk
• Blastomycosis:
  • Amphotericin 0.5–1 mg/kg for 6–12 wk OR
  • Fluconazole 400–800 mg PO for 6–12 mo
• Candidiasis:
  • Fluconazole 150 mg q12h
  • Candida (until 2 wk after antibiotic and Cr negative):
    • Caspofungin 70 mg IV q12h, then 50 mg q12h OR
  • Amphotericin 8.5–10 mg/kg
• Cryptococcosis:
  • Amphotericin 8.0–3.5 mg/kg IV for 1–2 wk OR
  • Fluconazole 25 mg/kg PO for 1–2 wk
• Coccidioidomycosis:
  • Fluconazole 400–800 mg PO for 1 yr OR
  • Amphotericin 8.0–3.5 mg/kg IV for 1 yr
• Histoplasmosis:
  • Fluconazole 400–800 mg PO q6–8 h OR
  • Amphotericin 8.0–3.5 mg/kg IV for 10–12 wk

SURGERY/OTHER PROCEDURES
• Obstructions from fungal bezoars require drainage.
• Access to upper tract: can facilitate drainage, antifungal irrigation, and extraction if needed.
• Perinephric abscesses can be drained percutaneously, but may require operative drainage if multiple loculations are present.
• Severe aspergillus kidney infections may require nephrectomy.
• Treatment of fungal prostatitis may require surgical intervention for prostatic resection or drainage of abscess in addition to medical therapy (46E).

• When fungal infections are found in the GU tract in patients without risk factors, a search for systemic disease is warranted.
• Disseminated fungal disease can seed the GU tract through the development of renal microabscesses.
• Fungal infections are encountered in varying geographic locales based on type.
• Treat candiduria in infants with low birth weight, those undergoing GU procedures, neutropenic patients, and symptomatic patients.
• Surgical drainage of fungal infections is indicated in cases of urinary tract obstruction.

161
GLOMERULONEPHRITIS, ACUTE

Christopher E. Keel, DO
Raju Thomas, MD, MHA, FACS

DESCRIPTION
- Inflammation of the glomerulus mediated through humoral and cell-mediated immune mechanisms including immunoglobulin, complement, and circulating T cells usually in response to an infection (typically streptococcal).
- The inflammation and immunologic response results in immune deposits in the glomerulus.
- Once symptoms is usually acute and includes oliguria, hypertension, hematuria, proteinuria, and renal impairment.
- Poststreptococcal acute GN is the onset of GN after a preceding group A β-hemolytic streptococcal infection, most commonly of the pharynx or skin.
- Most common glomerulonephritis affecting children.
- Synonym(s): Acute nephritic syndrome; Poststreptococcal glomerulonephritis.

EPISTEMIOLOGY
Incidence
- Poststreptococcal GN, the most common form, occurs most frequently in children between 2 and 10 yr of age but can occur at any age with a slight predominance of males over females.
- 10% cases are in adults, >40 yr of age.
- 20,000,000 yr

Prevalence
- Most patients have a complete recovery, with resolution of clinical signs within a few weeks.
- The reported incidence of chronic renal insufficiency is 0–20%.

RISK FACTORS
- Occurs with infection of specific types of group A β-hemolytic streptococci, and these vary by site of infection. It occurs more commonly after pharyngitis than pyoderma.
- Pharyngitis is associated with types 1, 3, 4, 12, 25, 49 with the more common sporadic variety.
- Pyoderma is associated with types 2, 49, 55, 57, 60.

Genetics
N/A

PATHOPHYSIOLOGY
- Tends to occur with impetigo in the late summer and with streptococcal pharyngitis in the winter.
- Note that cases of poststreptococcal GN have also been reported from other bacteria (Pneumococcus, Staphylococcus, Menigococcus) and after viral infections (chickenpox, hepatitis).
- The exact mechanism of renal injury from poststreptococcal GN is not clear. IgG and C3 deposits are found at the capillary wall and in the mesangium. It is unclear if the inflammatory response is due to circulating immune complexes, complexes in situ, or both.
- If the antin or antigens activate the alternative complement pathway and result in renal damage.

ASSOCIATED CONDITIONS
- Pharyngitis
- Hematuria
- Hypertension
- UTI
- Acute renal failure
- Rapid decrease in renal function heralds the syndrome of rapidly progressive glomerulonephritis

GENERAL PREVENTION
No specific prevention measures; prompt treatment of strep infections may reduce risk.

DIAGNOSIS

HISTORY
- Recent episode of pharyngitis or skin infection.
- Pharyngitis usually precedes renal disease by 8–14 days.
- Time between purulent skin disease and acute nephritis is widely variable.
- Serology varies from asymptomatic microhematuria to acute renal failure.
- Gross hematuria occurs in 30–50%.
- Volume overload occurs in up to 2/3 of patients and may be severe enough to cause congestive heart failure and pulmonary edema.
- Hypertension occurs in up to 80%.
- Severity may not correlate with the degree of volume overload.
- Hypertensive encephalopathy (seizures, confusion, coma) is the presenting feature in 5%.
- Often patient has contact with individuals complaining of similar symptoms.

PHYSICAL EXAM
- Patients may have periorbital edema, peripheral edema, HTN
- Transient oliguria will be present in half of patients

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis (1):
  - Proteinuria may be microscopic or gross and is present in all cases.
  - Microscopic analysis shows dysmorphic red blood cells and red cell casts.
  - >30% of red blood cells having dyssmorphic features is a highly sensitive test for glomerular disease.
  - Red blood cell casts present after acute pharyngitis episode is pathognomonic for poststreptococcal GN.
- Proteinuria may also be present and is usually mild (no more than 2+ on dipsticks), but some may have proteinuria to the nephrotic range.

- Evaluate proteinuria with a spot urine protein-to-creatinine ratio:
  - Normal <0.2.
  - Nephrotic range proteinuria being >2.0.
- Basic chemistry profile may reveal elevated BUN and creatinine consistent with ARF.
- Urine can be raised disproportionately to creatinine.
- Mild normochromic, normocytic anemia due to hemodilution.
- Hyperuricemia may be present due to volume overload.
- Acidemia and hyperkalemia may occur in those with severely depressed renal function.
- ESR will be elevated.
- Serum complement levels, in particular, C3 will be depressed early in the disease in 90%.
- Normalizes 2–4 wk after onset.
- Prior penicillin therapy may attenuate the fall in C3.
- If C3 remains depressed beyond this interval, look for other causes.
- Antistreptococcal O and antihyalurondase titers may be obtained and may be elevated in poststreptococcal GN.
- Not all strains of streptococci will cause these elevations and site of infection may affect which is present.

Imaging
- No imaging is indicated to identify poststreptococcal GN.
- CXR may identify fluid overload.

Diagnostic Procedures/Surgery
- Renal biopsy is not indicated in poststreptococcal GN unless symptoms persist or renal function deteriorates due to progressive disease.
- Renal biopsy, thus, indicated if:
  - Persistently low C3 beyond 8 wk
  - Persistent heavy proteinuria after 6 mo
  - Persistently low C3 beyond 8 wk
  - An acute presentation—nephritic syndrome, severe acute renal failure with estimated GFR <30 mL/min/1.73 m²
  - Arterial course—failure of renal function to improve after initial improvement during the acute phase which usually lasts no more than 2 wk

PHYSICAL EXAM
- Patients may have perihilar edema, peripheral edema, HTN
- Transient oliguria will be present in half of patients
Erythromycin is substituted if penicillin allergic.

Patients should be treated with a 10-day course of antibiotics to prevent the spread of the offending organism. This will not alter the course of the disease.

Erythromycin is substituted if penicillin allergic.

Family members of patients with acute GN should be cultured for group A β-hemolytic streptococci and treated if positive.

Supportive care, recovery is usually rapid and complete with an excellent prognosis.

> Furosemide 2–4 mg/kg/dose IV

Title: ONGOING CARE

PROGNOSIS

- Most patients have a complete recovery, with resolution of clinical signs within a few weeks.
- The reported incidence of chronic renal insufficiency is 0–20%.
- Microscopic hematuria may persist for months up to 2 yr, and mild proteinuria may persist for years following an episode of poststreptococcal GN.

COMPlications

- Rarely does poststreptococcal GN progress to chronic or rapidly progressive GN resulting in ESRD. Most cases resolve with no sequelae. Chronic renal failure or marked decline in glomerular filtration rate is very rare.
- It is rare to result in severe HTN, seizures, anuria, hyperkalemia, or death.
- Hyperensive retinopathy or encephalopathy.
- Rapidly progressive glomerulonephritis.
- Systemic lupus erythematosus.

SURGERY/OTHER PROCEDURES

Renal biopsy if indicated (see evaluation)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

GLOMERULONEPHRITIS, ACUTE

TREATMENT

GENERAL MEASURES

- Supportive care and reassurance.
- Monitor weight and serum sodium daily during acute phase.
- Bed rest does not influence rate of recovery.
- Antibiotics do not change the course of illness once established but should be given to reduce infection-related morbidity.
- Restrict protein until azotemia clears.

MEDICATION

First Line

- Treatment is supportive for this condition and directed at the effects of renal insufficiency and HTN.
- Sodium and water restriction is indicated in patients who show signs of fluid overload (400 mL/m2/d).
- Loop diuretics, calcium channel blockers, and vasodilators are mainstays in the treatment of resistant HTN.
- Furosemide 2–4 mg/kg/dose IV

Second Line

- Patients should be treated with a 10-day course of penicillin antibiotics to prevent the spread of the nephritogenic organisms. This will not alter the course of the disease.
- Erythromycin is substituted if penicillin allergic.
- Family members of patients with acute GN should be cultured for group A β-hemolytic streptococci and treated if positive.

CLINICAL/SURGICAL PEARLS

- Dynamic IPI on microscopic urinalysis suggest the diagnosis.
- Prior penicillin- or skin infection suggests diagnosis of acute glomerulonephritis.
- With supportive care, recovery is usually rapid and complete with an excellent prognosis.
GLomerulonephritis, Chronic

Eric Langewisch, MD
John M. Barry, MD, FACS

DESCRIPTION
Chronic glomerulonephritis is the loss of renal function caused by damage to glomeruli.

PATHOPHYSIOLOGY (2)
• Damage to glomeruli, often mediated through immune/inflammatory mediators, leads to decreased filtering surface and nephron mass.
• Remaining glomeruli are subjected to increased filtration pressure. This results in hypertrophy or remaining glomeruli.
• Increased glomerular pressure causes progressive sclerosis of glomerular and interstitial fibrosis, and progressive loss of functioning glomeruli.

ASSOCIATED CONDITIONS
See Risk Factors

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Elevated plasma creatinine from loss of renal function (3)
• Prior plasma creatinine values may help determine rate of renal function deterioration

RISK FACTORS
• Family history of hereditary GN (Alport syndrome, thin COL4A5 syndrome)
• Some cases of hereditary GN or nephritis (Alport syndrome, thin COL4A5 syndrome)
• Increased glomerular pressure causes progressive sclerosis of glomerular and interstitial fibrosis, and progressive loss of functioning glomeruli.

DIAGNOSIS
BASICS
• Chronic glomerulonephritis is the loss of renal function caused by damage to glomeruli.
• Often mediated by inflammation and cellular proliferation.
• Frequently associated with hematuria and proteinuria.
• Many forms of glomerulonephritis (GN) present azotemia. Progression from acute to chronic GN is variable.
• IgA nephropathy is the most common type of GN.

RISK FACTORS
• Family history of hereditary GN (Alport syndrome, thin COL4A5 syndrome)
• Acute GN (focal segmental glomerulosclerosis, membranous GN, diabetic nephropathy, membranous GN)
• Other systemic diseases (diabetes mellitus, multiple myeloma, amyloidosis, Henoch–Schönlein purpura, polycystic kidneys, Wegener’s granulomatosis)
• Family history of hereditary GN (Alport syndrome, thin basement membrane disease)

GENETICS
Some cases of hereditary GN or nephritis (Alport syndrome caused by a mutation of COL4A5 gene, usually X-linked and more severe in men; thin basement membrane disease)

HISTORY
• Often asymptomatic
• Past acute kidney disease
• Signs of uremia

PHYSICAL EXAM
• May be unremarkable
• Weight loss
• Hypertension
• Volume overload
• Elevated jugular venous pressure, pulmonary rales, pedal edema
• Signs of anemia
• Acneiform
• Pericardial rub

IMAGING
• Renal ultrasound to assess kidney size and cortical volume
• Advanced disease is associated with decreased renal size, increased echogenicity, and cortical thinning
• Kidneys usually normal sized with diabet nephropathy

DIAGNOSTIC PROCEDURE/SURGERY
• Renal biopsy can potentially diagnose different glomerular diseases.
• Biopsy may not be helpful in advanced disease

PATHELOGIC FINDINGS
• Renal biopsy may determine type of glomerular disease by pattern of injury and immune complex staining.
• With advanced disease and small kidneys on ultrasound, biopsy frequently shows advanced sclerosis/scarring and may not be able to determine etiology.
GLOMERULONEPHRITIS, CHRONIC

DIFFERENTIAL DIAGNOSIS
- Arteriolosclerosis (for weight control)
- Chronic interstitial nephritis
- Diabetic nephrosclerosis
- Diuretic abuse
- Hypertensive nephrosclerosis
- Nephrotoxin exposure
- Obstructive uropathy
- Prerenal disease
- Renal artery stenosis

TREATMENT
GENERAL MEASURES
- See GENERAL PREVENTION
- Referral to nephrology
- Treat specific glomerular disease (eg, prednisone or other immunosuppressive agents)
- Control blood pressure
- Renal replacement therapy may be necessary long term

MEDICATION
First Line
- Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) slow the decline of the glomerular filtration rate (GFR) in patients with diabetic and nondiabetic proteinuric nephropathies
  - ACEIs: Benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, quinapril, ramipril, others
  - ARB: Candesartan, eprosartan, irbesartan, losartan, telmisartan, valsartan
- Use may be limited by drug-induced hyperkalemia, increased plasma creatinine due to decreased glomerular pressure, or anemia

Second Line
- Diuretics to treat volume overload
- Additional antihypertensive agents to reach blood pressure goals
  - β-Blockers, calcium channel blockers, central α2-agonists (eg, clonidine), α1-antagonists, and direct vasodilators

SURGERY/OTHER PROCEDURES
- Access for dialysis
  - AV fistula or graft
- Hemodialysis access or peritoneal dialysis catheter
- Renal transplantation
- preemptive transplantation before dialysis results in better survival than transplantation after the initiation of dialysis

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Oral calcium supplements (1 g) and vitamin D (400–800 IU) for prophylaxis against osteoporosis
- Sodium bicarbonate has been shown to slow progressive kidney damage

COMPLICATIONS
- ESRD
  - Uremia
  - Volume overload
  - Hyperkalemia
  - Anemia
  - Acidosis
- Increased risk of cardiovascular disease
- Increased risk of mortality

FOLLOW-UP
Patient Monitoring
- Lab monitoring
  - Estimate glomerular filtration rate (GFR): BUN, plasma creatinine
  - Basic metabolic panel + phosphorous
  - Random urine protein/creatinine ratio
  - 24-hr urine protein
  - Blood pressure
  - Signs or symptoms of uremia

Patient Resources
- www.kidney.org/patients

GONORRHEA

Arpeet Shah, MD
Ahmer V. Farooq, DO

BASICS

DESCRIPTION
A sexually transmitted disease (STD) caused by the gram-negative diplococcal bacteria Neisseria gonorrhoeae.

EPIDEMIOLOGY
Incidence
- In the United States, gonorrhea remains the 2nd most commonly reported bacterial STD.
- The Center for Disease Control and Prevention (CDC) estimates 320,000 new cases per year with over half occurring in young adults aged 15–24.
- In 2011, CDC reported the rate of gonorrheal infections to be 104.2/100,000 persons, with over half occurring in young adults ages 15–24.
- Rates in the United States have drastically declined since the 1970s due to the public health measures.

RISK FACTORS
- Multiple sexual partners
- Unsafe sexual practices
- Alcohol and substance abuse
- Men who have 20–30% chance and women have a 70–80% chance after having 1 exposure

GENETICS
Individuals with inherited or acquired deficiency of complement components C3–C9 are more susceptible to localized and systemic gonococcal infections.

PATHOPHYSIOLOGY
- N. gonorrhoeae is not part of the normal flora of the genitourinary tract.
- Bacteria are introduced to the mucosal epithelial surface after direct contact with an infected individual.
- Attachment of the bacteria to the mucosal epithelium is mediated by pili (PilC1 and PilC2) and Opa proteins.
- Penetration of the organism into submucosal tissue usually takes 24–48 hr.
- Invasion of the epithelial triggers a strong response by neutrophils causing sloughing of epithelium, submucosal microabcesses, and purulent drainage.

ASSOCIATED CONDITIONS
- Always recommend testing for other STDs.
- Commonly associated with concomitant infection with Chlamydia trachomatis.

GENERAL PREVENTION
- Delaying onset of sexual activity and reducing the number of new partners.
- Conscientious condom use.

DIAGNOSIS

HISTORY
- Detailed history of sexual activity and partners.
- Incubation period of 3–14 days.
- Approximately 50% of infections in men are asymptomatic or mildly symptomatic; most common symptoms include dysuria and mucopurulent discharge.
- Approximately 50% of women have asymptomatic infection, most common symptoms include vaginal/cervical discharge, dysuria, urinary frequency, abdominal pain, and abnormal menstrual bleeding.
- Pregnancy does not change clinical presentation, but does lower incidence of pelvic inflammatory disease (PID).
- Anorectal infection is usually asymptomatic but can cause sore throat, pharyngitis and cervical adenitis.

PHYSICAL EXAM
- In men, mucopurulent urethral discharge may be seen; other signs include testicular/epididymal tenderness.
- In women, pelvic exam with speculum may demonstrate mucopurulent cervical discharge; other signs include cervical erythema, edema, and friability as well as cervical motion and adnexal tenderness.
- If suspecting anorectal infection, external inspection may reveal few or no signs of infection and anoscopy may be indicated with collection of specimens for culture.
- Pharyngeal cases may demonstrate exudative pharyngitis and cervical adenitis.
- Conjunctival cases demonstrate severe purulent discharge with crusting and lid edema.

DIAGNOSTIC TESTS & INTERPRETATION
Lab (2)
- Gram stain of urethral or endocervical discharge with a swab.
- Considered positive if neutrophils with intracellular gram-negative diplococci are visualized. Sensitivity and specificity of the Gram stain varies depending on the site of infection and the presence of symptoms.
- Culture has long been considered the gold standard for diagnosis.
- Advantages include high specificity and the ability to test for antibiotic sensitivity.
- Disadvantages include strict transport and storage requirements, specific environmental variables needed for growth (Thayer-Martin agar in CO2 incubator), and delays in obtaining results. Culture is the test of choice for extragenital sites of infection.
- Nucleic acid amplification test (NAAT) use molecular techniques to amplify specific DNA and RNA sequences.
- Advantages include higher sensitivity and comparable specificities of culture, minimal delay in results, noninvasive and self-collected samples, and identification of coinfections.
- Disadvantages include inability to screen for antimicrobial sensitivity. CDC now recommends NAAT as the 1st-line diagnostic test for uncomplicated urogenital gonorrheal infection.

Imaging
- Not indicated in uncomplicated cases.
- Computed tomography or pelvic ultrasonography if pelvic inflammatory disease (PID) or pelvic abscess suspected.
- Retrograde urogram if urethral stricture suspected.

Pathologic Findings
- Gram stain demonstrates gram-negative diplococci found inside of polymorphonuclear cells.

DIFFERENTIAL DIAGNOSIS (3)
- Other genitourinary infections including C. trachomatis, Trichomonas vaginalis, Mycoplasma genitalium, and Ureaplasma urealyticum, herpes simplex virus, bacterial vaginosis, and candidiasis.
- Also consider noninfectious sources such as foreign body, chemical irritation, allergic reaction, trauma, carcinoma, and leukоecytosis of pregnancy.
- For women who present with suspected PID, must rule out ectopic pregnancy and other intra-abdominal processes such as appendicitis.
**TREATMENT**

**GENERAL MEASURES**
- Patients with suspected active infection should abstain from sex until diagnosed and adequately treated.
- All sexual partners who have contacted the infected patient within 60 days of diagnosis should also be evaluated.
- Treatment with penicillin and tetracycline are not effective due to the high level of penicillinase-producing bacteria and poorly-mediated high-level tetracycline-resistant bacteria.

**Over the last decade, increasing mean minimum inhibitory concentrations of selective cephalosporins have indicated decreasing susceptibility and have impacted current treatment recommendations.**

- Macrolide resistance has also been reported.
- Fluoroquinolone resistance has impacted treatment options and is most prevalent in the states of California and Hawaii.
- Macrolide resistance has also been reported.

**MEDICATION**

**First Line (4)**
- For uncomplicated cases of urethral and endocervical gonorrheal infection, patients must also be treated for concomitant chlamydia infection unless diagnosed and adequately treated.
  - Ceftriaxone 250 mg IM in 1 dose PLUS azithromycin 1 g PO in 1 dose is the current gold standard.
  - Ceftriaxone 500 mg IM in 1 dose, cefotaxime 1 g IM in 1 dose, or cefuroxime 2 g IM with probenecid 1 g PO in 1 dose are alternatives for ceftriaxone.
  - If an injectable cephalosporin is not an option, alternatives include cefixime 400 mg PO in 1 dose or ceftazidime 400 mg PO in 1 dose. However, patients who receive these options should return in 1 week for microbiologic test of cure with culture.
  - Doxycycline 100 mg BID PO for 7 days is an alternative for ceftriaxone.

**Second Line**
- The management of those with a penicillin allergy depends on clinical suspicion of true allergy and the severity of the allergy.
- Most patients with documented penicillin allergy are not found to have an allergy after further testing and only 2% of those with a penicillin-positive skin test are true reactors.
  - Azithromycin 2 g PO in 1 dose monotherapy treats gonorrhea and syphilis, however, due to GI side effects and growing macrolide resistance, it is not a preferred regimen unless the patient has a severe penicillin allergy.
  - Spectromycin 2 g IM in 1 dose is a safe and effective alternative therapy for those with severe penicillin allergies, but is only available outside the United States.
  - Quinolones were once a 2nd line therapy, but due to drug resistance in 10–100% of strains depending on location, they are no longer recommended for the treatment of gonorrhea.

**SURGERY/OTHER PROCEDURES**
- Chronic gonorrhreal infection may lead to bulbar urethral strictures requiring urologic intervention.
- Gonorrhreal abscesses may require incision and drainage procedures.

**ADDITIONAL TREATMENT**
- Patient compliance regarding safe sex practices and abstinence for 7 days following treatment initiation.
- Patients should also be offered additional STD testing and pregnancy testing.

**Pregnancy considerations**
- Most common symptoms include mucopurulent discharge and dysuria. Especially in patients who are in their 20s.
- Maintain a high degree of suspicion for gonorrhea.
- In females, can cause PID leading to chronic pelvic pain, ectopic pregnancy, and infertility.
- Genital abscesses may occur in either sex requiring surgical intervention.
  - Fitz-Hugh-Curtis Syndrome – perihepatitis characterized by acute right or bilateral upper quadrant tenderness – may occur in either sex.
  - Urethral strictures requiring urologic intervention.

**COMPLICATIONS**
- Ocular infection with gonorrhea in adults may lead to corneal scarring and vision loss.
- Genital abscesses may occur in either sex requiring surgical intervention.
- Pelvic pain, Female
  - In females, can cause PID leading to chronic pelvic pain, ectopic pregnancy, and infertility.
  - Genital abscesses may occur in either sex requiring surgical intervention.

**ONGOING CARE**

**PROGNOSIS**
- 95% of uncomplicated genitourinary gonorrheal infections are cured by 1 course of treatment.

**CLINICAL/SURGICAL PEARLS**
- Maintain a high degree of suspicion for gonorrhea, especially in patients who are in their 20s.
- Most common symptoms include mucopurulent discharge and dysuria.
- Culture has been the gold standard for diagnosis, however, it is now being widely used as a 1st line diagnostic modality.
- 1st line treatment includes ceftriaxone 250 mg IM in 1 dose PLUS azithromycin 1 g PO in 1 dose.
- Antibiotic susceptibilities continue to change and vary by geographical location.
- Always counsel patients regarding safe sex practices.

**CODES**

ICD-9
- 098.11 Gonococcal cystitis (acute)
- 098.12 Gonococcal prostatitis (acute)
- A54.01 Gonococcal cystitis and urethritis, unspecified
- A54.22 Gonococcal prostatitis

ICD-10
- A54.00 Gonococcal infection of lower genitourinary tract
- A54.01 Gonococcal cystitis and urethritis, unspecified
- A54.02 Gonococcal prostatitis

ICD-11
- Gonococcal infection of lower genitourinary tract

**PEARLS**
- Prevented by routine screening for endocervical infection during pregnancy and prophylactic use of erythromycin ophthalmic solution.

**GONORRHEA**
GROIN/INGUINAL MASS, MALE AND FEMALE
Edouard J. Trabulsi, MD, FACS

ASSOCIATED CONDITIONS
- Chronic increased intra-abdominal pressure.
- STIs associated with lymphadenopathy.
- Penile cancer.

GENERAL PREVENTION
- Avoid chronic increase in intra-abdominal pressure that may encourage hernia formation.
- Avoid STIs.

DIAGNOSIS

HISTORY
- Onset of the mass (age, activity) and any associated symptoms.
- Family history of cryptorchidism.
- History of presence or absence of testes in the scrotum.
- History of pain or absence of tests in the scrotum, combined with tests in the scrotum.
- Evidence of adenopathy elsewhere, to suggest related lymphadenopathy.

PHYSICAL EXAM
- Patient should be examined in standing position.
- A cough impulse usually suggests an inguinal hernia.
- Transillumination test, if positive, may suggest a hydrocele.
- Tender testis suggests epididymitis, testicular torsion, or appendicitis.
- Absent testis suggests undescended testes.
- Ulceration may suggest a sexually transmitted disease.
- Groin tenderness: Likely infection is the etiology.

DIFFERENTIAL DIAGNOSIS
- Cryptorchidism.
- Inguinal hernia.
- Lymphadenopathy.
- Neoplasms, Trauma, Infections, Vasculitis, Vasculitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab:
- Blood tests:
  - Full blood count and ESR
  - Renal function tests and electrolytes
  - Syphilis serology, if indicated
  - HIV serology, if indicated
  - LSG (lymphangiography/wirework) serologic test, if suspected
- Swab and culture the base of any lesions to diagnose genital herpes, syphilitic ulcer, chancroid (Nesseriofila ducreyi).

Imaging (2):
- US can confirm hernia and help to see the tests within the inguinal canal. Not sensitive for intra-abdominal tests.
- Doppler US for vascular conditions (Valsava maneuver should be performed during exam).
- CTVUS can diagnose obscure hernias. Also can identify related lymphadenopathy.
- Arteriography may help diagnose femoral artery aneurysm.
- Viscoscopy or Doppler US will help diagnose saphenous veins.

Diagnostic Procedures/Surgery
- Laparoscopy: Can be diagnostic and therapeutic for hernia and intra-abdominal tests.
- Exploratory surgery is necessary in many cases for both diagnosis and treatment.
- Femoral nerve block or fine needle aspiration (FNA) for definitive diagnosis of lymphadenopathy.
- Chromosomal and hormonal analysis in relation to bilateral undescended testes.

Pathologic Findings
- Cryptorchidism:
  - Decreased number of Leydig and Sertoli cells
  - Failure to develop primary spermatocyte
- Peritubular fibrosis
- Lymphadenopathy:
  - Can be metastatic or inflammatory cause.

ACRONYMS
- MINT
- Viral hepatitis
- Mumps
- Clinical findings
- Nephrotic syndrome
- Trauma
- Viral hepatitis
- Mumps
- Nephrotic syndrome
- Trauma

**TREATMENT**

**GENERAL MEASURES**  
Management is based on the cause of the mass and can vary from antibiotic therapy, biopsy, or further imaging for more extensive adenopathy.

**MEDICATION**

**First Line**  
- **Infectious:**  
  - Infection requires treatment with specific antibiotics.  
  - For STD-related adenopathy, see specific chapter.

**Second Line**  
- **Hydrocele:**  
  - Self-exam for testicular masses
  - Requires follow-up for fertility
  - Increased risk of trauma and torsion
  - Malignancy: Increased risk of malignancy in absence of treatment

**SURGERY/OTHER PROCEDURES**

- **Cryptorchidism:**  
  - Treatment varies based on testis location
  - Surgeon preference
  - Corrective surgery does not reduce the chances of malignancy

**COMPLICATIONS**

- **Hernia:**  
  - Congenital hernias are repaired by ligating the processus vaginalis
  - Testicular Torsion
  - Self-exam for testicular masses
  - Hernia, for recurrence

**COMPLICATIONS**

- **Lymphadenopathy:**  
  - Infection requires treatment with specific antibiotics
  - Biopsy: If the mass is reducible, strongly suggests a hernia

**PROGNOSIS**

- Depends on the etiology of the mass

**ADDITIONAL TREATMENT**

**Radiation Therapy**

- N/A

**ADDITIONAL THERAPIES**

- Complementary & Alternative Therapies
  - N/A

**ONGOING CARE**

- **Lymphadenopathy:** Requires follow-up for chronic infection, response to treatment.

**CLINICAL/SURGICAL PEARLS**

- The differential diagnosis varies greatly by the age of the patient.
- If the mass is reducible, strongly suggests a hernia.

**TREATMENT**

**GENERAL MEASURES**

- Management is based on the cause of the mass and can vary from antibiotic therapy, biopsy, or further imaging for more extensive adenopathy.

**MEDICATION**

**First Line**

- **Infectious:**  
  - Infection requires treatment with specific antibiotics.
  - For STD-related adenopathy, see specific chapter.

**Second Line**

- **Hydrocele:**  
  - Self-exam for testicular masses
  - Requires follow-up for fertility
  - Increased risk of trauma and torsion
  - Malignancy: Increased risk of malignancy in absence of treatment

**SURGERY/OTHER PROCEDURES**

## GYNECOMASTIA

**Samuel Walker Nickles**

**James S. Rosoff, MD**

### BASICS

**DESCRIPTION**
- Gynecomastia (GM) is benign enlargement of the male breast due to proliferation of ductal elements.
- Pseudogynecomastia/aplasia is an increase in breast adipose tissue. This can be distinguished by careful physical exam of subareolar tissue and comparison to adjacent adipose tissue.

**EPIDEMIOLOGY**
- Incidence (1)
  - Approximately 2,000 cases of male breast cancer are diagnosed in the United States annually
  - Prevalence
    - 30–65% of men have palpable breast tissue and at autopsy 40–55% of men have histologic evidence of GM
  - Age related: Asymptomatic GM is 60–90% in neonates, 50–60% in adolescents, and up to 70% in men aged 50–69 yr

**RISK FACTORS**
- Alcoholism
- Endocrinopathies
- Medications
- Obesity
- Renal failure

**Genetics**
- Klinefelter syndrome (47, XXX) is strongly associated with GM
- An increased risk of male breast cancer has been reported in families with a BRCA2 mutation

**PATHOPHYSIOLOGY**
- Male breast tissue has both androgen and estrogen receptors.
- Androgens inhibit breast development and estrogens stimulate it. GM develops when there is an imbalance of these two influences (ie, androgen deficiency or excess estrogen) or lack of tissue response to them.

**ASSOCIATED CONDITIONS**
- Prostate cancer
- Testicular tumors
- Carcinoma
- Renal failure

**GENERAL PREVENTION**
- With hormonally induced GM, prophylactic breast insufflation may reduce GM

---

### DIAGNOSIS

**HISTORY**
- Age of patient and onset of symptoms (pubertal, GM of aging)
- Associated bruises or chills, breast trauma, nipple discharge
- Medical conditions (cirrhosis, chronic kidney disease, HIV, hyperthyroidism)
- Medications/drugs
- History of cryptorchidism
- Sexual history. Sexual maturation, changes in libido, erectile dysfunction, infertility

**PHYSICAL EXAM**
- General appearance, weight, amount of adipose tissue (contains aromatase capable of peripheral conversion of androgens to estrogen)
- Secondary sexual characteristics such as body hair distribution and phallic size
- Breast exam
  - Breast exam: Special attention should be paid to distinguish true GM from pseudogynecomastia (unilateral vs. bilateral) If unilateral should be concerned for potential male breast cancer), firm and mobile vs. fixed, skin dimpling, any nipple discharge, position of axillary lymph nodes
- Genitourinary exam with special attention to the testicular exam

**DIAGNOSTIC TESTS & INTERPRETATION**
- Lab
  - Basic studies: Creatinine, LFTs, thyroid function tests, serum testosterone
  - Further testing as needed
    - Serum estradiols (estradiol, estrogen)
    - LH, FSH, prolactin
    - Tumor markers: AFP, β-hCG
    - Adrenal androgens, serum DHEA, urinary 17-ketosteroids

**Imaging**
- Nuclear US if abnormal tumor markers
- CT of the abdomen and pelvis if abnormal levels of adrenal androgens
- Mammography if cancer suspected

**Diagnostic Procedures/Surgery**
- Breast biopsy for suspected breast cancer

**Pathologic Findings**
- Proliferation of ductules embedded in a connective tissue stroma
- Over about 12 months, the breast tissue evolves into a quiescent stage, in which the amount of stroma and fibrous increases and the ductules become less prominent. glandular acini are rare (2)

**DIFFERENTIAL DIAGNOSIS**
- Physiologic GM Normal in neonatal boys secondary to maternal estrogen exposure.
- Occurs in 60–90% of neonatal boys and resolves within several weeks after delivery.
- Pubertal GM results from the earlier rise in estrogens in early puberty. As the normal ratio of estrogen to testosterone is restored later in puberty the GM resolves.
- 50–70% of boys develop GM during puberty. 25% of men still have GM at 20 yr of age.

**GM of aging:**
- The hypothalamic–pituitary–testicular axis is variable in age-related decline. Some men have elevated gonadotropins while others will be normal.
- Adiposity increases with age which leads to increased peripheral conversion.
- Sex hormone–binding globulin (SHBG) levels rise with age and decreasing bioavailable testosterone.
- Medications may also play a part in GM in older men.

- Testosterone secreting tumors:
  - Leydig cell tumors are rare tumors of the testis; 85–90% are benign, most are nonpalpable. Some Leydig cell tumors can directly secrete estrogens. This increases estrogen levels and inhibits LH secretion, suppressing testicular production of testosterone.
  - Seminal cell tumor: Converts androgens to estrogens leading to a direct increase in circulating levels of estrogens.
  - Remaining adrenal cortical tumors are generally malignant and poorly differentiated. These cancers directly secrete estrogens as well as steroid precursors that may be aromatized to estrogens in peripheral tissues. Increased estrogen suppresses LH-mediated production of testosterone as well.

- HCG-secreting tumor such as choriocarcinoma stimulates Leydig cells to preferentially secrete estrogens. Many HCG-secreting tumors also will take up steroid precursors such as DHEA and convert them to active estrogens.

- Increased peripheral aromatization to estrogens:
  - Familial estrogen excess syndrome. The enzyme aromatase (P450 arom or CYP19A1) catalyzes the conversion of steroidal precursors to estrogens.
  - Estrogen receptor agonists:
    - Therapeutic administration of estrogens such as DES (diethylstilbestrol) may be used to treat men with prostate cancer and can lead to GM.
    - Estrogens may also be used to stimulate breast development in male-to-female transsexuals.
    - Unintentional exposure may occur transnationally by sexual intercourse with a partner that uses topical estrogens. Occupational exposure is also possible. Estrogens can be found in hair creams, embalming creams, and in the production of medicinal estrogen products.
  - Marijuana smoke, digoxin, testosterone, or other aromatizable androgens.

- Androgen deficiency or resistance:
  - Primary or secondary hypogonadism: Testicular failure from any cause may result in GM. Testosterone deficiency leads to elevated LH which increases extralateral production by remaining Leydig cells. Increased estrogens lead to elevated levels of SHBG, further decreasing free testosterone.
  - Klinefelter syndrome is the most common genetic disorder associated with hypogonadism and infertility in men. GM is present in 50–70% of cases. Klinefelter syndrome is the only cause of GM with an established risk of breast cancer (20-fold increase).

- Deficits in genes critical for testosterone production may also lead to decreased testosterone production.
Gynecomasia

• Androgen resistance disorders:
  – In both partial and complete androgen insensitivity syndrome, cellular response to androgens is inadequate (elevated gonadotropins and increased serum testosterone) due to lack of negative feedback.

• Refeeding associated GM:
  – Recognized after WW II when imprisoned men resumed normal diets and developed tender GM. Starvation is associated with hypogonadotropic hypogonadism. With resumption of a healthy diet and regaining weight the hypothalamic-pituitary-testes axis returns to normal, resulting in transient estrogen excess. May also explain GM associated with several chronic diseases.

• Renal failure:
  – Many men with chronic kidney disease develop GM upon initiation of hemodialysis. Before initiation of diuretics are often nauseaed, anorexic, and on protein-restricted diets. The pathogenesis is thought to be similar to refeeding GM.

• Cirrhosis:
  – Studies have shown that the prevalence of GM in cirrhosis is no different than hospitalized age-matched controls. Hormonal changes in cirrhotic liver disease may increase the risk of GM.

• With longstanding GM, or those that refuse medical therapy:
  – Removal of the offending drug or exogenous source of estrogen if possible
  – Adrenal tumors: Adrenalectomy
  – Testosterone replacement therapy in androgen-deficient men may result in partial regression of GM, especially if breast enlargement is of recent onset.

• Breast cancer:
  – Dose: 12 Gy in 2 fractions to 20 Gy in 5 fractions
  – Suspicious lesions should be biopsied.

• Hypothyroidism:
  – With longstanding GM, or those that refuse medical therapy:
  – Aromatase inhibitors such as testolactone and anastrozole have been used but not proven as effective as tamoxifen.
  – Tamoxifen, 10 and 20 mg/d, for 3–9 mo with 90% resolution. Additionally, raloxifene and clomiphene citrate have also been used.

• Breast cancer:
  – Increased serum prolactin: Antipsychotic agents, amphetamines, diazepam, antidepressants (tricyclics and SSRIs).

• Gastrointestinal:
  – PUD:
  – Radiation Therapy
  – Metoclopramide.

• Alcohol abuse:
  – Androgen receptor blocker: Flutamide, bicalutamide, raloxifene, tamoxifen, spironolactone.

• Medications:
  – Diabetes Mellitus:
  – HIV:
  – Hyperthyroidism:
  – Cirrhosis:
  – Renal failure:
  – Refeeding associated GM:

• Androgen receptor blocker: Flutamide, bicalutamide, raloxifene, tamoxifen.

• Increased serum prolactin: Antiproliferotic agents, oestrosapride.

• Possible: Refeeding GM, scrotalized, androgen insensitivity. Known as: HAART, human growth hormone, anabolic agents, anabolic agents, antiandrogens, antipsychotics, antidepressants (tricyclics and SSRIs).

• Breast cancer:
  – Rare in men, are similar to those of female breast cancer.
  – A hard fixed mass, ulceration, bloody nipple discharge, or lymphadenopathy should raise suspicion.

• Suspsicious lesions should be biopsied.

• Median age of onset is thought to be 50 yrs.

• Complementary & Alternative Medicine:
  – Glutamine, Probiotics, St. John’s Wort, CoQ10.

• Radiation Therapy
  – Prophylactic breast irradiation has been used prior to initiation of estrogens or androgen blockade for blockade for prostate cancer patients.

• Second Line
  – Aromatase inhibitors such as testolactone and anastrozole have been used but not proven as effective as tamoxifen.

• Testosterone replacement therapy in androgen-deficient men may result in partial regression of GM, especially if breast enlargement is of recent onset.

• SURGERY/OTHER PROCEDURES
  – With longstanding GM, or those that refuse medical treatment, cosmetic surgical excision and reconstruction may be performed

• Adrenal tumors: Adrenalectomy

• ADDITIONAL TREATMENT

• Radiation Therapy
  – Prophylactic breast irradiation has been used prior to initiation of estrogens or androgen blockade for blockade for prostate cancer patients.

• Additional Therapies
  – Radioactive oral ibutrol or propylthiouracil for hypothyroidism.

• Complementary & Alternative Therapies

• N/A

ONGOING CARE

PROGNOSIS

• Generally favorable prognosis.

• Patient main concerns: Ruling out breast cancer and cosmetic correction.

COMPLICATIONS

Psychological stress

FOLLOW-UP

Patient Monitoring

No regular follow-up is necessary for patients who have physiologic GM and are untroubled by their symptoms and do not have symptoms suggestive of malignancy.

Patient Resources

CODES

ICD9

• 278.00 Obesity, unspecified

• 611.1 Hypertrophy of breast

• 758.7 Klinefelter’s syndrome

ICD10

• E66.8 Obesity, unspecified

• N82 Hypertrophy of breast

• Q88.4 Klinefelter syndrome, unspecified

CLINICAL/SURGICAL PEARLS

• Breast cancer is rare in males, representing ~1% of all cases of breast cancer.

• Klinefelter syndrome is the only cause of gynecomastia with an established risk of breast cancer.

171
Hematospermia

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION
- Hematospermia (sometimes referred to as hemospermia) as the presence of visible blood (foul or altered) in the ejaculate (not specified with regard to how many episodes or overall duration).
- Semen can be described as bright red, coffee-colored, rusty, or darkened; appearance may change as blood ages.
- May occur as a single episode or persist chronically.
- Usually a self-limited and benign condition.

EPIDEMIOLOGY
Incidence
- Accounts for 0.02% (1/5,000) new patient visits to a urology clinic; seen in 0.5% of men presenting for prostate cancer screening [1].
- Mean presenting age of 57 yr old.
- Mean duration is 1–24 mo.
- In men <40 yr old, cause is almost always due to an inflammatory or infectious process.
- Only 2.4–3.5% of cases of hematospermia result in the diagnosis of a malignancy, typically >40 yr old.

Prevalence
Not truly known

RISK FACTORS
- Recent genitourinary trauma, surgery (prostate biopsy), infection
- Prostatic, bacterial
- Prolonged abstinence from or frequent ejaculation
- Use of anticoagulant medication
- Systemic coagulopathy/bleeding disorder
- Use of anticoagulant medication
- Any cause of bleeding

Genetics
None

PATHOPHYSIOLOGY
- Often occurs in isolation
- Pathophysiologic causes include:
  - Inflammatory and infection
  - Ductal obstruction and cysts of the accessory sexual glands
  - Neoplasms
  - Vascular abnormalities
  - Systemic factors
  - Inherited factors

ASSOCIATED CONDITIONS
- Nonmalignant prostatic disease (26%)
- Hypertension (HTN) (15%)
- Genital tuberculosis (TB) (11%)
- Prostate cancer (1%)

GENERAL PREVENTION
None known

DIAGNOSIS

HISTORY
- Duration and amount of bleeding
- Sexual history/frequency
  - Sexual history/frequency
  - Sexual behavior: synchronous or diurnal
  - Isolated episodes or periods of abstinence or after frequent ejaculation
  - Associated voiding disorders
    - Hematuria
    - Dysuria
    - Urethral discharge
  - Fever
  - INR for patients on coumadin
  - Liver disease
  - Neurologic conditions
  - Fatigue
  - LUTS

PHYSICAL EXAM
- Assess blood pressure (BP)
- Abdominal exam for masses
- Perineal/rectal:
  - Proctoscopy
  - Rectal examination
- Surgical:
  - Axillae
  - Induration may indicate TB
- Abnormal stool:
  - Hematuria
  - Metastatic disease
  - Hemorrhoids

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- urine culture (for acid-fast bacilli and parasites if indicated)
- Serum white cell count and coagulation profile (international normalized ratio [INR])
- Complete blood count (CBC) if blood dyscrasia
- Suspected: stool for patients on coumadin
- Tuberculin skin test should be considered, particularly in patients with exposure history or if originate from or recent travel to endemic areas.
- Serum analysis can be used to confirm diagnosis of true hematospermia and, in case of schistosomiasis, eggs may be noted. If performed, semen culture should also be sent.
- Urine cultures/urine samples for the diagnosis of sexually transmitted infection if indicated.
- In patients >40 yr or with risk factors for prostate or bladder malignancy:
  - Prostate serum antigen (PSA)
  - Urine cytology
- Imaging
  - Transrectal ultrasound (TRUS) of the prostate:
    - To evaluate the prostate, seminal vesicles (SV’s), and possible Mullerian duct remnants
    - To evaluate the prostate, seminal vesicles (SV’s), and possible Mullerian duct remnants
  - Magnetic resonance imaging (MRI): facilitates diagnostic procedures such as biopsy, puncture
- Should be 1st imaging study for hematospermia
- Ultrasound:
- Renal ultrasound:
  - For the kidneys, ureters, and bladder:
  - Cross-sectional or endorectal coil MRI may be obtained
- Should be used if TRUS is not diagnostic or if TRUS is equivocal
- Cross-sectional or endorectal coil MRI may be obtained
- Diagnostic Procedures/Surgery
- Indicated for patients with evidence of tumor or infection
- Cystoscopy:
  - Allows visualization of urethral inflammation and opening of ejaculatory ducts
- Critical for ruling out urothelial carcinoma

Pathologic Findings

Risk

LABORATORY

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Pathologic Findings

Risk
DIFFERENTIAL DIAGNOSIS

- Infections:
  - Caused by SVs, prostate, or urethra
  - Prostatitis
  - Urethritis
  - Proctitis
  - Urethral infections
  - Viral
  - Herpes simplex
  - Cytomegalovirus
  - Human papilloma virus/cytomeblyoma
  - Bacterial
  - TB
  - Chlamydial trachomatis
  - Gonorrhea
  - Syphilis
  - Parasitic
  - Chlamydia
  - Mycobacterial disease (Tuberculosis)
  - Ductal obstruction and ots of accessory glands:
    - Epididymal duct cysts
    - SV diverticulum
    - Urethral structure
    - Urethral ots
    - Wolffian duct ots
    - Prostatic ots
  - Neoplasms:
    - Benign
      - Prostatic cysts
      - Wolffian duct cysts
      - Utricular cysts
      - Urethral stricture
      - Ejaculatory duct cyst
    - Malignant
      - Prostatic adenocarcinoma
      - Prostatic ductal adenocarcinoma
      - Adenocarcinoma of the SV
      - Adenocarcinoma, sarcoma, stromal tumor, lymphoma, malakoplakia
      - SV adenocarcinoma, squamous cell carcinoma, malakoplakia, metastases to prostate or SVs (metastatic melanoma to the SVs or prostate, may result in melanospermia)
      - Urethra
      - Testes

- Epididymal Mesotheloma
- Vascular abnormalities
  - Arteriovenous malformations
  - Prostatic varicosities
  - Hemangiomata
- Systemic factors
  - Renal insufficiency conditions
  - Hemophila
  - Von Willebrand disease
  - HIV
  - Chronic liver disease
  - Amyloidosis of the SVs
- Iatrogenic causes
  - Prostate biopsy (most common)
  - Genitourinary (GU) instrumentation
  - Extraperitoneal shock wave lithotripsy (ESWL) of distal urotheal stones
  - Radiotherapy (occurs in 28% of seed cases)
  - Prostate radiation
  - MRI
  - Postbiopsy (vasoogenitum vasa)
  - Postrectotomy

TREATMENT

GENERAL MEASURES

- If an underlying cause is identified (ie, bleeding disorder, GU TB, chlamydia infection), initiate appropriate medical management.
- Patients should be made aware that this is very common after prostate biopsy
- Spontaneous hematospermia is rarely associated with malignancy
- Most commonly a benign condition that resolves spontaneously and reassurance is appropriate

MEDICATION

First Line

- In men ≤40 yr old without an obvious cause of hematospermia after workup (normal physical exam, negative urine studies):
  - Reassurance and expectant management
  - Empiric antibiotic therapy with doxycycline or fluoroquinolone
  - Trial of 5α-reductase inhibitor (finasteride, dutasteride) for 3 mo (3C)
- While a similar approach can be taken in men >40 yr old, diagnostic workup should be more exhaustive and prostate biopsy should be considered if PSA or DRE indicates.

Second Line

SURGERY/OTHER PROCEDURES

- Prostatic calculi: Transurethral resection
- Cystoscopic resection of any lesions seen on exam
- Prostatic calculi: Transurethral incision
- Epididymal mesothelium: Removal
- Urethral adenoma:
  - Transperineal or transurethral approaches
  - Interferon or surgery
- SVs or prostate, may result in melanospermia

Additional Treatment

RADIATION THERAPY

ADDITIONAL READING

SYMPTOMS

- Patients should be reassured, as should their partners.
- A significant number of cases remain idiopathic even after a full workup.
- Hematospermia following prostate biopsy may take several months to clear.

  - D48.9 Coagulation defect, unspecified
  - N41.9 Inflammatory disease of prostate, unspecified
  - R86.1 Hematospermia

- CLINICAL/SURGICAL

- Pearls

- Hematospermia is usually a benign and self-limited condition, particularly in men <40 yr old.
- It is often resolve spontaneously in all age groups.
- Work-up only indicated if persistent or if other associated symptoms (such as hematuria).
- Expected symptoms following prostate biopsy and can last for several weeks.
- Treatment should be directed toward underlying cause if identified.

- Outcomes

- N/A

- Prostate Biopsy: Infections and Complications
HEMATURIA, GROSS AND MICROSCOPIC, ADULT

Megan M. Merrill, DO
Surena F. Matin, MD, FACS

BASICS

DESCRIPTION
- Hematuria may be gross (GH) (visible) or microscopic (MH).

RISK FACTORS (5)
- Male gender
- Age
- History of irritative voiding symptoms
- Recent febrile illness
- Pelvic radiation

EPIDEMIOLOGY
Incidence
- Incidence of various disorders in patients who present with MH or GH: (3)
  - No diagnosis — 64.5%
  - UTI — 13%
  - Bladder cancer — 12%
  - Renal disease — 9.8%
  - Stone disease — 3.6%
  - Renal cancer — 0.6%
  - Prostate cancer — 0.4%
  - Upper tract cancer — 0.1%

Prevalence
- Prevalence of asymptomatic MH varies with age and gender, and ranges from 0.19–21% (4).

PATHOPHYSIOLOGY
- Macroscopically:
  - Blood clots that have a vermiform (worm-like) appearance suggest the origin of hematuria to be the upper tract.
  - Blood clots that are amorphous suggest the origin to be the lower urinary tract—bladder or prostate.
- On microscopic analysis:
  - RBCs in the urine that are isomorphic and have smooth, round membranes and uneven hemoglobin distribution suggests urologic disease.
  - RBCs that are dysmorphic with irregular shapes and uneven hemoglobin distribution suggests glomerular disease.

ASSOCIATED CONDITIONS
- Neoplasms
- UTI
- Glomerulonephritis
- Anatomic abnormalities of urinary tract (eg, UPJ obstruction)
- Benign prostatic enlargement

GENERAL PREVENTION
- Adequate fluid intake, especially for patients with history of calculi
- Smoking cessation
- Occasional/infrequent consumption of alcohol

DIAGNOSIS

HISTORY
- Age and sex: Age >35, bladder cancer is the most common cause of hematuria, urologic cancer is more common in males; females may have vaginal bleeding (4).
- Timing of GH during urinary stream:
  - Initial hematuria—anterior urethral pathology
  - Terminal hematuria—bladder neck, prostate, or urethra inflammation/pathology
  - Hematuria throughout—vesical or upper-tract origin

- Associated pain:
  - Painless hematuria suggests bladder cancer
  - Flank pain, GH, and abdominal mass is pathognomonic of renal cell carcinoma
  - Unilateral or bilateral pain can be caused by calculus (most common), tumor, or blood clot
  - Ureteral colic/flank pain can cause hematuria associated with dysuria, urgency, and frequency

- Presence of clot—indicates significant degree of hematuria and higher probability of significant pathology
  - Amorphous clots—bladder/prostate origin
  - Vermiform clots—upper tract origin
  - Lower urinary symptoms (frequency, urgency, etc.):—bladder can cause hematuria
  - Incomplete bladder emptying can predispose to bladder stones and infection
  - Straining to urinate or spaying of urinary stream can indicate a urethral stricture
  - Activity/exercise-induced hematuria should be excluded

- Trauma—significant crush injury or burn may result in myoglobinuria, abdominal or pelvic trauma may cause urinary tract injury
  - Recent upper respiratory infection—associated with GIN or immunoglobulin A (IgA) nephropathy
  - Medical or surgical history:
    - Renal or urologic disease or surgery
    - Recent urologic instrumentation (including catheterization)
    - Sexually transmitted diseases (STDs)
    - History of tuberculosis (TB)
  - History of pelvic radiation
  - History of autoimmune diseases and bleeding disorders
  - Current medications
    - Antiplatelets
    - Analgesic abuse
  - History of smoking tobacco
  - Menstrual history: Vaginal bleeding can be mistaken for hematuria

- Family history
  - Primary renal disease
  - Hypertension (HTN)
  - Adult polycystic kidney disease
  - Alport syndrome
  - Urothelial malignancy
  - Occupational risk factors
  - Exposures to chemicals or dyes (aromatic amines, benzene) in rubber, petroleum, and dye industries—risk of urothelial carcinoma
PHYSICAL EXAM

- Vital signs
  - Hypertensive evaluate for renal parenchymal disease, chronic kidney disease (CKD) or renal failure, renal cystic disease or renal vascular disease; may be hypertensive if hematuria present/urate stone
- Palpation
  - Abdomen or renal palpation
- Rectal examination (DRE)

Pelvic examination:

- Flank lacerations, contusions or rib fractures—underlying renal injury
- Flank tenderness:
  - Hematuria, gross and microscopic, adult
- Palpable abdominal or flank masses
- Heart murmurs: Subacute bacterial endocarditis
- Hearing loss: Alport syndrome
- Rashes
  - May indicate a systemic process
- Vital signs
  - Color
  - Nodularity suggest cancer
- Urinalysis: Must include standard urine dipstick and digital rectal exam (DRE)

- Pyuria – suggests infection
- Blood: Suggests recent or ongoing bleeding
- Proteinuria: Heavy (3–4+), indicates intrinsic renal disease
- Specific gravity: Poorly concentrated urine—low specific gravity (<1.005) suggests nephropathic with renal impairment or intrinsic renal disease
- Leukocyte esterase and/or nitrite positive – pyelonephritis, pyelitis, pyelonephritis (nephrotic analysis is negative)
- False-positive dipoles for blood: Cholesterol crystals (bile, bacterial peritoneal, myoglobinuria, hemoglobinuria (microscopic analysis is negative)
- False-negative dipoles for blood: Reducing agents (high dose vitamin C), urine pH >5.5
- Microscopic
  - Pyuria – suggests infection
  - Red cell casts – pathognomonic of glomerular bleeding
- Crystalluria – suggests urolithiasis

Phase-contrast microscopy or urinary sediment: Differentials: granular (renal) and nonglomerular bleeding based on the presence of distal RBC’s (80%) in glomerular bleeding, sensitivity of 95% and specificity 100% (2)

- Urine culture
  - If analysis suggests infection

Urinary cytology
- Recommended for all patients with risk factors or irritative voiding symptoms. Not recommended as part of routine evaluation for asymptomatic MH
- Sensitivity for detecting bladder cancer 40–76% (1) (Better at detecting high-grade urothelial carcinomas and CIS)
- Negative result does not rule out malignancy
- Physical cells can be seen with calculi or inflammation
- NMP22, IFA stat, and triixsys are alternatives; not considered standard of care but can be useful in some cases of bladder cancer

- Renal function tests (creatinine and BUN)
- CBC – anemia may be due to GH or chronic renal failure

Diagnostic Tests & Interpretation Lab

- Urinalysis: Must include standard urine dipstick and microscopic evaluation
  - MH is defined as ≥3 RBC/high-powered field (hpf) in urinary sediments from ≥2 of ≥3 properly obtained urine specimens (catheterized sample if vaginal contamination or phimosis) (2)
  - Color
    - Bright red: Suggests recent or ongoing bleeding with urologic/anatomic-urethral
    - Brown (tea-colored): Suggests old blood/cystitis or medical renal disease (GR)
  - Dipstick (4)
    - Specific gravity: Poorly concentrated urine—low specific gravity (<1.005) suggests nephropathic with renal impairment or intrinsic renal disease
    - Proteinuria: Heavy (3–4+) suggests GR or renal disease
    - Leukocyte esterase and/or nitrite positive – pyelonephritis, pyelitis, pyelonephritis (nephrotic analysis is negative)
    - False-positive dipoles for blood: Cholesterol crystals (bile, bacterial peritoneal, myoglobinuria, hemoglobinuria (microscopic analysis is negative)
    - False-negative dipoles for blood: Reducing agents (high dose vitamin C), urine pH >5.5
    - Microscopic
      - Pyuria – suggests infection
      - Red cell casts – pathognomonic of glomerular bleeding
      - Crystalluria – suggests urolithiasis

- Imaging
  - Plain abdominal imaging: Limited utility in initial evaluation of hematuria, gross and microscopic, adult
  - Myoglobinuria, hemoglobinuria (microscopic analysis is negative)
  - If hypertensive evaluate for renal parenchymal disease, chronic kidney disease (CKD) or renal failure, renal cystic disease or renal vascular disease; may be hypertensive if hematuria present/urate stone
  - Febrile UTI, concern for urologic malignancies
  - NMP22, IFA stat, and triixsys are alternatives; not considered standard of care but can be useful in some cases of bladder cancer

- Renal function tests (creatinine and BUN)
- CBC – anemia may be due to GH or chronic renal failure

Diagnostic Procedures/Surgery

- Cystoscopy (5)
  - Should be performed in all patients >35 yr old with MH or GR
  - Patients: <35 yr; cystoscopy performed if significant risk factors for urologic malignancies present: irritative voiding symptoms, tobacco history, chemical exposure, etc.
  - Retrograde pyelography (RPG), cystoscopy as clinically indicated

Pathologic Findings

Based on primary cause

HEMATURIA, GROSS AND MICROSCOPIC, ADULT

- MIBI
  - Alternative imaging modality when CT scanning is not advised (contrast allergy, renal insufficiency, metastatic implants)
  - Provides excellent visualization of small renal masses and arteriovenous malformations but has less utility for stones
  - Gadodiurnum contract in avoidance of patients with creatinine >2 mg/dL (71 mL/min), due to risk of progressive systemic fibrosis (hypertrophic systemic fibrosis [HSF])

- Renal US
  - Detects renal cystic disease, renal masses, hematuria
  - Less sensitive for detecting stone disease but useful in children and pregnancy, when radiation is contraindicated
  - Operator-dependent, large body habitus can limit utility

- Bladder US
  - Useful to assess posterior residuals, can detect larger bladder tumors, bladder calcification and diverticulum, although less sensitive than CT scan

- VCUG
  - Voiding cystourethrogram (VCUG), cystoscopy as clinically indicated

175
HEMORRHAGIC DISEASES OF THE URINARY TRACT

DIFFERENTIAL DIAGNOSIS

- Pseudohematuria
  - Drugs:
    - Reddish color: Pyridium, doxorubicin, phenytoin, salicylates, amin, others
    - Brown color: Cascara, iron supplements, riboflavin, other
  - Vegetables: Beets
  - Dyes or pigments
  - Myoglobin and free hemoglobin
  - Menstrual period contamination
  - Dysfunctional uterine bleeding
- Congenital/inherited:
  - Cystic renal disease
    - Polycystic kidney disease
    - Medullary sponge kidney
    - Medullary cystic disease
  - Benign familial hematuria or thin basement membrane nephropathy
  - Alport syndrome
  - Inherited renal tubular disorders that can lead to urolithiasis
    - Renal tubular acidosis type I
    - Cystinuria
    - Ocuprosis
  - Hemolytic-uremic abnormalities
    - Bleeding dyscrasias
  - Sickle hemoglobinopathies
- Anatomic causes
  - Urethral and ureteric strictures
  - Phimosis
  - Posterior urethral valves
  - Urethral caruncle
  - Diverticula
  - UPJ obstruction
  - Obstructive uropathy: Hydronephrosis
  - Venous outflow reflux
  - Vascular malformations: Hemangiomas
- Traumatic
  - Abdominal and pelvic injury
  - Degree of hematuria is a poor indicator of injury severity
  - Urterogent trauma after abdominal, pelvic, or urinary tract surgery
  - Exercise-induced hematuria
  - Foreign bodies: Catheters, stents, self-introduced, etc.
  - Inflammatory
    - Urinary tract and specific infections
    - Radiation: Radiation cystitis and nephritis
  - Metabolic
    - Uric crystalluria
    - Hypercalcuria
    - Hyperuricosuria
  - Neoplastic: Any benign or malignant GU lesion
  - Drug-induced
    - Nephritic or tubular damage
    - Analgesic abuse
  - Miscellaneous
    - Bladder stone
  - Arterial emboli or thrombosis
  - Renal vein thrombosis
  - Endometriosis of the urinary tract—female with cyclic hematuria
  - Benign essential hematuria

TREATMENT

GENERAL MEASURES

- The standard urologic evaluation should include urinalysis, urine culture, cystoscopy if risk factors, CTU and cytology as outlined above (see also “Hematuria Algorithm”)
- Treatment depends on etiology
  - Consider and rule out pseudohematuria or medical causes of hematuria based on presentation, history, lab data, or if evaluation for anatomic lesion is negative
- Gross hematuria
  - If patient is urinating without difficulty and has no blood clots can treat conservatively—increase oral fluid intake
  - For patients with ureteral retention: Place a large-bore 3-way Foley catheter (large-bore 2-way or rigid catheter may be more effective to clear clots) and hand irrigate out all clots, followed by continuous bladder irrigation (CBI) with sterile saline or water
  - More severe hematuria or hemodynamic instability may require surgery—cystoscopy with clot evacuation/fulguration
- Microscopic hematuria
  - Work-up can be done in the office setting and usually requires no immediate monitoring or treatment unless associated with trauma

MEDICATION

First Line

- Not treated primarily by medications
  - Aminocaproic acid (Amicar)—for intractable gross hematuria (6)
    - Inhibitor of fibrinolysis
    - Rare but serious side effects of thrombotic events and renal failure
  - Finasteride may be effective for prostatic hemorrhage

Second Line

- Transfuse RBCs if indicated for extreme acute blood loss
- Continuous bladder irrigation (CBI) with normal saline for persistent hematuria with clots
- Consider bladder irrigation with 1% Alum if GH persists
- Cystoscopy, clot evacuation, fulguration if conservative treatment fails
HEMATURIA, GROSS AND MICROSCOPIC, ADULT

ADDITIONAL TREATMENT

Radiation Therapy

- N/A

Additional Therapies

- N/A

Complementary & Alternative Therapies

- Hyperbaric oxygen therapy (HBO) has been shown to be effective in hematuria caused by radiation-induced cystitis if delivered within 6 mo of initiation of hematuria.

ONGOING CARE

PROGNOSIS

Based on etiology of the hematuria

COMPLICATIONS

Hypotension and anemia may result on degree and chronicity of blood loss

FOLLOW-UP

Patient Monitoring

- Monitor hemodynamic status if severe gross hematuria, especially if associated with trauma

Patient Resources

- Urinary Care Foundation, http://www.urinaryhealth.org/urine/index.cfm?article=113

REFERENCES

ADDITIONAL READING

CODES

ICD9
- 599.0 Urinary tract infection, site not specified
- 599.71 Gross hematuria
- 599.72 Microscopic hematuria

ICD10
- R31.0 Gross hematuria
- R31.2 Other microscopic hematuria
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Gross or microscopic hematuria in any patient should be evaluated, especially when significant risk factors are present (age >35, smoking history, exposure to chemicals/dyes, irritative voiding symptoms).
- Risk of urologic malignancy is 5 times higher in patients who present with gross hematuria.
- Cytology is recommended for patients with risk factors; however, a negative result does not rule out malignancy.
- CTU is the imaging test of choice for evaluating hematuria from the upper tract.
- Cystoscopy should be performed on any patient >35 yr of age presenting with unexplained MH or GI.

ON SEVENTY SEVEN
HEMATURIA, GROSS AND MICROSCOPIC, PEDIATRIC

Douglas W. Storm, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

ASSOCIATED CONDITIONS
Depends on the bleeding source

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Microscopic hematuria considered clinically significant if >5–10 RBCs/hpf
- Recommend that 2 of 3 urinalyses show microscopic hematuria over 2–3 wk before work-up initiated (1,2)[A]
- False-negative results occur with high urine specific gravity or with high ascorbic acid concentration
- False-positive results occur in presence of myoglobin, medications (eg, rifampin, pyridium, etc.), bile pigments, and oxidizing agents (eg, household bleaches)
- Urinalysis
  - Proteinuria
    - If 1+ or 2+ child should be evaluated for postural proteinuria
    - 2+ or greater proteinuria child should be evaluated for glomerulonephritis and nephrotic syndrome
  - RBC casts are highly specific for glomerulonephritis
  - Dysmorphic RBCs predict glomerular bleeding
  - Dysmorphic RBCs predict glomerular bleeding with a sensitivity of 93–95% and a specificity of 96–100%
  - WBCs, bacteria, leukocyte esterase, nitrites suggest UTI
  - Recommend urine culture to verify UTI and identify bacteria causing the infection
- Other urinary tract infections
  - Complete blood count CBC
  - Plasma IgA levels (may be increased with IgA nephropathy)
  - Urinalysis
    - Glycosuria (indicative of poststreptococcal GN)
    - Total hematuria suggests upper tract source
    - Initial or terminal hematuria suggests lower tract source
    - WBC casts are highly specific for glomerular bleeding
  - Urinalysis
    - Proteinuria
      - If 1+ or 2+ child should be evaluated for postural proteinuria
      - 2+ or greater proteinuria child should be evaluated for glomerulonephritis and nephrotic syndrome
    - RBC casts are highly specific for glomerulonephritis
    - Dysmorphic RBCs predict glomerular bleeding
    - Dysmorphic RBCs predict glomerular bleeding with a sensitivity of 93–95% and a specificity of 96–100%
    - WBCs, bacteria, leukocyte esterase, nitrites suggest UTI
    - Recommend urine culture to verify UTI and identify bacteria causing the infection
- Other blood tests
  - Serum creatinine, BUN, electrolytes (if renal insufficiency noted)
  - Complete blood count CBC
  - Anti-glomerular basement membrane (anti-GBM) (indicative of poststreptococcal GN)
  - CBC to evaluate for anemia
    - Hemoglobin, hematocrit
    - Erythrocyte sedimentation rate
    - Erythrocyte counts (can be elevated in cases of SLE and ON)
    - Plasma IgG levels (may be increased with IgG nephritis and HSP)
  - Other urine tests
    - Urine calcium to creatinine ratio varies by age, but generally <0.18; if >0.18 suggests high 24-hr excretion of calcium >4 mg/kg/day
  - Other lab tests
    - Uric acid (to rule out gouty arthritis)
  - Other imaging
    - Renal and bladder sonography
      - Evaluate for renal parenchymal disorders, stones, tumors, and anatomic abnormalities
      - Voiding cystourethrogram (VCU/G)
      - Not routinely performed in work-up of hematuria
      - May be done if hematuria is felt to be in conjunction with laboratory findings
      - Can be useful for evaluation of renal disease or anatomic abnormalities or after recent trauma
DIFFERENTIAL DIAGNOSIS
Dependent on the cause of the bleeding

Diagnostic Procedures/Surgery
- Cystoscopy
- Renal biopsy
- Cystoscopy
- Renal biopsy

Pathologic Findings
- Hematuria

DIAGNOSTIC PROCEDURES
- Cystoscopy
- Renal biopsy

COMPLICATIONS
- Unstable BP, renal insufficiency, fevers
- HTN, edema, oliguria, significant proteinuria, RBC casts

PROGNOSIS
Based on underlying cause of the hematuria and any interventions delivered

FOLLOW-UP

Patient Monitoring
- Current recommendation of American Academy of Pediatrics is screening urinalysis at age 5 yr
- Urinal measurements of height, weight, and BP measurements after age 3 yr

Patient Resources
- www.chop.edu/healthinfo/hematuria.html

HEMORRHAGE FOLLOWING TURP OR TURBT

Frank M. Nezu, MD
Mohamed T. Ismail, MD

**BASICS**

**DESCRIPTION**
Significant gross hematuria with or without clot retention that occurs following transurethral resection of the prostate (TURP) or transurethral resection of bladder tumor (TURBT).

**EPIDEMIOLOGY**
- Occurs in up to 11% of patients, typically within the 1st 3 mo after TURP (181B).
- TURP is associated with a 2.9% transfusion rate (181B).
- 2.2–3.3% of patients require recatheterization, clot evacuation, or return to OR for bleeding after TURP (118[A]).

**RISK FACTORS**
- Excessive bleeding/straining/constipation
- Inadequate hemostasis/coagulation of bleeding vessels
- Infection
- Medications: Warfarin, heparin, low molecular weight heparins, aspirin, thienopyridine (clopidogrel), etc.
- Trauma
- Undermining of bladder neck

**Genetics**
Patients with deficiencies in the clotting cascade (e.g., hemophilia) or other coagulopathies are more prone to hemorrhage.

**GENERAL PREVENTION**
- Obtain sufficient hemostasis intraoperatively
- Stop anticoagulants or other blood-thinning medications prior to surgery
- Delay starting anticoagulant medications postoperatively if possible, although this practice has been questioned (141B)
- Gentle postoperative catheter traction
- See reductive inhibitors, taken pre operatively, may reduce surgical blood loss intraoperatively (181A).
- See reductive inhibitors, do not decrease rates of postoperative clot retention (181A).

**PATHOPHYSIOLOGY**
- Anesthetic technique (regional or general) appears to have no impact on TURP related bleeding.
- Inadequate hemostasis/coagulation of bleeding vessels.
- Nausea may cause constipation and increased intra-abdominal pressure
- NSAIDs are not contraindicated after TURP, they do not increase risk of postoperative adverse events (181A).

**DIAGNOSIS**

**HISTORY**
- Color of urine, presence of clots
- Patient is not able to void (clot retention)
- History of TURP/TURBT—timing, complications, catheter removal
- Use of anticoagulation or similar medications
- Excessive straining or trauma, last bowel movement
- History of clotting disorder
- History of prostate cancer

**PHYSICAL EXAM**
- General: Pallor, dehydrated, acutely ill
- Vitals: Hypotensive or tachycardic
- Abdomen: Bladder distended or palpable
- Genitalia: Edematous, ecchymotic

**DIAGNOSTIC TESTS & INTERPRETATION**
- CBC to assess for anemia
- Creatinine level for obstruction
- Urinalysis, urine culture
- Coagulopathy screen (platelets, PT/PTT) particularly if there is suggestion of bleeding from other sites

**Imaging**
- Bladder US or pelvic CT to evaluate for large organized clot within bladder

**Differential Diagnosis**
- Bleeding from lower GU tract source: Urethra, prostate, bladder
- Bleeding from upper GU tract source: Ureter, renal pelvis, kidney

**TREATMENT**

**GENERAL MEASURES**
- Limit physical activity, encourage bed rest
- Limit fluids and avoid constipation through stool softeners
- Adequate hydration, IV fluid resuscitation
- Bladder drainage and clot evaluation with large-caliber hematuria catheter
- Continuous bladder irrigation (CBI) via 3-way Foley catheter to clear clots and prevent new clots from forming in the bladder
- Foley traction, additional inflation of Foley balloon
- Cessation of anticoagulants or blood-thinning medications
- Check CBC and coagulation profile
- MR CT transabdominal if necessary, vitamin K and/or FFP if coagulopathic
- CIB with intravesical alum or silver nitrate
- These are reported but rarely necessary.
  - Hyperbaric oxygen
  - Antimicrobial and (African) antibacterial
  - Hormonal manipulation: LHHR agonists
  - Urinary diversion with bilateral PCNs
  - Salvage radical prostatectomy
  - Selective arterial prostatic embolization (SAPED) (181A)
HEMORRHAGE FOLLOWING TURP OR TURBT

MEDICATION

First Line
- Antibiotics if infected
- Stool softeners
- 5α-reductase inhibitors such as finasteride or dutasteride (although will not have an acute effect)

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Transurethral clot evacuation with fulguration and cautery (laser or electrocautery) of prostate if bleeding does not subside within a reasonable timeframe
- Post-TURBT hemorrhage, more expeditious clot evacuation and fulguration

ONGOING CARE

PROGNOSIS
- The mortality rate for hemorrhage after TURP and TURBT is unknown
- Whether hemorrhage after TURP increases the risk of future prostatic bleeding has not been described in the literature
- Use of stool softeners and avoidance of constipation for several weeks after TURP and TURBT seems advisable

COMPLICATIONS
- Severe anemia and/or hypovolemic shock can lead to syncope and/or MI

FOLLOW-UP
- Patient Monitoring
- Can be managed on the floor setting with staff who are accustomed to managing catheters and CBI
- Serial CRs, blood transfusions as necessary
- Monitor coagulation profile, FFP if needed

Patient Resources
- N/A

REFERENCES

ADDITIONAL READING

- Hematuria, Gross and Microscopic, Adult
- Hemorrhage, Postop, Urologic Considerations
- Hemorrhagic Cystitis
- Urine, Abnormal Color

CODES
- ICD9: 599.71 Gross hematuria
- 998.11 Hemorrhage complicating a procedure

ICD10
- N99.820 Postproc hemor/hematom of a GU sys org fol a GU sys procedure
- N99.820 Hemorrhage

CLINICAL/SURGICAL PEARLS
- Proper patient selection, identify patients at risk for bleeding with attention to medications.
- Attention to detail at the end of TURP/TURBT, complete hemostasis and evacuation of specimen.
- Avoid contamination postoperatively.
- In patient with clot retention a large-bore catheter is used to evacuate all clots and start continuous bladder irrigation (CBI) immediately.
**HERPES SIMPLEX, GENITAL**

Michael Perrotti, MD

### BASICS

**DESCRIPTION**
- Herpes simplex is a common sexually transmitted virus infection.
- Herpes simplex virus (HSV)
  - HSV-2 is the most common cause of genital herpes.
  - Can be caused by HSV-1 (oral sex during HSV-1 outbreak).
- An increasing proportion of anogenital herpetic infections in some populations has been attributed to HSV-2 infection.

**EPIEMIOLOGY**

- **Incidence**
  - 0.5–1 million new cases of genital herpes per year in US.
- **Prevalence**
  - ~45 million people in US have genital herpes.

**RISK FACTORS**

- Sexual contact with an infected person.
- Unprotected sexual intercourse.
- Multiple sexual partners.

**PATHOPHYSIOLOGY**

- Transmission can occur by anal, vaginal, or oral sex.
- Prophylactic and antiviral therapy may reduce transmission.
- Transmission can occur by anal, vaginal, or oral sex.
- Prophylactic and antiviral therapy may reduce transmission.
- HSV-2 infection is most frequent during the first 12 mo after acquiring HSV-2.

**ASSOCIATED CONDITIONS**

- HSV.
- Other STIs.

### GENERAL PREVENTION

- Monogamous seronegative partner.
- Condom use.
- Randomized trials have demonstrated that male circumcision (MC) reduces heterosexual acquisition of various STI/STD including HSV type 2, and it reduces genital ulcer disease among female partners.

### DIAGNOSIS

**HISTORY**

- Patients may experience prodrome before appearance of lesions.
- Tingling, pruritus, paresthesias.
- Fever.
- Headache.
- Painful genital lesions.
- Dysuria.

**PHYSICAL EXAM**

- Multiple shallow genital ulcers that may be vesicular.
- However, these classical painful multiple vesicular or ulcerative lesions may be absent in some.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- Polymerase chain reaction.
- Direct fluorescence antibody.
- Viral culture.

**Imaging**

- MRI in suspected CNS disease.

**Diagnostic Procedures/Surgery**

- Biopsy of vesicular or ulcerative lesions may be absent in some.
- Patient's history.
- Viral culture.
- Type-specific serology testing.
- Both lab-based assays and point-of-care tests that provide results for HSV-2 antibodies from capillary blood or serum.
- The sensitivities of these glycoprotein G type-specific tests for HSV-2 antibody vary from 85–98%, are false-negative at early stages of infection. The specificities are ≥96%.
- False-positive results can occur, especially in patients with a low likelihood of HSV infection.

**DIFFERENTIAL DIAGNOSIS**

- Acute UTI.
- Anogenital gonorrhea.
- TREPONEMA pallidum.
- Drug eruption.
- Behcet's disease.

### TREATMENT

**GENERAL MEASURES**

- No cure is available.
- Encourage safe sex practices to reduce transmission.
- Unprotected sexual intercourse.
- Multiple sexual partners.
- Avoidance of sexual activity during recurrences.
- Antiviral medications can prevent or shorten outbreaks.
- Daily suppressive therapy can reduce recurrences.
- Topical therapy with antiviral drugs offers minimal clinical benefit.
- Treatment guidelines based on most current CDC recommendations.

**MEDICATION**

**First Line**

- Acyclovir, valacyclovir, and famciclovir are safe for use in immunocompromised patients in the doses recommended for treatment of genital herpes.

**Second Line**

- Valacyclovir 500 mg once a day might be less effective than other valacyclovir or acyclovir dosing regimens in patients who have very frequent recurrences (≥10 episodes per year).
HERPES SIMPLEX, GENITAL

- Episodic therapy for recurrent genital herpes (2)
  - Requires initiation of therapy within 1 day of lesion onset or during the prodrome that precedes some outbreaks.
  - Provide patient with a supply of drug or a prescription for the medication with instructions to initiate treatment immediately when symptoms begin.
  - Acyclovir 400 mg TID for 5 days OR 800 mg PO TID for 2 days
  - Famciclovir 125 mg PO BID for 5 days OR 1,000 mg PO BID for 1 day OR 500 mg once, followed by 250 mg BID for 2 days
  - Valacyclovir 500 mg PO BID for 5 days OR 1 g PO QD for 5 days

SURGERY/OTHER PROCEDURES
- Sitz baths
- Foley catheter for retention of urine associated with sacral nerve root involvement

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies
- In complicated HSV infection (central nervous system disease, disseminated HSV), the Centers for Disease Control recommend intravenous acyclovir (5–10 mg/kg) every 8 hr for 2–7 days or until clinical improvement.
- Suppressive or episodic therapy with oral antiviral agents is effective in decreasing the clinical manifestations of HSV among HIV-positive persons.
- Complementary & Alternative Therapies
  - None noted to be effective

ONGOING CARE

PROGNOSIS
- Symptoms may last 2–4 wk if untreated
- Symptoms less severe in nonprimary compared to person without pre-existing HSV immunity
- Treatment during primary infection lessens symptoms less severe in nonprimary compared to person without pre-existing HSV immunity
- Patient Monitoring
  - Patient’s education concerning the natural history of the disease, potential for recurrent episodes, asymptomatic viral shedding, and the risks of sexual transmission.
  - At 1st episode of genital herpes, advise the patient that suppressive therapy is available and effective in preventing symptomatic recurrent episodes
  - Encourage patients to inform their current sex partners that they have genital herpes and to inform future partners before initiating a sexual relationship.
  - The risk for HSV-2 sexual transmission can be decreased by the daily use of valacyclovir by the infected person. Episodic therapy does not reduce the risk for transmission and its use should be discouraged for this purpose among persons whose partners might be at risk for HSV-2 acquisition (4).
  - Symptomatic sex partners should be evaluated and treated in the same manner as patients who have genital lesions. Asymptomatic sex partners of patients who have genital herpes should be questioned concerning histories of genital lesions and offered type-specific serologic testing for HSV infection.

ICD10
- A60.00 Herpesviral infection of urogenital system, unspecified
- A60.04 Herpesviral vulvovaginitis
- A60.9 Azoogential herpesviral infection, unspecified

CLINICAL/SURGICAL PEARLS

- It is estimated that 1 in 5 adults in US is infected with HSV, but that many are asymptomatic and do not know that they are infected with the virus.
- Most infected individuals have recurrent episodes of painful genital ulcers.
- The 1st episode usually occurs a few weeks following initial infection with the virus and may last 2–3 wk.
- HSV recurrences generally decrease in frequency over time.
Adequate Treatment of LUTS

GENERAL PREVENTION

BPH and erectile dysfunction in men

PATHOPHYSIOLOGY

Risk Factors

Prevalence

Incidence

Epidemiology

Description

Akhil Das, MD, FACS

Patricia Lewandoski, MD

HESITANCY AND INTERMITTENCY

Introduction

Hesitancy and intermittency are commonly characterized as obstructive (emptying) symptoms. These symptom patterns also include:

- Protracted dribbling
- Straining to void
- Decreased force of stream
- Incomplete bladder emptying

Epidemiology

Incidence

Obstructive urinary symptoms and age are highly correlated.

Patient symptom reporting is influenced by sociodemographic and cultural factors.

Hesitancy and intermittency is primarily related to BPH and occurs mostly in men.

Prevalence

- Age-stratified prevalence of moderate to severe lower urinary tract symptoms (LUTS) in men:
  - 40–50 yr old: ∼20%
  - 50–60 yr old: ∼30%
  - 60–70 yr old: ∼40%
  - 70–80 yr old: ∼50%

Risk Factors

- Bladder outlet obstruction:
  - In men, primarily related to benign prostatic hyperplasia (BPH), bladder neck contracture, bladder stones, urethral valves, urethral stricture disease, and prostate cancer.
  - In women, primarily caused by pelvic floor prolapse, cystocele, bladder stones, urethral stricture disease (rarely)

- Detrusor underactivity:
  - Idiopathic
  - Neuropathic (Diabetes, Parkinson disease, etc.)
  - Non-neurogenic (Dysfunctional voiding)

- Obesity is associated with a higher incidence of LUTS

Genetics

N/A

Pathophysicsology

- Bladder outlet obstruction causes increased resistance to urinary flow due to various etiologies (BPH, bladder neck contracture, bladder stones, urethral valves, urethral stricture disease, and prostate cancer).

- In women, primarily caused by pelvic floor prolapse, cystocele, bladder stones, and urethral stricture disease (rarely)

- Detrusor underactivity:
  - Idiopathic
  - Neuropathic (Diabetes, Parkinson disease, etc.)
  - Non-neurogenic (Dysfunctional voiding)

- Obesity is associated with a higher incidence of LUTS

Associated Conditions

BPH and erectile dysfunction in men

General Prevention

Adequate treatment of LUTS

Diagnosis

History

- Quantification of lower urinary tract symptoms
  - AUA/IPSS symptom index should be used.
  - Other obstructive voiding symptoms should be assessed.
  - Consider voiding diary if history is unclear.
  - Assess for irritative voiding symptoms:
    - Cystitis/contamination: Can present with acute, severe obstructive symptoms.
  - History of hematuria:
    - Urethral stricture
    - Bladder/urethral stones
    - Bladder mass
  - Certain pelvic procedures can result in detrusor underactivity.
  - Other medical conditions:
    - Certain neurologic conditions and diabetes can cause detrusor underactivity.
  - Prior pelvic irradiation can affect bladder contractility.
  - History of STD may predispose patients to urethral stricture disease.
  - Medications:
    - Antimuscarinics may lead to obstructive symptoms.
    - Other obstructive voiding symptoms should be assessed.

- Other obstructive voiding symptoms:
  - Straining to void
  - Decreased force of stream
  - Bladder mass

- Bladder stones

- Urethral stricture disease

- Bladder neck contracture (ie, after prostate surgery)

- BPH—common cause of hesitancy and intermittency

- Lower urinary tract symptoms, such as hesitancy or intermittency, according to the AUA guidelines for BPH

Physical Exam

- Abdominal Exam: Palpate for a distended bladder.
- Digital Rectal Exam (DRE) should be performed:
  - Prostate size
  - Prostatic nodularity
  - Rectal tone
  - Prostatic nodularity

- Neurologic exam:
  - Sensory examination
  - Motor examination
  - Reflexes

- Urethral lesions should also be assessed.

- Prostatic nodularity

- Anal sphincter tone

- General mental status

- Certain neurologic conditions and diabetes can cause detrusor underactivity.

- Certain neurologic diseases and diabetes can cause detrusor underactivity.

- Bladder mass

- Bladder stones

- Urethral stricture

- Bladder neck contracture (ie, after prostate surgery)

- BPH—common cause of hesitancy and intermittency

- Lower urinary tract symptoms, such as hesitancy or intermittency, according to the AUA guidelines for BPH

Diagnostic Tests & Interpretation

- Lab:
  - Urinalysis by dipstick testing or microscopic exam of the sediment should be performed to screen for hematuria and UTI.
  - If UTI suspected: Urine culture.
  - Serum PSA should be assessed in men with at least a 10 yr life expectancy.
  - Renal function tests (BUN and creatinine) are NOT recommended as part of the initial work-up of hesitancy and intermittency unless warranted by history, exam, or lab evaluation.
  - If urethral stricture disease is suspected, retrograde urethrography (RUG) may be helpful.
  - Transrectal US should be reserved for patients with an increased suspicion of prostate cancer undergoing prostate needle biopsy

- Imaging:
  - Upper tract evaluation (CT scan, IVP, or US) is NOT recommended as part of the initial work-up of hesitancy and intermittency unless warranted by history, exam, or lab evaluation.

  - If urethral stricture disease is suspected, retrograde urethrography (RUG) may be helpful.
  - Transrectal US should be reserved for patients with an increased suspicion of prostate cancer undergoing prostate needle biopsy

- Diagnosing Procedures/Surgery

- Urinary flow rate should be considered:
  - May be helpful in patients with complex medical history.
  - Should be performed in patients who are to undergo invasive therapy, as this may predict response to surgery.

- Cystoscopy and/or transurethral resection

- Cystourethroscopy should be considered in patients with possible urethral stricture.

- Bladder mass

- Bladder stones

- Urethral stricture disease

- Bladder neck contracture (ie, after prostate surgery)

- BPH—common cause of hesitancy and intermittency

- Lower urinary tract symptoms, such as hesitancy or intermittency, according to the AUA guidelines for BPH

- Diagnosing Procedures/Surgery

- Urinary flow rate should be considered:
  - May be helpful in patients with complex medical history.
  - Should be performed in patients who are to undergo invasive therapy, as this may predict response to surgery.

- Cystoscopy and/or transurethral resection

- Cystourethroscopy should be considered in patients with possible urethral stricture.

- Bladder mass

- Bladder stones

- Urethral stricture disease

- Bladder neck contracture (ie, after prostate surgery)

- BPH—common cause of hesitancy and intermittency

- Lower urinary tract symptoms, such as hesitancy or intermittency, according to the AUA guidelines for BPH

- Differential Diagnosis

- Bladder outlet obstruction
  - BPH—common cause of hesitancy and intermittency in men
  - Bladder neck contracture (ie, after prostate surgery)

- Urethral stricture disease

- Bladder stones

- Foreign body

- Cancer (prostate, bladder, urethra)

- Prostatitis

- UTI

- Bladder neck dyssynergia
• Detrusor-sphincter dyssynergia
• Pelvic organ prolapse
• Detrusor underactivity (more common cause of hesitancy and intermittency in women):
  - Cholinergic dysfunction
  - Parkinson disease
  - Multiple sclerosis
  - Intervertebral disc
  - Radiation syndromes
  - Sexual and/or psychosocial dysfunction
  - Medications: Anticholinergic drugs are less likely to cause sexual dysfunction but more likely to cause urinary hesitancy

TREATMENT

GENERAL MEASURES
• When the effect of LUTS on quality of life was studied, most important factors for seeking treatment were the severity and degree of bother.
• Treatments are tailored to the degree of bother and the severity of the disease.
• Review medications (anticholinergics, sympathomimetics, and opioids) to determine if any are potential cause; consider alternatives.
• Micturition diary:
  - Limit fluid intake
  - Avoid diuretics
  - Avoid coffee, tea, alcohol which may irritate the bladder

MEDICATION (2)

First Line
• For patients with evidence of infection, appropriate antibiotic therapy should be initiated.
• For men with hesitancy and intermittency presumably due to BPH/BOO:
  - α1-adrenergic antagonists (alfuzosin, doxazosin, tamsulosin, terazosin, ubidesiride) reduce resistance at the bladder outlet and provide symptom relief.
  - At maximal doses, all agents are felt to be equally effective.
  - Side effect profiles may include orthostatic hypotension, retrograde ejaculation, asthenia, and nasal congestion.
• 5α-reductase inhibitors (5ARI) (finasteride 5 mg and dutasteride 0.5 mg) reduce prostate volume, prevent progression of BPH, and improve symptoms in clinical trials.
  - These drugs can cause decreased libido, sexual dysfunction, and reduce PSA by ~50% and are of little use in men without evidence of clinical BPH.
  - Combination therapy: MTPS study showed a 67% 5-yr risk reduction in BPH progression in men on combination therapy (doxazosin and finasteride) compared to placebo and better than either agent alone (39% and 34%, respectively).

Second Line
• Combination therapy combining an 5ARI with an α1-blocker may be useful
• If ED and BPH/BOO coccur daily tadalafil (2.5–5 mg PO QD) can be used

SURGERY/OTHER PROCEDURES
• Unilateral urethral disease and/or bladder neck contractures should be addressed using appropriate endoscopic or open procedures.
• Cyclosporine and/or pelvic floor relaxation in women should be addressed surgically if indicated.
• For men with hesitancy and intermittency presumably due to BPH/BOO who do not respond to medical management:
  - Transurethral resection of the prostate (TURP) remains the gold standard surgical approach in patients who do not respond to medical management to BPH.
  - Can be combined with various laser techniques to facilitate tissue hemostasis and removal.

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
• Behavioral interventions, such as timed voiding or double voiding

Complementary & Alternative Therapies
• Saw palmetto (Serenoa repens) has been reported to improve LUTS due to BPH/BOO. Randomized clinical studies have produced contradictory results.

ONGOING CARE
PROGNOSIS (3)
• 25% of untreated patients with moderate-to-severe LUTS presumably due to BPH/BOO experience clinical progression of symptoms within 5 yr.
• Randomized clinical trials of patients receiving α1-blocker therapy indicate that >75% will report a 25% improvement in symptoms within 3 mo of initiating treatment.
• 5–10% of men with moderate-to-severe LUTS will fail medical therapy and will require surgical intervention for their condition.

COMPLICATIONS
• Patients with disease progression who do not receive appropriate treatment may experience the following complications:
  - Renal insufficiency
  - UTI
  - Stone formation
  - Acute urinary retention
  - Secondary bladder dysfunction

FOLLOW-UP

Patient Monitoring
• After appropriate treatment has been initiated and patients report improvement, annual follow-up should include:
• History and physical exam, urinalysis, PSA
• – Uroflowmetry and postvoid residual urine as needed

• Bladder Outlet Obstruction (R40)
• Lower Urinary Tract Symptoms (LUTS)
• Prostate, Benign Hypertrophy
• Prostatitis, General

HESITANCY AND INTERMITTENCY

CRITICAL CODES
ICD10
• R39.19 Other difficulties with micturition
• R39.13 Splitting of urinary stream
• R39.14 Urinary retention
• R39.18 Other abnormality of urination

ICD9
• 788.69 Other abnormality of urination

CLINICAL/SURGICAL PEARLS
• Hesitancy and intermittency is often associated with BPH and generally represents LUTS associated with an obstruction.
• Increasing hesitancy may be seen before an episode of retention.
• In men, the incidence increases with age.
• Pressure flow studies are helpful in determining obstruction vs. detrusor underactivity.
HIV/AIDS, UROLOGIC CONSIDERATIONS
Daniel C. Parker, MD
Michael A. Pontari, MD

ALERT
The American Urological Association (AUA) policy statement now considers circumcision to be of a health benefit, citing a 50–60% risk reduction in HIV transmission in some African nations.

BASICS
DESCRIPTION
• HIV disease results from the acquired deficiency of cellular immunity caused by the human immunodeficiency virus (HIV).
  – Hallmarks:
    • Reduction of the helper T-lymphocytes in the blood and the lymph nodes
    • Development of opportunistic infections (Pneumocystis carinii pneumonia, cytomegalovirus infections, tuberculosis, candida infections, cytomegalo, others)
    • Development of malignant neoplasms (non-Hodgkin lymphoma and Kaposi sarcoma)

• A spectrum of HIV infections range from asymptomatic seropositivity to AIDS

• Urologic manifestations of HIV/AIDS:
  – Bacterial and nonbacterial infections
  – Voiding dysfunction
  – Renal impairment

EPIDEMIOLOGY
PREVALENCE
• 0.1% of US adults < 50 are infected
  – 2.6% of African American men and 1.5% of African American women were HIV positive from 1999 to 2006
  – 3.2 million people worldwide with HIV/AIDS
  – 2.1 million deaths due to HIV/AIDS in 2007

RISK FACTORS
• Unprotected intercourse, anal or oral sex
  – Fr drug abuse and needle sharing
  – Transmission of blood products
    – Consistent TID/ID
  – Uncircumcised phallus
  – Transmission of mother to infant at birth or via breast milk
  – Health care workers
    – Risk for HIV after percutaneous exposure to HIV-infected blood is 0.3%; after mucous membrane exposure 0.09%

GENETICS
• 3 groups of HIV viruses: M, N, and O
  – Most infections by class M
  – 9 subtypes of M exist
  – 15–20% genetic variation between viruses

PATHOPHYSIOLOGY
• HIV-1 infects cells expressing CD4, leading to decline in CD4 cells and immune function.
  – Immunosuppression allows opportunistic/sexual infections, demise; host defense against malignancy.

ASSOCIATED CONDITIONS
• UFT
  – Greater if CD4 count < 500/mm³
  – Associated with typical bacteria (Eubacterium coli, E. coli, enterococcus) and atypical pathogens such as fungi, mycobacteria, and viruses

• Epididymitis/orchitis
  – Chlamydia, gonorrhea, salmonella, toxoplasmosis

• Prostatectomy
  – Up to 16% in patients with AIDS
  – Greater risk in AIDS patients for developing postoperative abscess

• Urolithiasis
  – Risk with use of indinavir or from metabolic abnormalities

• Hepatitis B virus (HBV)
  – Malformations
    – Non-Hodgkin lymphoma
    – Usually B cell
    – May involve kidneys in 6–12% of AIDS patients
    – Kaposi sarcoma
    – Up to 20% of untreated patients
    – Testicular tumors
    – Usually seminoma
    – Up to 50% times more common
    – Renal cell carcinoma
    – Up to 8-fold increased risk vs. noninfected individual

• HIV associated nephropathy (HAN)
  – Prostatitis + > 3 g/d, edema, and HTN
  – Associated with focal segmental glomerulosclerosis (FSGS) on renal biopsy
  – Progression to dialysis in < 10 yrs.

• Voiding dysfunction
  – Can be retention, detrusor overactivity, and sphincter dyssynergia

GENERAL PREVENTION
• Barrier protection during sex (male and female condoms)
  – Mix well with any other HIV risk-reduction strategy
  – Available in 14 g/day

• Latex condoms
  – Can be retained, detrusor overactivity, and sphincter dyssynergia

• Screening HIV-1 antibody titers
  – If positive, need confirmation by Western blot or immunofluorescence.

• Need separate consent for HIV testing

• Lab
  – May show rectangular crystals from indinavir
  – Common bacterial pathogens in HIV-infected patients are E. coli, Enterobacter (enterococc), Pseudomonas aeruginosa, Proteus spp., Alcalivib, Acinetobacter, Staphylococcus aureus, group B streptococcus, Salmonella, and Salmonella spp.
  – If UTI suspected and C&S negative, consider atypical organisms: fungi, parasites, viruses

• U/Bladder stones
  – Specific testing for STD if urethral discharge present

IMAGING
• With flank pain: Noncontrast CT
  – Indium stones may not show on CT. Consider contrast study or intravenous pyelogram if renal impairment

• Social urinary tract infection
  – Prostatic abscess: CT scan

DIAGNOSIS
HISTORY
• Vaginal history (TTVA)
  – Dysuria
  – Frequency
  – Incontinence
  – Urinary discharge
  – Pelvic or testicular pain
  – Pain during
  – Proctologic history
  – Neurology
  – Gastroenterology
  – Social history
  – Sexual history

• IV drug use
  – Blood product transfusions

• Generalized symptoms: fever, weight loss, and chronic diarrhea are common symptoms.

• Review of systems (ROS): Constitutional symptoms, skin lesions, cough, oral ulceration

PHYSICAL EXAM
• General: Skin lesions, adenopathy
  – Neurologic exam: Numbness, alterations in sensation

• GU exam: Urethral discharge, testicular/penile/genital exam for masses, prostate exam for nodule or tenderness

• Perineal lesions of Kaposi sarcoma present as red/brown/purple nodules, macule, or papule
First Line

Highly active antiretroviral therapy (HAART)

– Combination therapy to combat the ability of HIV to generate drug-resistant mutants (DRMs)
– 10 million people now on antiretroviral therapy according to the WHO
– HAART therapy should be started in patients with:
  – AIDS
  – New WHO guidelines recommend starting therapy when CD4 count < 500/mm³ (previous guidelines were < 350/mm³)
– Pregnant women
– Patients with HIV nephropathy
– Confirmed with HIV regardless of CD4 count.

Second Line

– General urologic conditions such as UI, voiding symptoms, calcium stones treat as per general practice
– Salmonella epididymitis
– 2–4 wk of doxycycline 100 mg PO BID plus Cipro 500 mg PO BID
– If difficult to localize may need imaging suppression
– Kaposi sarcoma
– If focal, local radiation, cryosurgery, or radiotherapy
– For disseminated use chemotherapy (doxorubicin) or immunotherapy with interferons

SURGERY/OTHER PROCEDURES

– Indinavir and other protease inhibitor (PI) stones
  – Stop indinavir
  – Hydration
  – If necessary
  – Stones are soft and may pass after stenting.

ADDITIONAL TREATMENT

Radiation Therapy

Indicated in some cases of nodal Kaposi sarcoma

Additional Therapies

– For health care worker exposure
– Post-Exposure Prophylaxis (PEP)
  – Occupational PEP (OPEP): healthcare worker potentially exposed to material infected with HIV
  – Non-occupational PEP (NOPEP): someone is potentially exposed to HIV outside the workplace (eg, from sexual assault, unprotected sex, needle-sharing injection drug use)
  – begin within 72 hrs of exposure; 2–3 antiretroviral medications for 28 days

Pre-Exposure Prophylaxis (PrEP)

– For people who are HIV-negative and at substantial risk for HIV infection (relationship with HIV-infected partner, gay or bisexual man who has had sex without a condom or been diagnosed with a sexually transmitted infection within the past six months, others
– Along with other prevention methods like condoms, PrEP can offer good protection against HIV.

COMPLICATIONS

– Antiretroviral therapy
  – Risk of nephrotoxicity, crystal precipitation leading to stones, hypocalcemia
  – Erectile dysfunction and decreased libido (caused by increased estradiol) may be associated with HAART therapy

– Drugs used for the treatment of HIV-infected patients have become the most frequent cause of drug-containing urinary calculi.

– Among these agents, PI’s are well known to induce kidney stones, (indinavir, atazanavir, darunavir).

FOLLOW-UP

– CD4 counts
– Serum creatinine

Patient Monitoring

– CD4 counts

HOT FLUSHES/VASOMOTOR INSTABILITY IN MALES

Tara K. Ortiz, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Hot flushes are typically described as a feeling of intense heat with associated flushing, sweating, rapid heart rate, and anxiety.
- Sometimes called “hot flashes”.
- Common side effect of androgen ablation therapy in men with metastatic or locally advanced prostate cancer.
- Flushing can be associated with wide ranges of other conditions and medications.
- This section primarily discusses this condition in males.

EPIDEMIOLOGY

Incidence

- Occurs in 50–80% of men on androgen deprivation therapy.

Incidence

- Prevalence

TREATMENT

GENERAL MEASURES

- Reassure if symptoms mild.
- Attempt to identify and avoid lifestyle triggers.
- Keep environment cool.
- Ask about use of dosed acetaminophen, aspirin, or ibuprofen.
- Avoid tobacco, alcohol, and caffeine.
- Avoid hot baths or showers.
- Keep cool, dry bedding.

DIAGNOSIS

HISTORY

- Abrupt onset of warmth, frequently followed by profuse sweating requiring change of clothes.
- More likely to occur at night.
- Sensation typically affects the face and trunk.
- Duration is typically seen within the 1st yr after androgen ablation.
- Onset is typically seen within the 1st yr after androgen ablation.
- Episodes may be daily or occur intermittently.

PHYSICAL EXAM

- Rapid heart rate, and anxiety
- Profuse sweating
- Slight increase in oral and forehead temperature
- Perspiring frequently present
- During acute episode, facial flushing common

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No routine lab evaluation indicated.
- No pattern of characteristic changes in testosterone, follicle-stimulating hormone (FSH), or prolactin

Imaging

- No Imaging

Diagnostic Procedures/Surgery

- No Pathologic Findings

ASSOCIATED CONDITIONS

- Cholinergic syndrome
- Ectopic, parasympathetic reflexes
- Metabolic syndrome (insulin resistance, unfavorable lipid profile, increased fat mass)
- Gynecomastia
- Hormonal, normochromic anemia
- Fatigue

DIFFERENTIAL DIAGNOSIS

- Hypesthesia or hypohidrosis
- Emotional blushing
- Systemic illness:
- Cerebral syndrome
- Rheumatoid arthritis
- Metastatic thyroid tumors
- Paracrine/somatostatinomas
- Benign prostatic hyperplasia
- Ovarian disease
- Neurologic disorders
- Medications:
- Phosphodiesterase 5 inhibitors (sildenafil, tadalafil, avanafil)
- Any vasodilator agent (nitroglycerine, etc.)
- Nicotinic acid
- Calcium channel blockers most commonly nifedipine, diltiazem, amlodipine
- Opoids
- Antidepressants
- Antibiotics (saxopenycin, amphotericin B)
- Nonsteroidal anti-inflammatories
- Dietary
- Ethanol ingestion
- Monosodium glutamate or other food additives

TREATMENT

GENERAL MEASURES

- For flushing related to androgen deprivation therapy:

SYSTEMIC

- Antihypertensives (β-blockers, angiotensin-converting enzyme inhibitors, diuretics)
- Antidiabetics
- Antihistamines
- Antidepressants
- Antipsychotics
- Anticonvulsants
- Antithyroid medications
- Antiepileptics
- Anticoagulants
- Antibiotics (saxopenycin, amphotericin B)
- Nonsteroidal anti-inflammatories
- Dietary
- Ethanol ingestion
- Monosodium glutamate or other food additives

MEDITATION

First Line

- For androgen deprivation therapy related hot flushes most are hormonal agents:

- Megestrol acetate (Mepron 20 mg/d)
- Synthetic derivative of progesterone
- – 1 study demonstrated complete resolution of symptoms in 90% of patients, >90% improvement in 25% (10,38)
- Side effects include: weight gain, nausea, androgen/progesterone blockade

- Nifedipine, nisoldipine, amlodipine
- Calcium channel blockers most commonly nifedipine, diltiazem, amlodipine

- Nicotinic acid
- Any vasodilatory agent (nitroglycerine, etc.)
- Phosphodiesterase 5 inhibitors (sildenafil, tadalafil, avanafil)
- Rosacea
- Renal cell carcinoma
- Pancreatic islet cell tumors
- Medullary thyroid tumors
- Pheochromocytoma
- Carcinoid syndrome

- Monosodium glutamate or other food additives
- Nonsteroidal anti-inflammatories

DIFFERENTIAL DIAGNOSIS

- N/A
- Pathologic Findings

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No routine lab evaluation indicated.
- No pattern of characteristic changes in testosterone, follicle-stimulating hormone (FSH), or prolactin

Imaging

- No Imaging

Diagnostic Procedures/Surgery

- No Pathologic Findings

ASSOCIATED CONDITIONS

- Cholinergic syndrome
- Ectopic, parasympathetic reflexes
- Metabolic syndrome (insulin resistance, unfavorable lipid profile, increased fat mass)
- Gynecomastia
- Hormonal, normochromic anemia
- Fatigue

DIFFERENTIAL DIAGNOSIS

- Hypesthesia or hypohidrosis
- Emotional blushing
- Systemic illness:
- Cerebral syndrome
- Rheumatoid arthritis
- Metastatic thyroid tumors
- Paracrine/somatostatinomas
- Benign prostatic hyperplasia
- Ovarian disease
- Neurologic disorders
- Medications:
- Phosphodiesterase 5 inhibitors (sildenafil, tadalafil, avanafil)
- Any vasodilator agent (nitroglycerine, etc.)
- Nicotinic acid
- Calcium channel blockers most commonly nifedipine, diltiazem, amlodipine
- Opoids
- Antidepressants
- Antibiotics (saxopenycin, amphotericin B)
- Ni...
HOT FLUSHES/VASOMOTOR INSTABILITY IN MALES

• Denolad/hydrocortisone (DS): 0.1–1 mg/d:
  – 20–40% of men achieve excellent results [1]
  – Side effects include painless gynecomastia
  – At low doses, thromboembolic events are not a significant problem.
  – Generic drug, expensive though difficult to obtain in US

• Cyproterone Acetate (Androcur) 100 mg/d
  – Not approved for use in US
  – Peripheral antagonism, antigonadotropin with progestin-like activity
  – May interfere with ADT regimen
  – A study demonstrated resolution of symptoms in 84% of patients, 50% improvement in 37% (CBE)
  – Side effects include fatigue, increased risk of thrombosis, amenorrhea, potential hepatotoxicity, gynecomastia

Second Line (Nonhormonal Therapy)

• Venlafaxine (Effexor) 150–375 mg/d:
  – Antidepressant of the serotonin-norepinephrine reuptake inhibitor (SNRI) type
  – Median weekly hot flush scores decreased 54% from baseline after 1 mo (CBE)
  – Side effects include lack of sexual desire, delayed orgasm, and increase in suicidal ideation

• Paroxetine (Paxil-CR) 12.5–37.5 mg/d:
  – Antidepressant of the selective serotonin reuptake inhibitor (SSRI) class
  – In 1 study, daily hot flushes decreased from 6.2–2.5 (BHR)
  – Side effects include sexual dysfunction, constipation

• Ergotamine/baclofen/phenobarbital (EBP): 1 tablet PO BID:
  – Ergot used primarily to treat migraine headaches
  – Use with caution in patients with monosymptomatic headache disorders (MID), central nervous system (CNS) depressants, anticholinergic agents
  – Generally not recommended for the treatment of hot flashes in men

• Gabapentin (Neurontin) 900 mg/d (300 mg BID or TID):
  – Anticonvulsant treatment of neuropathic pain
  – Mosted 46% reduction in hot flush symptom score at target dose of 900 mg
  – Side effects include nausea, somnolence, dizziness, and constipation

• Clonidine (Catapres) 0.1–1 mg/d (PO or patch formulations):
  – Generally well tolerated with less of a fall in blood pressure
  – 13 of men will report a partial response although similar to placebo (13B)
  – Side effects include hypotension, dry mouth, skin irritation from patches

SURGERY/OTHER PROCEDURES

ADDITIONAL TREATMENT Radiation Therapy

Additional Therapies

• Acupuncture:
  – 1–2 wk twice weekly × 2 wk then once weekly × 8–10 wk
  – 43–78% reduction in frequency of flushes, average 9 mo duration of effect [13B]

• Vitamin E:
  – 30% reduction in 22% of women receiving placebo in 1 study (not studied in men)
  – May increase the risk of prostate cancer; unclear effect on existing cancer (10B)

• Soy products:
  – Contains phytoestrogens which might decrease severity of hot flushes (11C)
  – Also shown benefit with regard to cardiac and bone health
  – Black cohosh
  – Has been used in some postmenopausal women for treatment of hot flushes
  – Mechanism is unknown
  – In 1 trial, no difference found with men taking placebo (11C)

ONGOING CARE

PROGNOSIS

• Most men have symptom improvement with medical or complementary therapy
• 4–6 yr of treatment with ADT over 40% of men still have flushes
• In 1 study, 72% of patients noted that hot flashes interfered with sleep and 59% reported they interfered with the quality of life

COMPLICATIONS

Some men have side effects from medications taken to alleviate hot flushes (bloating, weight gain, rash, gynecomastia)

FOLLOW-UP

Patient Monitoring

• Ask patients on androgen deprivation therapy at each follow-up clinical evaluation about the presence and severity of hot flushes
• Requires a substantial side effect from therapy
• Immediate cessation of treatment can be used if side effects become bothersome
• May have positive effect on quality of life, but may decrease survival

Patient Resources

N/A

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)

• Andropause (Sex Hormone Hypothesis)
• Menopause, Urogynecologic Considerations
• Testosterone, Decreased (Hypogonadism)

CODES

ICD9

• 189.2 Syncope and collapse
• 780.8 Generalized hyperhidrosis
• 793.62 Flushing

ICD10

• B82.3.2 Flushing
• S83 Syncope and collapse
• R81.1 Generalized hyperhidrosis

CLINICAL/SURGICAL PEARLS

• Symptoms are usually reversible with cessation of ADT usually within 3–4 mo of stopping treatment.
• Most effective treatment is hormonal therapy with estrogen or progesterone derivatives
• There are limited data to support alternative/complementary therapies.
HYDROCELE, ADULT & PEDIATRIC
Costas D. Lallas, MD, FACS
Leonard G. Gomella, MD, FACS

DESCRIPTION
A hydrocele is a collection of serous fluid in some part of the processus vaginalis, usually in the tunica vaginalis. Can be congenital or acquired.

PATHOPHYSIOLOGY

ASSOCIATED CONDITIONS

ASSOCIATED CONDITIONS

PHYSICAL EXAM

Acquired: Can be primary or acquired secondary to disease of the testis. Secondary hydroceles may present acutely or chronically.
• The hydrocele of the canal of Nuck is comparable in infants/children to the hydrocele of the spermatic cord in adults.
• Changes in size of the swelling (eg, size varies throughout day).

DIAGNOSTIC TESTS & INTERPRETATION

DIFFERENTIAL DIAGNOSIS
• Cord lipoma
• Epididymo-orchitis
• Hydrocele of the spermatic cord
• Inguinal hernia
• Lymphedema of the external genitalia
• Neoplasms

PHYSICAL EXAM

• Transillumination test:
  – If transilluminates, favors simple hydrocele, but is not diagnostic.

RISK FACTORS

Lab

DIAGNOSIS

HISTORY

BASICS

No racial predilection

1% of adult males; prevalence: 1,000 in 100,000

• Prematurity, low birth weight are risk factors

GENETICS

• Hydrocele fluid characteristics:
  – Amber colored; specific gravity of 1.022–1.024
  – Components: water, inorganic salts, 6% albumin, and fibrinogen
  – Nonclotting, unless a drop of blood added
  – Chronic hydrocele: cholesterol-rich
  – Occasionally, tyrosine crystals are present

PREVALENCE

• No social prediction

PREVALENCE

• Migration of ventriculoperitoneal (VP) shunt
• Trauma with bleeding (technically a hematocele)
• Defective absorption of fluid by tunica vaginalis; known as congenital hydrocele
• Components: water, inorganic salts, 6% albumin, and fibrinogen
• Hydrocele of the canal of Nuck
• Hydrocele of the spermatic cord

DIAGNOSTIC TESTS & INTERPRETATION

– Hydrocele of the cord (PPV patent with obliteration of the peritoneal cavity)
– Congenital communicating (PPV communicates through the peritoneal cavity)
– Infantile (PPV around testis and cord)
– Exstrophy of the bladder
– Ehlers–Danlos syndrome
– Anasarca (protein-loosing enteropathy, cirrhosis)
– Nephrotic syndrome
– Retroperitoneal process with obstruction of the lymphatics (ie, multiple lymphatic filariasis)
– Nephritic syndrome
– Acartia (protein-losing enteropathy, cirrhosis)
– Spermatocele
TREATMENT

GENERAL MEASURES
- Adults:
  - No treatment is necessary unless the hydrocele causes discomfort or cosmetic concerns or there is a significant underlying cause present, such as a tumor.
  - Communicating hydroceles in older patients may have increased risk of incarceration.
- Children:
  - Most will resolve in 1st yr of life.
  - For newborns and children < 1 yr supportive care is indicated.
  - Persistence beyond age 1 suggests the presence of a patent indirect hernia sac that should be repaired.

MEDICATION

GENERAL MEASURES
- Adults: - Scrotal approach with drainage of the hydrocele
- In hydrocele of the cord, the sac can be completely closed
- High ligation of the processus vaginalis and division of the internal spermatic vessels
- Inguinal incision between internal and external spermatic vessels
- Persiste beyond age 1
- Children: - Persistence beyond age 1
- Suggests the presence of a patent indirect hernia sac that should be repaired.

COMPLEMENTARY & ALTERNATIVE THERAPIES
- Scrotal support may provide relief of discomfort.

ONGOING CARE

PROGNOSIS
- Many hydroceles do not enlarge and can be observed if confirmed that there is no underlying pathology.
- Follow-up (based on ultrasound confirmation).

COMPLICATIONS
- Rupture: Usually traumatic
- Nausea, vomiting, abdominal pain associated with damage to vascular supply to the testicle
- Postoperative:
  - Testicular atrophy or infarction after repair due to damage to vascular supply to the testicle
  - Recurrence

FOLLOW-UP

Patient Monitoring
- Periodic follow-up (baseline US) suggested if managed by observation; return for any change in symptoms.
- Patients of a resection with a hydrocele should be instructed in the natural history of the condition in children.
- Following surgical repair, edema may take several weeks to resolve.

ADDITIONAL TREATMENT

Radiation Therapy
N/A

ADDITIONAL THERAPIES
- Aspiration of the hydrocele, with or without the injection of sclerosing agents is not usually recommended.
- Noninfected hydrocele aspiration and sclerotherapy with doxycycline has been reported to have an 84% success rate with a single treatment.
- Aspiration may have a role in postoperative hydroceles such as after inguinal hernia repair.

REFERENCES

ADDITIONAL READING

- Canal of Nuck Hydrocele and Cyst (Female Hydrocele)
- Groin/Inguinal Mass, Male and Female
- HIV/AIDS, Urologic Considerations
- Image 9
- Hydrocele of the Spermatic Cord
- Spermatocele

CODES

ICD9
- 603.8 Other specified types of hydrocele
- 603.9 Hydrocele, unspecified
- 778.6 Congenital hydrocele

ICD10
- N43.2 Other hydrocele
- N43.3 Hydrocele, unspecified
- P83.5 Congenital hydrocele

CLINICAL/SURGICAL PEARLS
- Tenderness, fever, or other symptoms such as nausea, vomiting, abdominal pain associated with an acute hydrocele requires immediate evaluation to rule out other scrotal pathology.
- The inability to transilluminate a hydrocele could be due to a thick-walled or septated hydrocele, another cause of an enlarged scrotum such as tumor or hematoma or the presence of bowel in a large hemia defect.
HYDROCOLPOS AND HYDROMETROCOLPOS, PEDIATRIC
Sarah M. Lambert, MD
Pasquale Casale, MD, FACS

BASICS
DESCRIPTION
Hydrocolpos and hydrometrocolpos are congenital anomalies of the female reproductive tract due to an imperforate hymen or less commonly due to a transverse vaginal septum.
– Hydrocolpos: Gross distension of the vagina with fluid
– Hydrometrocolpos: Gross distension of vagina and uterus with fluid. May also be associated with vaginal or cervical atresia, stenosis, ureteral anomalies, or cloacal anomalies
– Hematocolpos: bloody fluid in vagina
– Hematometrocolpos: bloody fluid in vagina and uterus
– May be an infrequent cause of an abdominal mass in a newborn female

EPIDEMIOLOGY
Incidence
0.1–3.8% of live female births
Prevalence
N/A

RISK FACTORS
– Imperforate hymen
– High/low transverse vaginal septum
– Urogenital sinus/cloacal abnormality

Genetics (1)
– McKusick–Kaufman syndrome
  – Autosomal recessive multiple malformation syndrome
  – Characterized by vaginal atresia with hydrometrocolpos, polydactyly, congenital heart defects, nonimmune hydrops fetalis
– Bardet–Biedl syndrome
– Langer–Giedion syndrome
– Herlyn-Werner-Wunderlich (HWW) syndrome

PATHOPHYSIOLOGY
– Hydrocolpos: Congenital obstruction of the female genital tract leading to accumulation of vaginal secretions and distension of the vagina
– Hydrometrocolpos: Same as hydrocolpos but the pressure now is transmitted past the cervix into the uterus causing distention of both vagina and uterus.
– The most frequent cause of hydrometrocolpos is the presence of imperforate hymen due to failure of partial resorption of this membrane during the embryonic development
– Hymen fails to rupture during the 8th wk of gestation

ASSOCIATED CONDITIONS
– Vaginal atresia
– Urogenital anomalies
– Ureteral anomalies
– Other malformations, such as imperforate anus, bilateral cleft lips, polydactyly, oligo-or anhydrotic ectodermal dysplasia
– Pediatric considerations:
  – The diagnosis should be considered in the pubertal female with amenorrhea

GENERAL PREVENTION
Early diagnosis may prevent urinary retention, hydronephrosis, and upper urinary tract complications.

DIAGNOSIS
HISTORY
– Sonolucent mass on prenatal ultrasound (US)
– Stranguria due to bladder outlet obstruction
– Intestinal obstruction with larger mass
– Amenorrhea in pubertal females if the problem was not diagnosed before menarche. In these rare cases, chronic cyclic lower abdominal pain may be present.

PHYSICAL EXAM
– Imperforate hymen with bulging cystic vaginal introitus. The hue is typically bluish if there is trapped blood.
– Palpable suprapubic mass due to distended bladder if associated with outlet obstruction
– Lower extremity lymphedema due to decreased venous return
– Examine for stigmata of McKusick–Kaufman syndrome (see above)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
– Electrolytes and creatinine if significant bilateral upper urinary tract dilation

Imaging
– Abdominal US:
  – Large constant cystic mass displacing bladder anteriorly and rectum posteriorly
  – May see layering of fluid
  – Hydronephrosis or ureteral ectasia may be present
– Prenatal sonogram can detect hydrocolpos as an antenatal diagnosis but usually cannot identify the etiology
  – IVU:
    – May see hydroureteronephrosis and a distended bladder
  – VCUG:
    – May see an anterolaterally displaced bladder
  – MRS/MRU:
    – May be useful for further delineation of pelvic anatomy when US is equivocal

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS (2)
– Dermoid cyst
– Hydrometrocolpos:
  – Accumulation of menstrual blood products in vaginal and uterine cavity
– Mucocolpos
– Ovarian cyst
– Periurethral cyst:
  – Eccentric smooth mass displacing urethral meatus
– Prolapsed ureterocele:
  – May see necrotic tissue, asymmetric urethral meatus
– Prolapsed urethra:
  – Donut-shaped urethral meatus in the center of a normal vaginal introitus
– Rhabdomyosarcoma:
  – Cluster of grapelike masses protruding from vaginal introitus
TREATMENT

GENERAL MEASURES (2)
- Incision of the hymen if due to imperforate hymen. If an imperforate hymen is present and no mass or hydronephrosis is present, surgical correction is sometimes delayed until tissues become more estrogenized. However, the correction of the imperforate hymen must take place before there is development of hydrocolpos.
- Address vaginal or cervical issues as the anatomic pathology presents

MEDICATION
First Line
N/A
Second Line
N/A

SURGERY/OTHER PROCEDURES
- Simple incision of the imperforated hymen. A cruciate incision with resection of excess tissue tags as necessary
- Cloacal anomalies require a coordinated surgical team and planned intervention.
- Vaginal septum if present needs to be incised either endoscopically or through open surgery

ADDITIONAL TREATMENT
Radiation Therapy
N/A
Additional Therapies
N/A
Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Excellent, especially with early diagnosis and treatment

COMPLICATIONS
- Renal compromise or acute kidney injury with severe hydronephrosis
- Abdominal ascites
- Urinary retention and voiding difficulty
- Reports of increasing rates of infertility based upon level of obstruction
- Respiratory compromise in neonates due to massive abdominal distension
- At menarche, retrograde flow may predispose patient to endometriosis

FOLLOW-UP
Patient Monitoring
Usually none necessary. Follow for resolution of hydronephrosis if present.
Patient Resources
N/A

- Q52.11 Transverse vaginal septum

CLINICAL/SURGICAL PEARLS
The diagnosis should be considered in the pubertal female with amenorrhea.
HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), ADULT
Kelly A. Healy, MD
Demetrios H. Bagley, MD, FACS

BASICS

DESCRIPTION
- Hydronephrosis includes dilation of the renal pelvis and calyces while hydroureteronephrosis is dilation of the renal pelvis, calyces, and ureter.
- Both can result from obstructive and nonobstructive causes.
- Intrinsic and extrinsic obstructive processes can affect the entire urinary tract.

EPIEDEMOLOGY

Incidence
- Asymptomatic unilateral hydronephrosis occurs in ~3% of population.
- Prevalence
  - 3.1% prevalence in historic autopsy series of 59,000 patients
  - Age 20–40 more common in women, secondary to pregnancy/gynecologic conditions
  - Age >40 prostate obstruction more common in men
  - A similar 2.5% prevalence of asymptomatic unilateral hydronephrosis in radiologic series among potential renal donors
  - No association with potential donor age

Prevalence
- 60 yr obstruction more common in men

RISK FACTORS
- Unilateral is most common cause of upper urinary tract obstruction, prevalence between 10–15% by age 70 yr
- Ureteropelvic junction (UPJ) obstruction can occur from anatomic crossing vessel, high insertion, or secondary conditions (implanted stone)
- Lower urinary tract disorders can result in hydronephrosis, often bilateral
- Benign prostatic enlargement is the most common affecting 70% of men by age 70
- Hydronephrosis can develop with obstructive lesions at essentially any level.
- Kidney
  - Benign lesions including peripelvic cysts
  - Malpant neoplasms with renal cell carcinoma and urethelial carcinoma
  - Renal pelvic calculus
  - UPJ obstruction
  - Infection tuberculosis
  - Renal artery aneurysm
  - Hilar lymphadenopathy
- Ureter
  - Neoplasms: Benign papilloma, fibroepithelial polyp, ureteric strictures, malignant urethral carcinoma
  - Urinary calculi or stricture
  - Ureteroceles or congenital megoureter
  - Infection (tuberculosis, schistosomiasis)
  - Retroperitoneal lymphadenopathy (lymphoma, other malignancy)
  - Inflammation (nephropathy fibrosis and arterial aneurysms)
  - Genitourinary: Ovarian vein syndrome, endometriosis, GYN malignancy, pregnancy
  - Pelvic lymph node
  - Retrocaval ureter
  - Bladder diverticula
  - Müllerian neoplasms: eg, urethelial carcinoma
  - Locally advanced carcinoma of the prostate
  - Bladder neck contracture
  - Prune bellie syndrome
  - Detrusor dysfunction
  - Intravenous hypertension
  - Urinary tract infection, renal parenchymal disease

GENETICS
- Nonobstructive hydronephrosis occurs with several congenital syndromes, usually diagnosed in infancy (see “Hydronephrosis/Hydroureteronephrosis, Pediatric”).

PATHOPHYSIOLOGY

- Effective hydronephrosis on renal function depends on whether it is totally or partially obstructive and unilateral or bilateral.
- Effects of obstruction of the kidney are time dependent.
- Within several hours, changes are evident but (1) 1–2 wk—glomerular destruction, tubular atrophy, and interstitial fibrosis occur
- By 6–8 wk irreversible damage occurs

ASSOCIATED CONDITIONS
- Numerous causal conditions can be associated. See “Risk Factors” above.
- Acute obstruction can cause abdominal flank pain and/or back pain; may be associated with anemia, nausea, vomiting
- Gradual unilateral obstruction more typically presents with vague complaints or may be asymptomatic
- Acute obstruction of solitary kidney or bilateral can present with symptomatic obstructive uropathy or evidence of renal compromise
- Complete urinary history is essential
- Site of obstruction, upper vs. lower urinary tract may relate to presentation
- Upper urinary tract—back pain, costovertebral angle tenderness with acute obstruction
- Lower urinary tract maybe associated with obstructive voiding symptoms

PHYSICAL EXAM
- General condition—pain or localized symptoms
- Hypertension can be related to obstruction
- Abdominal, flank, or pelvic mass
- Reflex tenderness at site of obstruction
- No association with potential donor age
- Ureteral palpation
- Ureterocoele through urethra
- Digtal rectal exam
- Enlarged prostate, nodularity suggestive of prostate cancer

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis for hematuria, pyuria, crystalluria
- Urine culture
- Renal function studies:
  - BUN & creatinine
  - Serum prostatic-specific antigen (PSA)

CBC
- Anemia—associated with chronic renal insufficiency
- Elevated white blood cell count with infection

Imaging
- Several modalities are available. They differ in their degree of anatomic and functional information and may determine the presence and extent of obstruction.
- Renal ultrasound: inexpensive, widely available, no ionizing radiation, and no contrast
- Should include imaging through the bladder to assess for distal hydronephrosis, ureteral jets, bladder wall thickening, and postvoid residual
- Renal scans can be evaluated
- Color Doppler renal ultrasound
- Help distinguish obstructive vs. nonobstructive hydronephrosis

DIAGNOSIS

HISTORY
- Signs and symptoms vary dependent on the etiology and chronicity of the condition
- Acute obstruction can cause abdominal flank and/or back pain; may be associated with anemia, nausea, vomiting
- General and acute obstruction more typically presents with vague complaints or may be asymptomatic
- Acute obstruction of solitary kidney or bilateral can present with symptomatic obstructive uropathy or evidence of renal compromise
- Complete urinary history is essential
DIFFERENTIAL DIAGNOSIS

Pathologic Findings

- Chronic pyelonephritis
- Renal tuberculosis
- Tuberculosis (see above)

DIFFERENTIAL DIAGNOSIS

- Obstructive or nonobstructive hydronephrosis
- See also “Risk Factors”

TREATMENT

GENERAL MEASURES

- Management is highly dependent on underlying condition and the timing (acute vs. chronic)
- Urgent decompression is needed with:
  - Severe pain
  - Active urinary tract infection and acute kidney insufficiency
  - Retrograde ureteral or percutaneous nephrostomy can provide equally effective drainage
- Hydronephrosis lower urinary tract etiology is typically bilateral and patients may be asymptomatic
- May warrant catheter drainage or endoscopic treatment

MEDICATION

First Line

- Patients with infection and hydronephrosis require antibiotic therapy and drainage
- Renal failure and electrolyte abnormalities should be corrected in conjunction with drainage

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Catheter drainage of obstructed system with percutaneous nephrostomy or ureteral stent is required
- Hydronephrosis and fever may be ominous signs requiring early drainage
- Other surgical procedures can be guided by the findings on imaging studies

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Course varies

COMPLICATIONS

- Renal failure
- Re-infection
- Stricture formation
- Ureteral stricture
- Bilateral hydronephrosis

FOLLOW-UP

Patient Monitoring

- The timing for hydronephrosis will determine the appropriate surveilance regimen
- Consider renal ultrasound and renal scan at 3 mo after treatment
- Postoperative imaging may demonstrate the dilatation persists despite relief of obstruction

Patient Resources

CODES

ICD9

- 591 Hydronephrosis
- 600.00 Hypertrophy (benign) of prostate without urinary obstruction
- 601 Hydronephrosis

ICD10

- N13.2 Hydronephrosis with renal and ureteral calculous obstruction
- N40.0 Enlarged prostate without lower urinary tract symptoms
- N03.0 Hypertrophy (benign) of prostate with urinary obstruction and other lower urinary tract symptoms (LUTS)

CLINICAL/SURGICAL PEARLS

- Hydronephrosis and fever especially sepsis may require immediate drainage.
- Hydronephrosis may be nonobstructive.
- Generally hydronephrosis in an adult can be considered a sign of a process that must be defined and possible treated.
**HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PEDIATRIC**

Ahmad H. Bani-Hani, MD, FAAP, FACS

---

### BASICS

#### DESCRIPTION
- Refers to dilation of any part of the collecting system, single or combined:
  - Pelvic (renal pelvis)
  - Calyceal (calyces)
  - Pyeloureteral (both renal pelvis and calyces)
  - Ureteral (ureter)
  - Hydroureteronephrosis (ureter-collecting system is dilated)
- Society of Fetal Urology (SFU) grading of infant hydronephrosis (1991)

#### EPIDEMIOLOGY
- Prenatal hydronephrosis is detected in about 1.4% of total prenatal ultrasound performed in US.
- The true incidence is difficult to determine secondary to many asymptomatic, undetected cases.

#### RISK FACTORS
- Family history of hydronephrosis, maternal type I diabetes mellitus (associated with infant sacral agenesis)
- Genetic syndromes: Downs, trisomy 13, trisomy 18, CHARGE, Ehlers–Danlos, Menkes, Prune belly, etc.
- Horseshoe kidney/pelvic kidney
- Duplication renal anomalies
- Neurogenic bladder secondary to tethered spinal cord, myelodysplasia, sacral agenesis

#### GENETICS
- No specific genetic abnormalities except if associated with specific genetic syndromes as outlined above.

#### ALERT
- Hydronephrosis is not a specific diagnosis but a finding or sign. The cause of the hydronephrosis is the diagnosis and indicates the appropriate treatment.

### PATHOPHYSIOLOGY
- **Physiologic hydronephrosis**: Unclear etiology but typically improves with serial renal ultrasound monitoring
- **Pathologic hydronephrosis**:
  - Vesicoureteral reflux: Reflux can be primary or secondary to conditions that raise the intravesical pressures (e.g., bladder outlet obstruction and neurogenic bladder)
  - Ureteropelvic junction (UPJ) obstruction (1991):
    - Defined as obstruction to the flow of urine from the renal pelvis to the proximal ureter
    - Considered to be the commonest cause of prenatal hydronephrosis
    - Obstruction can be caused by an intrinsic narrowing at the UPJ or by an extrinsic compression by a lower pole anteriorly crossing vessel
    - Examples of intrinsic obstruction can include: Narrow segment with musculomembranous obstruction, ureteral valves, musculature, fibrosis
  - Ureteral valves:
    - Primary: Called primary obstructive megareter.
    - The most common finding is a distal adenogenic ureteral segment that affects the flow of urine resulting in a functional obstruction
    - Secondary: Distal stone, hypertrophy of the distal ureter and trigone in neurogenic bladder or posterior urethral valves
    - Ureterocele:
      - Defines as cystic dilation of the distal ureteral segment
      - More common in females and can cause obstruction to the distal ureter flow
      - Often associated with duplication anomalies of the kidney, particularly involving the upper pole moiety
- Ectopic ureter:
  - Occurs when the distal opening of the ureter is not in the normal location at the urethro-trigonal junction
  - Ureter can enter the bladder neck, urethra, and, in females, the vestibule, vagina, and rarely the uterine cavity
  - Ectopic ureters opening outside the bladder or urethra tend to be obstructed and often associated with nonfunctioning renal moiety
  - Commonly involves the upper pole moiety in duplicated renal anomalies
  - Posterior urethral valves:
    - The most common cause of congenital lower urinary tract obstruction in males (1/4,000 to 1/7,500 births)
    - Values in severity and can result in deterioration of renal function, and progressive oligohydramnios, which may lead to pulmonary hypoplasia with a high risk of perinatal mortality and mortality
    - Other causes:
      - Abnormal urethral valves
      - Urethral atresia
      - Neurogenic neurogenic bladder (Hirman syndrome)

### ASSOCIATED CONDITIONS
- Hydronephrosis can be by physiologic or pathologic associated with many condition as noted above.

### DIAGNOSIS

#### HISTORY
- Detailed prenatal history of:
  - Timing of 1st detection of hydronephrosis in relation to gestational age
  - Ultrasound vs. bilateral
  - Gender of the baby
  - Maternal diabetes mellitus, particularly type I (associated with fetal sacral agenesis)
  - Family history of renal anomalies
  - Amniotic fluid volume
  - Prenatal allergy to penicillin
  - Detailed postnatal history:
    - Circumcision status
    - Birth weight
    - Jaundice
    - Urinary tract infections
    - Incontinence
    - Hypertension, failure to thrive

#### PHYSICAL EXAM
- Vital signs, particularly blood pressure
- Weight
- Jaundice
- Abdominal masses
- Is bladder palpable?
- Genital/anorectal exam
- Cutaneous manifestations of spina bifida occulta
- Is bladder palpable?
- Jaundice
- Birth weight
- Circumcision status
- Paternal allergy to penicillin
- Amniotic fluid volume
- Family history of renal anomalies
- Gender of the baby
- Unilateral vs. bilateral

#### DIAGNOSTIC TESTS & INTERPRETATION

**Lab**
- Basic metabolic panel
- Urine analysis and culture if indicated

**Imaging**
- Renal and bladder ultrasound (RUS)
- Should be 1st-line imaging study
- Will give excellent idea about the laterality and severity of hydronephrosis, associated bladder pathology such as ureteroceles, are ureters dilated too?
- Bladder pathology such as abnormal bladder wall thickness, key hole sign in posterior urethral valves
- Indirect way to assess overall renal function by looking at echogenicity and thickness of renal parenchyma

#### DIAGNOSIS
- Imaging
  - Renal and bladder ultrasound (RUS)
  - Should be 1st-line imaging study
  - Will give excellent idea about the laterality and severity of hydronephrosis, associated bladder pathology such as ureteroceles, are ureters dilated too?
  - Bladder pathology such as abnormal bladder wall thickness, key hole sign in posterior urethral valves
  - Indirect way to assess overall renal function by looking at echogenicity and thickness of renal parenchyma

      - Neurogenic neurogenic bladder (Hirman syndrome)
HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PEDIATRIC

**MEDICATION**

- **Anticholinergic drugs** in cases of an overactive bladder
- **β-blockers** in some cases of bladder outlet obstruction
- **β-Blockers in some cases of bladder outlet obstruction**

**DIAGNOSIS**

- **Cystoscopy and retrograde pyelogram** can be used to define the anatomy of the collecting system and placement of a drainage stent
- **Diuretic renal scan** (MAG-3 with Lasix): – Can provide useful information such as renal function and anatomic details when evaluating conditions such as ectopic ureter location
- **Voiding cystourethrogram**: – Can provide useful information such as renal function and anatomic details when evaluating conditions such as ectopic ureter location

**DIFFERENTIAL DIAGNOSIS**

- **Renal cysts**
- **Polycystic renal disease**
- **Multicystic dysplastic kidney**
- **Prominent extrarenal pelvis**

**ADDITIONAL TREATMENT**

**Radiation Therapy**

- **Additional Therapies**: – **Clean intermittent catheterization** in cases of hydronephrosis and/or presence of reflux

**COMPLICATIONS**

- **Urinary incontinence**
- **Renal scarring**
- **Renal insufficiency**
- **Reflux**
- **Multiple UTIs**
- **Kidney/bladder stones**
- **Hypertension**

**FOLLOW-UP**

- **Patient Monitoring**: – **Patient need meticulous follow-up once hydronephrosis is diagnosed before and after treatment**

**TREATMENT**

- **Referral to pediatric urology/nephrology** for full assessment and treatment

HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PRENATAL

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

BASICS
DESCRIPTION
- May represent a normal developmental variant or a pathologic anomaly.
- Prenatal hydronephrosis (PH) may be observed early in pregnancy but the diagnosis usually cannot be made with certainty until 16 wk of gestation.
- Severe PH has a higher incidence of associated anomalies.
- Genetic counseling is recommended for all parents of a child with PH.

ASSOCIATED CONDITIONS
Congenital hydronephrosis is associated with many syndromes.

GENERAL PREVENTION
None.

DIAGNOSIS
HISTORY
- Timing of prenatal detection; earlier detection implies more severe condition.
- Presence of polyhydramnios and renal cortical thinning indicate more severe condition.
- Presence of cortical cysts may indicate dysplasia.
- Unilateral vs. bilateral renal involvement is a critical determination for diagnosis and prognosis.
- Change in dilation in relation to bladder filling may indicate vesicoureteral reflux.
- Presence of oligohydramnios important: Suggests severe renal function.
- Associated with severe obstructive pathology due to PUVs, congenital urethral stricture, or ureterocele obstructing bladder outlet.
- Associated with pulmonary hypoplasia and fetal or neonatal death.

PHYSICAL EXAM
- None.

DIAGNOSTIC TESTS & INTERPRETATION
- Urinalysis and urine culture as needed.
- Blood work:
  - Sodium: Interpretation depends on APD (affect renal function).
  - Chloride: Interpretation depends on APD (affect renal function).
  - Creatinine: Interpretation depends on APD (affect renal function).
  - Spot urine protein: Interpretation depends on APD (affect renal function).
- Postnatal US within 48–72 hr after birth may underestimate degree of hydronephrosis.
- Rare cases of pulmonary compromise from mass effect require emergent drainage.

Diagnostic Procedures/Surgery
- Postnatal evaluation: Controversial. Society of Fetal Urology (SFU) recommendations based on severity of PH (1)
  - Unilateral mild PH:
    - 1st postnatal US: 1–3 days after birth
    - VCUG: 1–7 days after birth
    - Consider diuretic nuclear renal scan (MAG-3) at 4 wk if hydro present on postnatal US
  - Unilateral moderate-severe PH:
    - 1st postnatal US: 1–3 days after birth
    - VCUG: 1–7 days after birth
    - Males: Early VCUG to rule out PUVs.
    - Consider diuretic nuclear renal scan (MAG-3) at 4 wk.
  - Bilateral moderate-severe PH:
    - Postnatal US: 1–3 days after birth
    - VCUG: 1–7 days after birth
    - Males: Early VCUG to rule out PUVs
    - Consider diuretic nuclear renal scan (MAG-3) at 4 wk.
- Special situations:
  - Bladder/urethral abnormalities, decreased amniotic fluid
  - Early evaluation similar to severe bilateral PH
  - Postnatal US within 48–72 hr after birth may underestimate degree of hydronephrosis.

Pathologic Findings
None.

DIFFERENTIAL DIAGNOSIS
- Urinary conditions:
  - Autosomal recessive polycystic kidney disease
  - Duplication anomalies
  - Ureteropelvic junction obstruction
  - Megacystis-microcolon intestinal hypoperistalsis syndrome
  - Autosomal recessive polycystic kidney disease
  - Autosomal recessive polycystic kidney disease
  - Prune belly syndrome
  - Urologic anomalies
  - Transient hydronephrosis
  - UPJ obstruction
  - Ureterocele
  - Vesicoureteral reflux
  - Intestinal disorders:
    - Intestinal atresia
    - Intestinal duplication
    - Meckel’s diverticulum
    - Gastrointestinal atresia
    - Persistent cloaca
    - Congenital nephrotic syndrome
    - Neuroblastoma

DIAGNOSIS
- N/A

DIFFERENTIAL DIAGNOSIS
- N/A

PATHOPHYSIOLOGY
- Genetics:
  - Most common is autosomal recessive.
  - Inheritance is autosomal dominant.
- Risk of clinically significant PH increases with severity.
  - Risk of undergoing surgery:
    - Severe: 2–13%
    - Moderate: 10–30%
    - Mild: 57–88%
- Incidence:
  - 1–5% of fetuses are observed to have PH (2).
- Prevalence:
  - In utero dilation of fetal renal collecting system made with certainty until 18 wk of gestation.
- Intrauterine severity.
  - Severe: >4 mm; moderate: 1–4 mm; mild: <1 mm.
- Postnatal severity:
  - Severe: >10 mm (2nd trimester); >7 mm (3rd trimester).
  - Moderate: 4–10 mm (2nd trimester); 7 to <10 mm (3rd trimester).
  - Mild: ≤4 mm (2nd trimester).

EPIDEMIOLOGY
- Associated with pulmonary hypoplasia and fetal/neonatal death.
- Additional prenatal US in 3rd trimester: Based upon severity of PH in 2nd trimester (1).
**HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PRENATAL**

**TREATMENT**

**GENERAL MEASURES**
- Pre-natal assessment: Measurement of hydronephrosis, oligohydramnios:
  - Unilateral cases: Serial prenatal US if severe; deliver at term
  - Bilateral cases:
    - No oligohydramnios: Observation, deliver at term
    - Oligohydramnios: Termination, early delivery, pre-natal treatment for pulmonary immaturity
- Post-natal management:
  - Pulmonary support if respiratory compromise
  - Antibiotic prophylaxis if moderate-severe unilateral or bilateral PN
  - Bladder/urethral abnormalities, dilated ureter, oligohydramnios (2)
  - Amoxicillin (20 mg/kg/d—1 dose per day)
  - Recommended by SFU with moderate-severe PN
  - Oligohydramnios: Termination, early delivery
  - No oligohydramnios: Observation, deliver at term

**ADDITIONAL TREATMENT**

**SURGERY/OTHER PROCEDURES**
- No specific antenatal medications exist
  - Prophylactic antibiotics controversial
  - Recommended by SFU with moderate-severe PN, bladder/urethral abnormalities, dilated ureter, oligohydramnios (2)
  - VCUG is not recommended for unilateral mild hydronephrosis
  - Tapping of fetal bladder
  - Frequent fetal interventions (cases with oligohydramnios only): Surfactant to assist lung function after birth with pulmonary hypoplasia

**MEDICATION**
- No specific antenatal medications exist
  - Prophylactic antibiotics controversial
  - Recommended by SFU with moderate-severe PN, bladder/urethral abnormalities, dilated ureter, oligohydramnios (2)
  - Amoxicillin (20 mg/kg/d—1 dose per day)
  - Surfactant to assist lung function after birth with pulmonary hypoplasia
  - Prophylactic antibiotics controversial.
  - No specific antenatal medications exist
  - Amoxicillin (20 mg/kg/d—1 dose per day)

**SECOND LINE**
- VA

**SURGERY/OTHER PROCEDURES**
- Fetal intervention (cases with oligohydramnios only):
  - Antibiotic prophylaxis if moderate-severe unilateral or bilateral PN
  - Bladder/urethral abnormalities, dilated ureter, oligohydramnios (2)
  - Amoxicillin (20 mg/kg/d—1 dose per day)
  - Surface to assist lung function after birth with pulmonary hypoplasia
- Surgery is seldom necessary in the neonatal period with the exception of severe bilateral obstruction due to bladder outlet obstruction or severe UPJ or UVJ obstruction.
- Need for post-natal surgery based upon diagnosis and correlated with severity of PN
  - Mild: ~10%
  - Severe: ~50%

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- VA

**Additional Therapies**
- VA

**Complementary & Alternative Therapies**
- VA

**ONGOING CARE**

**PROGNOSIS**
- Most neonates have an excellent prognosis.
- Prognosis depends on strategy of the dilated system and other associated anomalies.
- Severe bilateral hydronephrosis is associated with obstruction and oligohydramnios early in gestation predicts an adverse outcome.
- Resolves with bilateral hydronephrosis, a distorted bladder, and oligohydramnios are at highest risk of neonatal demise or pulmonary complications.
- Risk of UTI correlated with severity of PN
  - Mild: ~10%
  - Moderate-severe: ~30%

**COMPLICATIONS**
- Pulmonary hypoplasia with severe oligohydramnios
- Renal impairment
- UTIs

**FOLLOW-UP**

**Patient Monitoring**
- Based on initial evaluation, subsequent imaging may be necessary (3)
  - Most centres employ serial renal US every 3–6 mo for the 1st yr of life
  - If febrile UTI, consider VCUG and/or MAG-3 renal scan

**Patient Resources**
- http://urology.ucsf.edu/patient-care/children/hydronephrosis

**REFERENCES**

**ADDITIONAL READING**
- See Also (Topic, Algorithm, Media)
  - Hydronephrosis/Hydroureteronephrosis (Dilated Ureter/Renal Pelvis), Pediatric
  - Hydronephrosis/Hydroureteronephrosis (Dilated Ureter/Renal Pelvis), Pediatric Image (5)
  - Megaureter, Congenital

**CODES**
- ICD9 753.03 Other obstructive defect of renal pelvis and ureter
- ICD10 O62.0 Congenital hydronephrosis
- O62.10 Congenital bladder neck obstruction
- O62.39 Other obstructive defects of renal pelvis and ureter

**CLINICAL/SURGICAL PEARLS**
- Majority of prenatal/fetal hydronephrosis (especially mild) is transient with no clinical significance.
- VCUG is not recommended for unilateral mild hydronephrosis.
- Prophylactic antibiotics have not been shown to be effective. Not recommended in mild cases.
- Emergent evaluation by urologist should occur with:
  - Severe bilateral prenatal hydronephrosis
  - Severe unilateral prenatal hydronephrosis in solitary kidney
  - Fetal hydronephrosis with dilated bladder consistent with posterior urethral valves
  - Severe prenatal hydronephrosis with pulmonary compromise from mass effect (pneumothorax)
HYPERALDOSTERONISM, PRIMARY (ALDOSTERONISM, CONN SYNDROME)

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION
- Primary hyperaldosteronism or Conn syndrome is characterized by HTN, hypokalemia, hypernatremia, alkalosis, and suppressed renin, due to excess production of aldosterone.
- It classically refers to an aldosterone-producing adenoma (APA) of the adrenal gland that is usually small (<1 cm), unilateral, and non-irremovable.
- APA subtype of primary hyperaldosteronism accounts for 30–40% of primary hyperaldosteronism.
- Secondary hyperaldosteronism is usually related to HTN and/or endocrine state disorders such as CHF, cirrhosis, and nephrotic syndrome.
- Pseudohyperaldosteronism can be due to ingestion of large amounts of licorice or situ hormone.

EPIDEMIOLOGY

Incidence
- Incidence data is lacking.

Prevalence
- 5–15% of hypertensive population (recent increased prevalence of primary aldosteronism due to improved diagnostic testing)
- Peak incidence during 4th and 5th decades
- 20% primary aldosteronism in resistant hypertensives (defined BP despite ≥3 antihypertensive medications)
- Adrenal adenoma is more common in women.

RISK FACTORS
- No known risk factors for primary hyperaldosteronism

Genetics
- Hereditary pattern for more common APAs unclear
- Gene for aldosterone synthase (CYP11B2) recently identified

PATHOPHYSIOLOGY
- The biochemical hallmark of the disease is increased aldosterone after sodium (Na) loading and low plasma renin activity (PRA) during Na depletion
- Autonomic aldosterone secretion leads to inappropriate Na and water reabsorption from the cortical collecting tubule.
- Electrolyte-patient crushed favors secretion of potassium (K), resulting in hypokalemia.
- Intracellular fluid volume (ECF) volume causes mild hypertension (HTN).
- Renal escape limits Na retention and prevents significant edema:
  - Occurs after ~1.5 kg of extracellular fluid (ECF) is aborbed, or a weight gain of ~3 kg.
  - Spontaneous diuresis then occurs, lowering the ECF.
- Increased atrial natriuretic peptide (ANP), decreased bradycardia-sensitive Na+ C+ transporter, and pressure natriuresis are factors that may contribute to renal escape.

ASSOCIATED CONDITIONS
- Adrenal cancer (rare)
- Essential HTN

GENERIC PREVENTION
- N/A

DIAGNOSIS

HISTORY
- HTN often refractory to medical therapy
- Headaches secondary to HTN
- Symptomatic hypokalemia:
  - Muscle cramps, paresthesias, tetany, nocturia, polyuria

PHYSICAL EXAM
- No specific findings
- NIDDM to moderate HTN, not usually distinguishable from essential HTN
- Malignant HTN rare
- Lack of edema

DIAGNOSTIC TESTS & INTERPRETATION
- Consider screening the following patients (1):
  - Family history of early HTN or stroke
  - Essential HTN
  - Adrenal cancer (rare)
  - Hypokalemia can be induced with oral Na loading.
  - 20% of patients with hyperaldosteronism are normokalemic; more often seen in adenomas.
  - Inappropriate kaliuresis on initiation of diuretics
  - Aldosterone and cortisol samples obtained from peripheral veins, IVC, right and left adrenal veins
  - Adrenal scintigraphy using 123I-iodomethyl-19-norcholesterol is rarely available in US. Cerenkov to perform, and depends heavily on the size of the adenoma.

Confirmatory studies:
- N/A loading test with:
  - Sodium infusion: PAC at baseline and 4 hr
  - Positive test (PAC > 10 ng/mL)
- Oral Na: 24-hr urine Na and aldosterone on days 3 and 4 (positive if aldosterone > 12 mg/dL and Na < 200 mEq/L)
- Fludrocortisone suppression
- All confirmatory tests should be used with care in patients with compromised left ventricular cardiac function.

Imaging
- CT with thin cuts through the adenals is the preferred normative test
- Used to identify surgically curable disease and differentiate the subtypes once primary aldosteronism is confirmed
- Aldosterone-producing adenomas (APA’s) usually uniform, mixed, and hypodense with Hounsfield unit ≤10
- 4–6% probability of identifying an adrenal mass on CT
- Lack’s overall accuracy to distinguish between unilateral and bilateral disease.
- Bypass adrenal vein sampling only if clear adrenal mass (<1 cm) is identified in the younger patient (<40) with highly suspicious biochemical findings.
- MRI is not more sensitive than CT
- Adrenal imaging using
  - Isotopic 131I-i-iodomethyl-19-norcholesterol is rarely available in US. Cerenkov to perform, and depends heavily on the size of the adenoma.

Diagnostic Procedures/Surgery
- Adrenal vein sampling (AVS) for aldosteronism is the gold standard in localizing the site of excess production:
  - Aldosterone and cortisol samples obtained from peripheral veins, IVC, right and left adrenal veins
  - 44% of patients with bilateral renal masses had a unilateral source of aldosterone secretion.
  - Cure also reported after adrenalectomy in patients with AVS proven unilateral despite normal aldosteronism on CT scan.
  - Postural tests, historically used to distinguish adenoma from bilateral hyperplasia have become less useful with the discovery of angiotensin-competitive ARAs.

Pathologic Findings
- Solid, well-demarcated mass with the typical mottled yellow color of adrenal cortex
- Without diffuse thickening of the zona glomerulosa or hyperplastic nodules
- May compress the nonneoplastic uninvolved adrenal gland

Histopathology: Foamy lipid-laden clear cells, in sheets or nests

200
Differential Diagnosis
- Other causes of HTN. In evolving disease, aldosterone and renin will both be low. In renal artery stenosis, there will be high renin and high aldosterone.
- Other causes of HTN and hypokalemia, such as:
  - Overproduction of hormone
  - Use of diuretics
  - Hypercalciuria/hyperparathyroidism
- Other causes of primary hyperaldosteronism:
  - Renal artery stenosis
  - Renal vein stenosis
  - Hypertension (HTN) type 1, autosomal dominant
  - Familial occurrence of APA or bilateral idiopathic hyperplasia
  - Adrenal cancer producing aldosterone: Extremely rare
- Liddle syndrome: Autosomal dominant disorder. Mimics hyperaldosteronism and involves problems with excess resorption of Na and loss of K.

Treatment
General Measures
- Treatment selected based on etiology of hyperaldosteronism
  - Control HTN

Medication
First Line (2)
- Mineralocorticoid receptor antagonist used in those with bilateral adrenal hyperplasia and unilateral hyperplasia or APA who are not surgical candidates
  - Spironolactone: Limited due to affinity for androgen and progesterone receptors. Causing gynecomastia, sexual dysfunction, menstrual irregularities
  - Eplerenone: No active metabolites, shorter half-life than spironolactone, 50–75% as potent as spironolactone but less adverse effects
  - Thiazide diuretics, ACE inhibitors, calcium channel blockers

Second Line
- Amiloride, a diuretic that blocks the Na channel and K-sparing diuretic, may also be used, especially if spironolactone or eplerenone are intolerable. More often used in conjunction with the above.

Surgery/Other Procedures
- Unilateral adrenalectomy is indicated in patients with hyperaldosteronism due to an adenoma.
- HTN is cured or improved significantly in up to 90% of such cases. Usually takes 3–6 mo to see an effect.
- Adequate control of BP (see “Medications”) for several weeks and correction of metabolic abnormalities should be done before surgery.
- Obtain PCC after surgery to confirm cure
- Monitor K closely postoperatively

Additional Treatment
Radiation Therapy
- Additional Therapies
Emerging therapies include developing drugs that inhibit actions of aldosterone synthase enzyme, encoded on the CYF11 gene.

Icd9
- 253.10 Hyperaldosteronism, unspecified
- 253.12 Conn’s syndrome
- 253.14 Other secondary aldosteronism
- 253.14 Other secondary aldosteronism

Icd10
- E26.09 Other primary hyperaldosteronism
- E26.10 Hyperaldosteronism, unspecified
- E26.11 Conn’s syndrome
- E26.12 Secondary hyperaldosteronism
- E26.09 Other primary hyperaldosteronism
- E26.09 Other primary hyperaldosteronism

Clinical/Surgical Pearls
- Hypertension (HTN) with serum K < 3 meq/L is highly suspicious of an aldosterone-producing adenoma (APA).
- Treatment selection is based on etiology of hyperaldosteronism
- Surgical excision provides excellent control of hypertension in aldosterone-producing adenoma (APA)
- Control of the adrenal vein is the most important step during adrenalectomy.

HYPERPROLACTINEMIA, UROLOGIC CONSIDERATIONS

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION
• Hyperprolactinemia (HPRL) refers to serum prolactin levels that exceed the normal range (<25 mg/L; 150-400 mg/L) in men.
• It is the most common endocrine abnormality due to hypothalamic-pituitary disorders.
• It may result in hypogonadism, erectile dysfunction, infertility, galactorrhea, and osteoporosis.
• Most common causes are pregnancy, medications, hyperthyroidism, and prolactin-secreting pituitary tumors (prolactinomas).

EPIEMIOLOGY
Incidence
• Peak incidence occurs in women of age 25–34, at 23.9/100,000/yr.
• Incidence data in men is lacking.

Prevalence
• Lifetime prevalence of prolactinoma is 30/100,000 in woman and 10/100,000 in men.
• Pituitary microadenomas are found in 10.9% of autopsies, with 44% prolactinomas.
• In men with sexual dysfunction, ~1% have HPRL.
• 90% of prolactinomas occur in women of reproductive age.
• 40% of pituitary adenomas are prolactinomas.

RISK FACTORS
• Female sex
• Pregnancy
• Prolactinomas
• Medications (antipsychotics, antidepressants, verapamil, opiates, GI motility drugs, estrogens)
• MEN-1 syndrome

Genetics
• Most prolactinomas are sporadic (1)
• Present in about 20% of adults with MEN-1, who have an autosomal dominant mutation in the MEN-1 tumor suppressor gene on chromosome 11
• Can rarely occur as part of familial isolated pituitary adenomas

PATHOPHYSIOLOGY
• Prolation is produced in the anterior pituitary
• Secretion is pulsatile and increases with stress and sleep
• Toniaically suppressed by dopamine via D2 receptors
• Medications that inhibit dopamine secretion raise prolactin levels
• Elevated prolactin suppresses GnRH, with subsequent reductions in LH, FSH, and sex steroid levels
• Low testosterone can cause decreased libido, erectile dysfunction, infertility, and gynecomastia in men
• Low estrogen can cause atrophy of bone, decreased libido, anovulation, and galactorrhea in women
• Increased bone mineral density can occur in both sexes secondary to low sex steroid levels.

• Prolactinomas: Pituitary microadenomas (<10 mm) and macroadenomas (>10 mm) can be seen in some patients as the cause of the elevated levels.
• Macroadenomas can have mass effect symptoms, including headache and visual disturbance by optic nerve compression.
• Rarely, chest wall injury can incrase prolactin levels.
• Macroprolactinemia is caused by an abnormal binding of the molecule to circulating IgG.

ASSOCIATED CONDITIONS
• Amenorrhea and/or galactorrhea in women
• Hypothalamic and/or ED in men
• Hypothyroidism: Increased thyroid-stimulating hormone can stimulate prolactin secretion.
• Renal failure can result in reduced clearance.
• Cirrhosis
• Herpes zoster (particularly involving the chest wall)

GENERAL PREVENTION
• Discontinuation of medication causing symptomatic HPRL (asymptomatic prolactin elevations need not be treated)

DIAGNOSIS
HISTORY
• Women: Often presents early in disease course.
• Infertility (including pregnancy history)
• Amenorrhea/menstrual irregularities
• Complaints of sexual dysfunction
• Deceased libido
• Erectile dysfunction (ED)
• Gynecomastia
• General
• Headache
• Visual field deficits
• Psychic history and antipsychotic medication use
• Alcohol abuse

MEDICATION USE
• Antipsychotics: Buptyrophene, haloperidol, chlorpromazine, thioridazine, risperidone, and others
• Nonsteroidal anti-inflammatory drugs, aspirin, ibuprofen, naproxen, methylprednisolone, opiate
• Others reported: Antihypertensives, cimetidine, ciprofloxacin, erythromycin, trimethoprim-sulfamethoxazole, verapamil

PHYSICAL EXAM
• Breast exam for gynecomastia, galactorrhea
• Evidence of chest wall trauma or hepatic lesions
• Signs of hypothyroidism
• Signs of hyperpituitarism
• Visual field abnormalities

DIAGNOSTIC TESTS & INTERPRETATION
LAB 2
• A single serum measurement > upper limit of normal makes the diagnosis of HPRL
• Serum PRL > 900 μg/L is diagnostic of a macroprolactinoma
• Women of reproductive age should have a pregnancy test
• In men presenting with ED, a testosterone level should be checked. If low, further evaluation of prolactin should be performed
• With medication-induced HPRL, prolactin levels are usually <50 mg/L and almost always <100 mg/L
• After stopping suspected medication, prolactin levels usually return to normal within 4 days

Imaging
• Pituitary MRI is the test of choice. Should be obtained in all cases where prolactin is persistently elevated and no cause is apparent.
• MRI scanning to evaluate for possible bone mineral density problems
• In women, pelvic US to assess for uterine or ovarian pathology

Diagnostic Procedures/Surgery
• Formal visual field assessment should be done in patients with macroadenomas.

PATHOLOGIC FINDINGS
• Prolactinomas: Glands composed of cuboidal cells. May be either eosinophilic or chromophobic.
• Pathologic findings
• Formally, prolactinomas appear hypercellular, with a monotonous population of cells

TREATMENT
• General measures: Do not treat women until pregnancy is excluded.
• Men: Often presents late in disease course.

DIFFERENTIAL DIAGNOSIS
• Hypothyroidism:
• Lab error or macroprolactinoma (abnormal prolactin molecule)
• Medication-induced
• Nonprolactin-secreting pituitary or hypothalamic tumors
• Polyglandular syndrome (FGOS)
• Pregnancy
• Prolactinoma
• Renal failure

ALERT
• Do not treat women until pregnancy is excluded.

GENERAL MEASURES (3)
• Women of reproductive age should have a pregnancy test 1st.
• Treat underlying cause or stop offending drug if possible
• Asymptomatic HPRL secondary to medication use does not require treatment.
HYPERPROLACTINEMIA, UROLOGIC CONSIDERATIONS

REFERENCES

ADDITIONAL READING

CODES
ICD9
• 254.1 Other and unspecified anterior pituitary dysfunction
• 256.39 Other ovarian failure
• 257.2 Other testicular dysfunction

ICD10
• E22.1 Hyperprolactinaemia
• E28.3 Other primary ovarian failure
• E29.1 Testicular dysfunction

CLINICAL/SURGICAL PEARLS
• Women present early in the disease course, while men present late.
• Dopamine agonists are the 1st-line treatment of prolactinomas.
• Surgical excision is reserved for refractory cases.
• All women should be screened for pregnancy before initiating treatment.

ON GOING CARE

PROGNOSIS
• 90–95% of prolactin-secreting pituitary microadenomas will not grow further, even without medical therapy.
• Medical therapy is usually successful in normalizing prolactin levels, normalizing menses, reducing or stopping galactorrhea, inducing ovulation, and shrinking pituitary tumors.
• ~90% of microadenomas do not grow significantly during pregnancy, even after medical therapy is stopped.
• Some microadenomas disappear with time (especially after menopause) or do not recur after medical therapy.
• Pituitary macroadenomas usually do not disappear completely with medical therapy and require continuous medical therapy.

COMPLICATIONS
• Dopamine agonists can worsen underlying psychiatric problems in patients taking psychotropic medications.
• Pituitary macroadenomas can secrete other hormones or become resistant to medical therapy.

FOLLOW-UP
Patient Monitoring
• Drug induced HPRL: Prolactin should normalize after switching medications and no further follow-up is needed.
• Microadenomas:
  • Some microadenomas resolve spontaneously.
  • Measure prolactin every 6–12 mo to ensure continued drug efficacy.
  • No need for repeat pituitary MRI unless prolactin increases markedly on therapy.
  • Consider stopping dopamine agonist after at least a year of successful therapy, some microadenomas do not recur.

• Macroadenomas:
  • If prolactin normalizes, repeat pituitary MRI after 3–6 mo to ensure tumor shrinkage and establish new baseline.
  • No consensus on frequency of further MRIs in patients whose prolactin is well-controlled medically.
  • Repeat prolactin measurements every 3–6 mo.
  • Follow visual fields in patients who have visual field defects at baseline.
  • Some macroadenomas resolve spontaneously.

Patient Resources
Patient guide to hyperprolactinemia is diagnosis and treatment. J Clin Endocrinol Metab. 2011;96:35A–36A.

PREGNANCY CONSIDERATIONS
• All women should be screened for pregnancy before initiating treatment.

FIRST LINE THERAPIES
• Cabergoline or bromocriptine (dopamine agonists): Usually will lower prolactin levels, regardless of cause, and shrink microadenomas.

SURGERY/OTHER PROCEDURES
• Cabergoline or bromocriptine (dopamine agonists): Usually better tolerated, more convenient, and more effective than bromocriptine, whereas bromocriptine is less expensive and has been used longer.
• Use dopamine agonists with caution in patients on psychotropic drugs that inhibit dopamine action.

Surgical excision is reserved for refractory cases.

ADDITIONAL TREATMENT
• Cabergoline dosing (0.5-mg tablets): Start with 0.25–0.5 mg once or twice weekly and increase the dose at monthly intervals until prolactin normalizes (> 3 mg/L is overly needed).
• Bromocriptine dosing (2.5-mg tablets): Start with 0.625 or 1.25 mg with food before bedtime and gradually increase at weekly intervals until prolactin level is controlled (usually 2.5 mg BID–TID).
• Surgical excision is reserved for refractory cases.

ADDITIONAL READING

MEDICATION

First Line
• Cabergoline or bromocriptine (dopamine agonists):
  • Usually will lower prolactin levels, regardless of cause, and shrink microadenomas.
  • In general, both cabergoline and bromocriptine are effective. Cabergoline is usually better tolerated, more convenient, and more effective than bromocriptine, whereas bromocriptine is less expensive and has been used longer.
  • Use dopamine agonists with caution in patients on psychotropic drugs that inhibit dopamine action.
• Cabergoline dosing (0.5-mg tablets): Start with 0.25–0.5 mg once or twice weekly and increase the dose at monthly intervals until prolactin normalizes (> 3 mg/L is overly needed).
• Bromocriptine dosing (2.5-mg tablets): Start with 0.625 or 1.25 mg with food before bedtime and gradually increase at weekly intervals until prolactin level is controlled (usually 2.5 mg BID–TID).
• Side effects include nausea and postural hypotension.
• Pregnancy considerations:
  • More experience with bromocriptine.
  • Neither bromocriptine nor cabergoline has been associated with teratogenicity.
• Nevertheless, either drug is usually stopped at the 1st evidence of pregnancy, except in patients with microadenomas in whom previous mass effects may recur if tumor enlarges.
• Significant enlargement of microadenomas is uncommon during pregnancy.
• Lactation: Dopamine agonists will inhibit lactation.
• Significant enlargement of microadenomas is uncommon during pregnancy.
• Lactation: Dopamine agonists will inhibit lactation.
• Significant enlargement of microadenomas is uncommon during pregnancy.
• Lactation: Dopamine agonists will inhibit lactation.

Second Line
N/A

SURGERY/OTHER PROCEDURES
• Often performed transphenoidally.
• For microadenomas, generally reserved for patients intolerant of drug therapy. Tumors may recur.
• Only indicated for pituitary microadenomas when medical therapy is ineffective, including persistent visual field abnormalities.
• Usually do not curative

ADDITIONAL TREATMENT

Radiation Therapy

Usually only indicated for pituitary microadenomas that have failed medical therapy, and where response to surgery is inadequate or surgery is contraindicated.

Additional Therapies
Men with ED or persistent hypogonadism may require additional therapies.

Complementary & Alternative Therapies

Vitex agnus-castus extract can be tried in cases of mild HPRL.
HYPOSPADIAS
Steve J. Hodges, MD
Anthony Atala, MD

DESCRIPTION
Common congenital disorder of male external genitalia characterized by a ventrally displaced urethral meatus.
- Associated conditions may include:
  - Ventral chordee
  - Incomplete foreskin with dorsal hood and ventral deficiency
- May be an isolated defect or may be associated with a significant underlying abnormality
- Classification:
  - Anterior (distal) 50%: Glandular, coronal, subcoronal, megameatus intact prepuce
  - Middle (midshifty) 30%
  - Posterior (proximal) 20%: Penoscrotal, crural, perineal

EPIDEMIOLOGY
Incidence
- 1 in 250–300 live male births
- 1 in 80–100 in family history of hypospadias
Prevalence
Prevalence in US for hypospadias ranges between 2.01 and 56.17 per 10,000.
Incidence
2–12% have upper tract anomalies (horseshoe kidney, renal ectopia, duplicated ureters, others)
5% of cases have genetic cause
- Genetics (see below)
- Examples include environmental chemicals such as bisphenol A (BPA) and hormones used during pregnancy such as progesterone.
- Not possible except by avoidance of environmental agents or medications with estrogenic effects by pregnant women (see “Risk factors”)

ASSOCIATED CONDITIONS
- Associated conditions may include:
  - Ventral chordee
  - Incomplete foreskin with dorsal hood and ventral deficiency
  - May be an isolated defect or may be associated with a significant underlying abnormality
  - Classification:
    - Anterior (distal) 50%: Glandular, coronal, subcoronal, megameatus intact prepuce
    - Middle (midshifty) 30%
    - Posterior (proximal) 20%: Penoscrotal, crural, perineal

PATHOPHYSIOLOGY
- Normal penile development:
  - Urogenital folds form on either side of the cloacal membrane, and fuse anteriorly at the genital tubercle
  - Lateral labioscrotal folds fuse posteriorly and separate the urogenital and anal membranes
  - Under influence of testosterone and DHT, phallus elongates and the genital folds fuse in the midline to enclose urethra proximally to distally
  - Canalization of the glans occurs distally, fusing with urethra
  - Process complete by 20th wk of gestation
- Glanular hypospadias likely represents failure of distal canalization
- Proximal hypospadias due to failure of fusion of genital folds
- Scrotal or perineal variants result inชาft occlusion

ASSOCIATED CONDITIONS
- Growth restriction (low birth weight and length, small head circumference) has been associated with hypospadias
- Associated anomalies are more common in cases of severe hypospadias:
  - Cryptorchidism (7–9%)
  - Inguinal hernia/hydrocele (9–16%)
  - Syndromes:
    - 49 described in which hypospadias is frequent or occasional (Anemia-Wilms tumor association, Beckwith-Wiedemann, Smith-Lemli-Opitz, Triosity syndromes, Apert, Saethre-Chotzen, TAR, VACTERL association, XX, Trisomy 13, 18, V-CAP-BL association, XX, Zellweger, and many others)
    - 78% of these have associated micrognathia, cryptorchidism, and/or crural anomaly
    - In presence of hypospadias and cryptorchidism must rule out intersex condition (15% with true hermaphroditism)
    - Mixed gonadal dysgenesis
    - Partial androgen insensitivity
    - True hermaphroditism

GENETIC TESTING
- Genetics (see above)
- <5% of cases have genetic cause (3)
- 5% incidence in IVF births compared to controls
- Environmental:
  - Because of increases in rates in certain areas an association with chemicals with estrogenic or antiandrogenic effects has been suggested
  - Examples include environmental chemicals such as bisphenol A (BPA) and hormones used during pregnancy such as progesterone.
  - Genetics
- In cases of proximal hypospadias associated with an undescended testicle differential should include:
  - Congenital adrenal hyperplasia
  - Mixed gonadal dysgenesis
  - Partial androgen insensitivity
  - True hermaphroditism

DIAGNOSIS
HISTORY
- Family history of hypospadias
- Any associated congenital anomalies
- Exposure of mother to hormonally active agents during pregnancy
- IVF may increase risk of hypospadias

PHYSICAL EXAM
- Determine location of urethral opening
- Evaluate for chordee
- Evaluate for cryptorchidism
- Evaluate presence of inguinal hernia, hydrocele, or cryptorchidism
- Severe proximal hypospadias may be associated with bifid scrotum and/or penoscrotal transposition
- Look for other congenital anomalies

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Karyotype and hormonal evaluation to rule out intersex condition
  - In cases of severe hypospadias and cryptorchidism

Imaging
- No routine imaging necessary for routine hypospadias evaluation
- In setting of intersex evaluation, genitogram or perineal US may be performed
- VCUG in proximal hypospadias may demonstrate prominent prostatic utricle

Diagnostic Procedures/Surgery
- Pathologic Findings
- N/A

DIFFERENTIAL DIAGNOSIS
- In cases of proximal hypospadias associated with an undescended testicle differential should include:
  - Congenital adrenal hyperplasia
  - Mixed gonadal dysgenesis
  - Partial androgen insensitivity
  - True hermaphroditism

ALERT
- Do not perform circumcision in the setting of hypospadias. Hypospadias in the presence of cryptorchidism may signal an intersex disorder.
HYPOSPADIAS

TREATMENT

GENERAL MEASURES (2)
The general tenets of repair are to move the urethral meatus to an orthotopic location, straighten the penis (repair chordee), and either remove or modify the foreskin to give the appearance of a normalcircumcised or uncircumcised penis.

MEDICATION

First Line
• There is no specific medical therapy for hypospadias.

Surgery/Other Procedures
• Indicators of repair (1):
  – Proximal hypospadias: 1 stage—Thiersch–Duplay,
  – Midshaft hypospadias: Tubularized incised plate
  – Distal hypospadias: MAGPI, Thiersch–Duplay,
  – Chordee should be repaired 1st (orthoplasty)
  – Techniques dictated by meatal location, degree of
  – Timing of repair is ideal at 4–6 mo of age,
  – Goals are to create a cosmetically normal
  – 25–50 mg of testosterone propionate given IM
  – However, although a preference for the use of

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
• Patient may need revisions for chordee, meatal issues, or recurrent chordee at later dates

Complementary & Alternative Therapies
Psychosocial support for patient and family if needed

ONGOING CARE

PROGNOSIS
Most patients have normal penile function for voiding, sexual performance, and infiltration.

COMPPLICATIONS
• Early
  – Bleeding/hemorrhage—treated with compression or surgical exploration; infection—treated with antibiotics or incision and drainage;
  – Skin/tissue—treated with appropriate antibiotics;
  – Wound dehiscence—requires respiration 6 mo
• Late
  – Residual/recurrent chordee—treated with
  – Meatal stenosis—treated with meatal dilation or
  – Urethral stricture—treated with dilation or
  – Meatal stenosis—treated with meatal dilation or
  – Urethral stenosis—treated with dilatation or
  – Urethral diverticulum—treated with excision and repair;
  – Meatal stenosis—treated with meatal dilation or
  – Urethral stricture—treated with dilatation or
  – Urethral strictures—treated with complete excision and
  – Wound dehiscence—requires respiration 6 mo
• Late
  – Residual/recurrent chordee—treated with
  – Meatal stenosis—treated with meatal dilation or
  – Urethral stricture—treated with dilation or
  – Meatal stenosis—treated with meatal dilation or
  – Urethral strictures—treated with complete excision and
  – Wound dehiscence—requires respiration 6 mo

FOLLOW-UP

Patient Monitoring
• Follow-up for observation of penile development and complications noted above
• Children may present after toilet training or even as late as adolescence with newly diagnosed complications from repair as an infant.

Patient Resources
Urology Care Foundation http://www.urologyhealth.org/urologyindex.cfm?artid=130

CODES

ICD9
• 752.61 Hypospadias
• 752.63 Congential chordee
• 752.69 Other penile anomalies

ICD10
• Q54.9 Hypospadias, unspecified

CLINICAL/SURGICAL PEARLS

• More severe cases (proximal) more likely to be associated with an intersex disorder
• All members of the health care team must clearly understand that circumcision should not be performed if hypospadias is present.
IMMUNOCOMPROMISED PATIENTS, UROLOGIC CONSIDERATIONS

Patrick J. Shenot, MD, FACS

Nathan Roberts, MD

BASICS

DESCRIPTION

Immunocompromised patients have attenuated immune responses caused by:

- Immunosuppressive drugs (chemotherapy)
- Radiation (bone marrow irradiation)
- Hematopoietic stem cell transplant
- Malnutrition
- Disease processes (HLA, lymphoma, congenital immune deficiencies, autoimmune disorders)

Immunocompromised patients are at risk for opportunistic infections:

- Hematopoietic stem cell transplant
- Need preparative regimen to prevent rejection of transplanted graft: Complete myeloablative, Nonmyeloablative or 1+ chemotherapy
- Miliary tuberculosis
- Hematogenous dissemination of Mycobacterium tuberculosis
- HIV infection is common, 38% with military TB patients also have HIV

EPIEMIOLOGY

Incidence

- HIV infections: 1.2 million Americans
- Hemorrhagic cystitis (HC) (1)
- Tuberculosis
- HIV/AIDS: Protection during sexual activity; universal precautions for healthcare professionals

EPIDEMIOLOGY

- HIV/AIDS: 1.2 million Americans
- Hemorrhagic cystitis (HC) (1)
- Tuberculosis
- HIV/AIDS: Protection during sexual activity; universal precautions for healthcare professionals

HIV/AIDS

- Increased degree of immunosuppression
- BK virus Hemorrhagic cystitis (HC)
- Early onset Hemorrhagic cystitis (HC)
- Conditioning regimen used for hematopoietic stem cell transplant (HSCT) with cyclophosphamide, busulfan, or with antithymocyte globulin (4)
- Donor–recipient gender mismatch
- Late onset Hemorrhagic cystitis (HC)
- Allogenic HSCT transplant
- Graft versus host disease (GVHD)
- Use of corticosteroids or cyclosporine for GVHD
- Use of T cell depleted grafts
- HIV/AIDS: Protection during sexual activity; universal precautions for healthcare professionals
- Military tuberculosis: Treatment of latent TB can prevent miliary TB

PATHOPHYSIOLOGY

- Need for blood transfusions
- Graft versus host disease (GVHD)
- Allogenic HSCT transplant
- Donor–recipient gender mismatch
- Conditioning regimen used for hematopoietic stem cell transplant (HSCT) with cyclophosphamide, busulfan, or with antithymocyte globulin (4)
- BK virus Hemorrhagic cystitis (HC)
- Early onset Hemorrhagic cystitis (HC)

- Use of T cell depleted grafts
- HIV/AIDS: Protection during sexual activity; universal precautions for healthcare professionals
- Military tuberculosis: Treatment of latent TB can prevent miliary TB
IMMUNOCOMPROMISED PATIENTS, UROLOGIC CONSIDERATIONS

PHYSICAL EXAM
- **HC**
  - May present with palpable bladder if in clot retention
- **HIV/AIDS**
  - Most common intrascrotal pathology in AIDS is testicular atrophy
    - Secondary to endocrine imbalances, febrile episodes, malnutrition, tubercular infections, and toxic effects of therapeutic agents
  - **Prostatitis**
    - Boggy prostate
    - Crystal swelling/needle pain
  - Epididymitis/testicular pain caused by common and uncommon organisms (Candida, CMV, toxoplasmosis)
  - **Voiding dysfunction**
    - May have enlarged prostate

**Miliary tuberculosis**
- Pulmonary: Course breath sounds on auscultation, may have lymphadenopathy
- Genitourinary involvement
  - Possible costovertebral angle tenderness
  - Epididymal/prostate tenderness

DIAGNOSTIC TESTS & INTERPRETATION

**Lab**
- **HIV/AIDS**
  - HIV ELISA for anti-HIV-1 and 2
    - >99% sensitivity; Western blot to exclude false-positive but also to confirm HIV diagnosis
  - Plasma HIV RNA
    - Detectable by day 12; antibodies detected day 21
    - Used to assess treatment response/failure
  - HIV-associated nephropathy: Proteinuria-increased creatinine
- **Tuberculosis**
  - PPD; may be false negative
  - Mycobacterial blood culture
  - Ultrasound: Stone pain, possible hematuria
  - Urine and fast bacillus (FAB) culture

**Imaging**
- **HC**
  - CT with and without contrast: Can show clot, filling defect, calculus
- **HIV/AIDS**
  - **Bilateral**
    - CT non contrast may be associated with minimal findings with indwelling calculus
  - Kidney infection
    - CT scan: Can see striated nephrogram in pyelonephritis, abscess
- **Tuberculosis**
  - Chest radiograph (miliary disease)
    - Pain, reticulonodular infiltrate distributed fairly uniformly throughout the lungs
  - ESR findings: QSP (similar to normal value. Larger may indicate caseous lesions or chronicity and fibrosis from autonephrectomy
    - Autonephrectomy: Diffuse, uniform, extensive parenchymal, putty-like calcification, a lobed cast of the kidney
    - Calcifications in 30–50% of cases
    - Calculi may also be seen in the collecting system or urinary tract due to stricture formation
    - Urethral calcifications are rare and are characterized by intraluminal calcifications
  - Bladder wall calcifications are not very common except in late cases of bladder infection
    - Calculi may also be seen in the collecting system or urinary tract due to stricture formation
    - Renal parenchymal masses and scarring
    - Thick urinary tract walls
    - Tuberculoma: Renal mass coalescing caseating granulomas
  - Can see hydroptysis
  - Sensitivity in seeing the calcifications
  - Contrast can evaluate function of the kidney
  - Ultrason: Limited in diagnosis, Can be used for monitoring disease progression

**Pathologic Findings**
- **Tuberculosis**
  - Granulomatous inflammation
  - Contains epithelial macrophages, Langhans giant cells, and lymphocytes
  - Contains caseation necrosis
  - Organisms may or may not be seen with acid-fast staining
  - **HIV**
  - HIV-associated nephropathy (HIVAN)
  - Collapsing form of focal segmental glomerulosclerosis
  - Dilated tubules and interstitial inflammation

**Differential Diagnosis**
- **HC**
  - Infectious source
  - Bacterial
  - Viral BK vs adenovirus, CMV, JC, and herpes
- **HIV**
  - **Voiding dysfunction**
  - Patient may have underlying neurologic opportunistic infection

**Diagnostic Procedures/Surgery**
- **HC**
  - Cystoscopy, possible ureteroscopy
- **HIV/AIDS**
  - Kidney biopsy: Help to diagnose HIV-associated nephropathy (HIVAN)
  - Voiding dysfunction
  - Mayo-want UDS, may uncover neurogenic voiding dysfunction
  - Post-void residuals, cystoscopy
  - **Tuberculosis**
    - Biopsy of the following can demonstrate granulomas and be used for culture: lung, bone marrow, lymph nodes, bones, joints, liver, brain, and other tissues
    - Cystoscopy/retrograde pyelograms
      - Limited in diagnosis: Stricture, acute UO inflammation, acute tubulobular ulce, Golf hole ulcer. Circumferential and often excessively lateral unusual orifice
Reduction of immunosuppression (if possible) can help to reduce clinical sequelae. HIV patients have higher risk of bladder infections than non-HIV patients. Salmonella is of particular concern due to high-risk fatal recurrence (may need chronic suppression).

**MEDICATION**

**First Line**
- **HC**
  - Increased hydration
  - Catheter placement with clot evacuation
  - Continuous bladder irrigation (CBI)
- **HIV/AIDS**
  - Antiretroviral therapy (ART)
  - Miliary TB (3)
    - Standard pulmonary therapy
    - Often directly observed therapy
    - Isoniazid (INH), rifamycin (rifampin), pyrazinamide, and ethambutol for 2 mo
    - Isoniazid and rifamycin for additional 4 mo

**Second Line**
- **HC**
  - Conjugated estrogens
    - Act by stabilization of microvasculature
    - Oral vs. intravenous administration
  - Intravesical instillation of Alum
    - An astringent precipitates protein over bleeding surface
  - E-aminocaproic acid
    - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
  - Conjugated estrogens
    - Act by stabilization of microvasculature
  - Intravesical instillation of silver nitrate
    - Chemical caugetion and coagulation at bleeding sites
  - Intravesical instillation of formalin (40% formaldehyde)
    - Hydrolize proteins and coagulates tissue on superficial level
  - E-aminocaproic acid
    - Inhibits fibrinolysis preventing activation of plasminogen to plasmin

**Surgery**
- **HIV/AIDS**
  - Kidney infection abscess (Aspergillus and toxoplasma)
    - Percutaneous or open drainage
  - Prostatic abscess
    - Percutaneous (transrectal or transperineal)
  - Transurethral resection (TUR)
  - Testicular and epididymal infections
    - If intractable pain may warrant epididymectomy or orchectomy
- **Tuberculosis**
  - Often will proceed 3–6 wk after medications
  - Abscess drainage
  - Urethral or balloon catheter drainage
  - Percutaneous drainage
  - Nephrectomy
  - Prostatic abscess
    - Urinary tract infection (UTI)
    - Can treat with prolonged 3–10 day course of antibiotics
  - Epididymitis
    - Should be treated with antibiotics
    - Opportunistic infections should be suspected if not resolving
    - Vescicoureteral reflux
  - Partial nephrectomy
    - Caseating abscess that has not responded to medical therapy or firm swelling that has remained unchanged or increased in size with medical therapy
    - Augmentation cystoplasty (<100 cc capacity) vs. orthotopic bladder substitution (20 cc capacity)

**SURGERY/OTHER PROCEDURES**
- **HC**
  - Hyperbaric oxygen therapy
    - 100% oxygen in a hyperbaric chamber at 2.5 atmospheres absolute for 90 min 5 days a week.
  - Nephrectomy: If kidney is nonfunctioning, there is extensive disease involving the whole kidney, coexisting renal carcinoma
  - Partial nephrectomy
  - Epididymectomy: Caseating abscess that has not responded to medical therapy or firm swelling that has remained unchanged or increased in size with medical therapy
  - Augmentation cystoplasty (<100 cc capacity) vs. orthotopic bladder substitution (20 cc capacity)
IMMUNOCOMPROMISED PATIENTS, UROLOGIC CONSIDERATIONS

ADDITIONAL TREATMENT

**Additional Therapies**
- Oxazaphosphorine (cyclophosphamide)-induced HC
  - Mesna
  - Binds to acrolein and inactivates it
  - Supra hydration
  - Prophylactic Continuous bladder irrigation (CBI)
  - Often occurs within 72 hr

**ONGOING CARE**

**PROGNOSIS**
- HIV/AIDS
  - Greatly improved in the era of HAART therapy
  - CANCer
  - Rectal: 8-fold higher incidence
  - Testicular cancer: 2-fold increase in seminoma
- Miliary tuberculosis
  - Greatly improved with the introduction of antibiotics
  - Mortality previously 100% (pre-antibiotics) now 20%

**COMPLICATIONS**
- Increased risk for malignancy in immunosuppressed patients
- HIV/AIDS
  - 3.5% of HIV-infected patients will experience HIV-associated nephropathy
  - Caucasian patients: 12:1 risk
  - Intravenous drug use and men who have sex with men association
- Tuberculosis
  - Peritoneal nephrectomy (PCN)
  - Tuberculous fistula formation
  - Urinary stenting
  - Limit high-pressure contrast injection during retrograde pyelogram may disseminate infection

**FOLLOW-UP**

**Patient Monitoring**
- Hemorrhagic cystitis (HC)
  - Cyclophosphamide
  - 9-fold increase in urothelial carcinoma
  - 10-yr latency period

**CLINICAL/SURGICAL PEARLS**
- Recurrent UTI in the absence of infections in other organ systems, is not a typical presentation of an immunocompromised patient.
- Most common intrascrotal pathology in AIDS is testicular atrophy.
INCONTINENCE, URINARY, ADULT FEMALE
Debra L. Bronner, MD
Drew A. Freilich, MD

BASICS
DESCRIPTION
Incontinence is broadly defined as the loss of urine that is objectively demonstrable and is of social and hygienic concern.

PHYSIOLOGY
Stress urinary incontinence (SUI) occurs with increased intra-abdominal pressure without detrusor contraction.

RISK FACTORS
Advanced age, smoking, pregnancy, obesity, menopause, COPD, cognitive impairment, and advanced age.

EPIDEMIOLOGY
Incidence
Prevalence
Affects 30–50% of adult women
Stress urinary incontinence is the most common (40%), followed by mixed (20%) and urge (21%) incontinence.

Epidemiology

RISE PATHOPHYSIOLOGY
Stress incontinence occurs with increased intra-abdominal pressure without detrusor contraction.

Anatomy: Due to urethral hypermobility from lack of pelvic support.

Hammond theory: Normally, the suburethral support contributed by the endopelvic fascia and anterior vaginal wall provides a stable backboard against which the urethra is compressed while intra-abdominal pressure rises. When this suburethral support layer is lax and mobile, any effective compression is not achieved, causing leakage.

Intrinsic sphincter deficiency (ISD): Impairment of urethral mucosal seal and inherent closure from collagen, fibroelastic tissue, smooth and striped muscles. May be lost secondary to surgical scarring, radiation, or hormonal and menopausal changes

PATHOLOGY
Upper urinary tract anomalies may cause stress incontinence.

URGENCY INCONTINENCE: Detrusor overactivity (may be secondary to detrusor myopathy or neuropathy).

OK: Urinary retention (usually from lower motor paralytic, neurogenic bladder in women).

TOTAL INCONTINENCE: Constant loss of urine. Ectopic ureters in females usually open in the urethra distal to the sphincter or in the vagina, causing continuous leakage.

SUPPORT FIBROUS TUMOR (or intrapelvic leiomyoma) in history of radiation.

COTAL INCONTINENCE: Up to 60% of women who report incontinence appear to leak urine during intercourse.

ASSOCIATED CONDITIONS
Pelvic organ prolapse
Diabetes
Neurologic disease (e.g., multiple sclerosis, Parkinson’s disease)

GENERAL PREVENTION
Weight loss
Optimization of medical health (e.g., diabetes)
Smoking cessation

DIAGNOSIS
HISTORY
Part II: Weakness of the pelvic floor is more likely in multiparous women leading to SUI.

Amount and frequency of leakage
Continuous slow leakage in between regular voiding
Continuous leakage: Ectopic ureter, urinary fistulas, Nocturnal enuresis: Idiopathic, neurogenic, or iatrogenic

Urgency incontinence: Can be due to urinary tract, duplicated systems for ectopic ureters, and infection associated pathologies (indicated only when upper tract issues are suspected).

DIAGNOSTIC TESTS & INTERPRETATION
Lab
-Urine analysis
-Urine culture: Assess for infection

Imaging
-CSTogram: Determines status of upper urinary tract, duplicated systems for ectopic ureters, and infection associated pathologies (indicated only when upper tract issues are suspected).

Voiding cystourethrogram: Preferably done in combination with videourodynamics studies

Diagnostic Procedures/Surgery
-24-hr voiding diary to assess frequency, timing, volume of symptoms
-Cystoscopy: If concern for fistula or malignancy
-Urinal cytology: If hematuria and urgency (concern for carcinoma in situ)
-Urodynamic studies:

Pelvic suburethral support is bowel filling.

Assess Valsalva leak point pressure: Determines the intra-abdominal pressure at which leakage is observed at the meatus or by fluoroscopy. Low leak point pressure (< 60 cm H2O) implies ISD.

Assess detrusor leak point pressure: Increased detrusor pressure at which leakage of urine occurs in absence of detrusor contraction and increase abdominal pressure (> 40 cm H2O risk on renal deterioration).

Voiding cystometry: Pressure/volume relationship during micturition.

Assess urinary flow rate, postvoid residual, detrusor sphincter synergy.

Urodynamic studies: Combination of fluorourodynmenography and urodynmy studies mentioned above.

Most useful in patients at risk for neurogenic bladder to assess for detrusor sphincter dyssynergia which is risk for renal deterioration

Pathologic Findings

DIFFERENTIAL DIAGNOSIS
-Stress incontinence: Due to urethral hypermobility or ISD, although in the majority is mixed or due to both of the factors.

-Urgency incontinence: Can be due to urinary infection, interstitial cystitis, carcinoma in situ, bladder cancer, detrusor overactivity, or neurogenic detrusor overactivity. Most often idiopathic

-Nonspecific enuresis: Idiopathic, neurogenic, cardiogenic, or obstructive causes

-Corticosteroid therapy, interstitial cystitis, endometriosis-related complex

-Postcoital blushing: Urethral diverticulum, idiopathic or uretogenic

-Mobility or cognitive impairment post stroke

-Coronal or mixed incontinence
TREATMENT

GENERAL MEASURES (1)
- Non-surgical management (helps ~ 50–65% patients with milder symptoms)
- Treat constellate causes (iatrogenic, cardiovascular, diuretic, etc.)
- Encourage weight loss in obese patients
- Biofeedback and pelvic floor exercises (Kegel exercises) (2)
- Behavioral therapy: Voiding at progressively increasing predetermined intervals

MEDIATION

First Line (2)
- Stress urinary incontinence: Activation of urogenital straining increases the urethral resistance to urinary flow with symphysiophoric diap septum, estrogen, and tricyclic antidepressant medications have been used to treat this type of bladder symptoms.
- Mirabegron (25–50 mg/d) is a first-line agent for treatment of urge incontinence. When compared to anticholinergic medications, it has less dry mouth and constipation, but it is more expensive.

Second Line
- Anticholinergic, antispasmodic, and tricyclic antidepressant medications have been used to treat neurogenic bladder symptoms.
- α1 blockers used to treat overactive bladder symptoms
- ≤ 3-agonist for refractory UI

- Intravesical botulinum toxin for neurogenic overactive bladder (NDO/1)
- Percutaneous tibial nerve stimulation
- Sacral neuromodulation: Efficacy ∼ 80% in those refractory to other modalities (4)
- Catheter-related complications can result from long-term indwelling catheters, such as recurrent UTIs, skin infections, and urethral erosion.

FOLLOW-UP
- Initial postoperative assessment after midurethral slings: Evaluate voiding function with estimation of postvoid residual and need for intermittent catheterization.
- Periodic long-term follow-up with validated outcome-based questionnaire surveys

Ongoing Care
- Initial postoperative assessment after midurethral slings
- Catheter-related complications can result from long-term indwelling catheters, such as recurrent UTIs, skin infections, and urethral erosion.

ADDITIONAL TREATMENT

Radiation Therapy
- Radiotherapy overactive bladder

Additional Therapies
- Reducer or avoidance of spicy foods, citrus, or chocolate; limiting excessive fluid intake and caffeine can improve symptoms of urinary incontinence (especially if overactive bladder)
- Complementary & Alternative Therapies
- No high level data to support

ADDITIONAL READING

CODING
- ICD-10: N39.41 Urge incontinence
- N39.40 Stress incontinence
- 788.30 Urinary incontinence, unspecified
- 788.31 Urge incontinence
- 746.8 Stress incontinence, female
- R32 Unspecified urinary incontinence
- R32.5 Stress incontinence
- R32.3 Urge incontinence
- R32.41 Urge incontinence

CLINICAL/SURGICAL PEARLS
- Recent FDA alerts regarding vaginal mesh applies to prolapse repair and not midurethral slings. Mesh for stress incontinence has been supported in multiple randomized controlled trials.
- Consider reduction of pelvic organ prolapse as part of evaluation for incontinence.
- Consider referral to urologist in young patients with refractory idiopathic overactive bladder as 1st presenting symptom of multiple sclerosis or isolated urinary urgency in ~ 15%.
INCONTINENCE, URINARY, ADULT MALE
Michael J. Anvari, MD
Patrick J. Shenot, MD, FACS

DIAGNOSIS

HISTORY
- Voiding symptoms
  - Duration and characteristics of incontinence
  - Stress, urge, total
  - Precipitants and associated symptoms
  - Use of pads, briefs, diapers
  - Fluid intake
  - Alteration in bowel habits
  - Previous treatments and effect on incontinence
- Diabetes mellitus
- Associated conditions
- Neurologic disease
- Medication use
- Deinits
- Alcohol and drug use including caffeine
- Radical pelvic surgery or radiation
- Abdominoperineal resection
- Radical prostatectomy

PHYSICAL EXAM
- Abdominal exam
  - Sigmoidoscopy
  - Suggests retention
  - Proctoscopy
  - Suggests U/TI
  - Surgical scars suggesting pelvic surgery
  - Suprapubic tenderness
  - Skin lesions associated with neurologic disease
  - Vascular malformation, tuft of hair, or skin dimple on lower back
  - Cauda equina sign
  - Low, short gluteal cleft
  - Coccyx not palpable
  - Inspect muscle for atrophy
  - Coccyx not palpable
  - Rectal neurologic exam
  - Motor function
  - Posterior tibial (S1–S2): Ankle plantar flexion
  - Anterior tibial (L4–S1): Dorsiflexion of foot
  - tibialis anterior (L4–S1): Dorsiflexion of first metatarsal
  - Perineal tenderness

ASSOCIATED CONDITIONS
- Neurologic disease
- Pelvic disease, multiple sclerosis
- Pelvic trauma
- Bladder surgery

GENERAL PREVENTION
None

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Creatinine
- 8–11 mg/dl
- If significant retention suspected
- Urinalysis
- Glucosuria, infection

Imaging
- None usually indicated

Diagnostic Procedures/Surgery
- Urodynamics
- Useful for confirming bladder outlet obstruction as possible cause of detrusor overactivity

Pathologic Findings
- None

DIFFERENTIAL DIAGNOSIS
- Urge incontinence
- Loss of urine accompanied by urgency, often related to triggers such as sounds of running water, cold weather, passing a restroom
- Stress incontinence
- Urinary leakage associated with exertion, lifting, coughing, sneezing
- Mixed incontinence
- Urinary leakage associated with both stress and urge incontinence
- Low bladder compliance resulting in overflow incontinence
- Continuous urinary incontinence is the continuous loss of urine
- Post-obstructive detrusor dysfunction
- The involuntary loss of urine immediately after he has finished passing urine, usually after leaving the toilet
- Mobility or cognitive impairment post stroke

TREATMENT

GENERAL MEASURES
- Bladder diaries are invaluable
- Help patients understand patterns of incontinence
- Time voiding
- Avoids significant bladder distention
- For postradical prostatectomy incontinence see Section I: Incontinence, urinary following radical prostatectomy

MEDICATION

First Line
- Anticholinergics
  - Mirabegron (25–50 mg/d)
  - Fesoterodine (4–8 mg/d)
  - Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d)
  - Darifenacin (7.5–15 mg/d)
  - Golcisatan (5–10 mg/d)
  - Eltrombopag (50 mg/d)
  - Ureteral (7.5–20 mg/d), XL 5–30 mg/d (patch twice weekly)
  - Mirabegron (25–50 mg/d)
- Ph–alpha-methyldopa
- Anticholinergic agent: Promotes detrusor muscle relaxation

**Ongoing Care**

**Prognosis**

Continence can be improved in almost all patients.

**Complications**

- Caudal hematoma
- Bladder perforation
- Skin breakdown
- Dermatitis
- Edema
- Pain
- Urethral erosion
- Obstruction

**Follow-Up**

- Monitor post-void residual volume
- Monitor function of artificial urinary sphincter
- Monitor for complications

**Patient Monitoring**

- Urodynamic monitoring
- Symptom diaries
- Compliance with medications

**Patient Resources**

**References**

INCONTINENCE, URINARY, FOLLOWING RADICAL PROSTATECTOMY

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION
- Post-prostatectomy incontinence (PPI) is a well-recognized complication of radical prostatectomy (RP) whether performed open (perineal retroperitoneal) or laparoscopically with or without robotic assistance.
- The definition of continence following RP in the literature varies widely, with the strictest definition of continence being no pads used.

EPIDEMOLOGY
Incidence
- The incidence of PPI depends on the interval of time following surgery, the definition and methodology for assessing continence, and the experience of the surgeon.
- The overwhelming majority of men have some degree of PPI immediately after catheter removal.
- If PPI is defined as no pads/small protective pad or total control/occasional dribbling, experienced surgeons consistently report continence rates exceeding 95% at 1–2 yr after RP.
- Recent evidence suggests that PPI may improve after 2 yr.

Prevalence
- Approximately 6% of men will undergo a procedure for the management of PPI at a median of 20 mo after RP (1).

RISK FACTORS (2)
- RP (1)
- For the management of PPI at a median of 20 mo after RP.
- Approximately 6% of men will undergo a procedure for the management of PPI at a median of 20 mo after RP.
- Recent evidence suggests that PPI may improve after 2 yr.

PHYSICAL EXAM

- Observe caliber of urinary stream.
- Observe degree of pad saturation.
- Observe for skin excoriation secondary to PPI.
- Inquire if PPI is improving, stable, or deteriorating:
  - Assess the severity of LUTS.
  - Determine the severity of PPI by: Number of pads, degree of bother, and frequency of incontinence episodes.
  - Assess the severity of UTS.

DIAGNOSIS

HISTORY
- Assess the severity of UTS and incontinence preoperatively.
  - The International Prostate Symptom Score (IPSS).
- Inquire about the use of α-blockers because these agents may exacerbate PPI.

- Ascertain if the PPI is exacerbated by physical activity.
- Determine the severity of PPI by: Number of pads, degree of bother, and frequency of incontinence episodes.

PHYSICAL EXAM

- Observe degree of pad saturation.
- Observe degree of incontinence when transferring from the sitting to standing position.
- Observe caliber of urinary stream.

DIAGNOSTIC TESTS & INTERPRETATION (C)

- Lab
  - Urinalysis to exclude urinary tract infection

- Imaging
  - Sonographic post-void residual (PVR)
  - Uroflowmetry
  - Pressure flow study is useful for evaluating a possible obstructive anastomotic stenosis

DIFFERENTIAL DIAGNOSIS

- None

- Pathologic Findings

- General Measures

- Voiding before strenuous activity
- Limitation of fluid intake
- Avoid drugs that may cause urinary retention
- Encourage Kegel exercises—may accelerate continence recovery

MEDICATION

- First Line
  - α- Blockers generally not effective for SUI
- Inhibit α-blockers
  - Limitation of fluid intake
- Avoid drugs that may cause urinary retention
- Encourage Kegel exercises—may accelerate continence recovery

- Second Line
  - Oxybutynin, tolterodine, darifenacin, solifenacin, fesoterodine, trospium
  - Anticholinergic agents may improve PPI secondary to DI

- Associated Conditions
  - Detrusor instability (DI)/Overactive bladder (OAB)
  - Prevention
    - Detrusor instability (DI)/Overactive bladder (OAB)
    - Stress urinary incontinence
    - Overflow incontinence
    - Mixed incontinence

- Median

- Minimum

- Maximum

- Normal

- Pathologic Findings

- None

- Pathologic Findings

- General Measures

- Voiding before strenuous activity
- Limitation of fluid intake
- Avoid drugs that may cause urinary retention
- Encourage Kegel exercises—may accelerate continence recovery

- Medication

- First Line
  - α-Blockers generally not effective for SUI
- Inhibit α-blockers
  - Limitation of fluid intake
  - Typical off-label starting dose is 25–50 mg PO QHS
- Anticholinergic agents may improve PPI secondary to DI
  - Options include: Oxybutynin, trospium, darifenacin, solifenacin, fesoterodine, trospium
Periurethral bulking agents (buline–pseudaldehyde cross-linked collagen/polyethylene/polyanhydride) are costly; they require multiple injections and have limited durable success in this setting.

**Surgery/Others Procedures**
- Surgical intervention should not be pursued until at least 1 yr post-prostatectomy because of the temporal improvements in the condition.
- Surgical intervention should not be contemplated at 1–2 yr if there is evidence of progressive improvement.
- imperative to exclude anastomotic stricture and DI before embarking on surgical correction of SUI.
- Surgical options:
  - Fistulae surgical procedure is dictated by severity of PPI.
  - More severe cases best managed with an artificial urinary sphincter (AUS).
  - In many cases, surgery achieves marked improvement in PPI but some degree of SUI may persist.
  - Male slings.
  - Artificial urinary sphincter (AUS).

**ADDITIONAL TREATMENT**

**Radiation Therapy**
Although there is no role in the treatment of PPI, data suggest that radiation administered in the adjuvant setting following RP may limit resolution of continence particularly if the radiation is administered before continence returns.

**Additional Therapies**
- Unilateral dissection should be performed if evidence of bladder outlet obstruction and anastomotic stenosis.
- Transurethral excision of the stricture may be required if stricture recurs despite multiple dilation(s).
- In Europe duloxetine, a serotonin-norepinephrine reuptake inhibitor is approved for stress urinary incontinence (US approval is only for neuropathic pain and depression).

**Complementary & Alternative Therapies**
Biofeedback may have a role in selected patients in strengthening pelvic musculature.

**ONGOING CARE**

**PROGNOSIS**
- The overwhelming majority of men will spontaneously regain urinary continence following RP.
- The small subset of men with persistent SUI will improve, providing the appropriate surgical procedure is performed.
- The worst prognosis exists for cases with severe fixative anatomic structures (bladder neck contractures) who must be made totally continent with subsequent placement of an AUS.
- PPI secondary to DI likely to improve with anticholinergic agents.

**COMPLICATIONS**
- Sexual issues.
- Diminished self-esteem:
  - Limitation of physical activity.
  - Withdrawal from sexual activity.
  - Complications of treatment for PPI.

**FOLLOW-UP**

**Patient Monitoring**
- Pad use.
- Impact of PPI on quality of life.

**Patient Resources**
http://www.webmd.com/urinary-incontinence-
.

**REFERENCES**

**ADDITIONAL READING**
- See Also (Topic, Algorithm, Media)
  - Bulking Agents, Injectable
  - Incontinence, Urinary, Adult Male
  - Stress Urinary Incontinence, Male

**CODES**

**ICD9**
- 597.39 Other urinary incontinence.
- 997.5 Urinary complications, not elsewhere specified.

**ICD10**
- N39.498 Other specified urinary incontinence.
- N99.90 Other postprocedural complications and disorders of GU sip.

**CLINICAL/SURGICAL PEARLS**
- Post prostatectomy incontinence (PPI) is very common, with the vast majority (95%) resolving 6–12 mo postoperatively.
- Kegel exercises should be instituted immediately after catheter removal postoperatively.
- It is crucial to determine the exact pattern of urinary leakage.
- If conservative measures fail, treatment for both stress SUI requires surgery.
- Type of surgery is dictated by severity of SUI.
INCONTINENCE, URINARY, PEDIATRIC
Steve J. Hodges, MD
Anthony Atala, MD

DESCRIPTION
Normal urinary control occurs in stages:

- Constipation plays a major role in urinary continence
- Delayed voiding/defecation lead to bladder overactivity, constipation
- Bladder overactivity/constipation compounded by dyspnea of pelvic floor, with failure to relax pelvic floor completely with emptying

ASSOCIATED CONDITIONS
- Family history of enuresis
- Developmental delay
- Urinary tract anomalies
- Spinal dysraphism

Prevalence
- Day or night wetting occurs in up to 25% of 4–6 yr old children
- At 12 yr of age 4% of children are enuretic at least once a week, at 15 yr old it is 2%
- Enuresis is 3–4 times more common in boys than girls

HISTORY
- Child’s sex—bedwetting is more common in boys, daytime incontinence more common in girls
- Age at onset
- Interestingly, part of the time children get bedwetted because they have a low bladder capacity (60 cc at birth; 35 cc by 12 yr old)
- History of UTI; Functional constipation?

PHYSICAL EXAM
- Orifice rule out spina bifida, rule out occult infection

DIAGNOSIS
Incontinence in the presence of an abnormal back exam may signal a neurologic abnormality

GENERAL PREVENTION
- Aggressively prevent and treat constipation
- Ensure an environment where children are not delayed voiding/defecation lead to bladder overactivity, constipation
- Delayed voiding/defecation lead to bladder overactivity, constipation
- Bladder overactivity/constipation compounded by dyspnea of pelvic floor, with failure to relax pelvic floor completely with emptying

DIAGNOSTIC TESTS & INTERPRETATION
- Urinalysis
- Neutrophic glomerulonephritis
- Hypertension
- Microscopic hematuria
- Proteinuria
- Glucosuria
- If any of above discovered, require thorough evaluation and treatment
- Urine culture if UA shows signs of infection

Imaging
- KUB to rule out spina bifida, rule out occult infection
- Renal US to evaluate for normal GU anatomy
- VCUG only needed in the setting of palpable UI or any UI in boys, hydro-nephros allow evaluation of urethra in males
- MR urography may be needed when concerned for ectopic ureter
- Renogram rarely needed to evaluate for urinary obstruction, renal function

Pathologic Findings
- Urine—urine in vaginal vault or labial adhesions in girls
- Ecstatic perineal offsprings can be cause of constant wetness in girls
- Recanal exam to rule out rectal stool, evaluate normal sensation and tone
- Neurologic exam
- Measure or observe urinary stream for force, caliber, straining, duration (may obtain flow/PVR)

NOTES
GENERAL MEASURES

- Need KUB and renal/bladder US, urodynamics
  optional

- Other pediatric bladder disorders:
  - Lazy Bladder syndrome (incontinent voider)—rare
    voids, 2–3 + a day, may have infections, associated with constipation
  - Bladder overactivity—typically associated with delayed voiding and constipation, typified by
    unblended bladder contraction with no neurologic lesion

- Hinman-Allen syndrome—nonneurogenic
  neurogenic bladder, may be due to constipation as
  well

- Daytime frequency syndrome—frequent urination
  in a child with no other identifiable abnormalities, usually do have constipation on KUB

- Giggle Incontinence—rare form of incontinence
  where wetting only occurs with laughing, may be
  centrally mediated (brain), treated with Ritalin

DIFFERENTIAL DIAGNOSIS

- Structural Incontinence:
  - Ectopic ureter
  - Ectopic ureter
  - Spinal Dysraphism

- Neurogenic:
  - Anorectal malformation, caudal tumor
  - Intraventricular pterygium
  - Myelodysplasia
  - Occult dysplasia
  - Sacral agenesis, spinal cord trauma, myelitis
  - Tight retro peritoneal, distal syrinx
  - Isolated nocturnal enuresis: Constipation, sleep
    arousal disorder, nocturnal polyuria
  - Complicated incontinence:
    - Giggle Incontinence
    - Hinman-Allen syndrome
    - Lazy Bladder syndrome
    - Overactive Bladder

SUPPORTIVE MEASURES

- Perineal hygiene—voiding positioning
- Behavioral measures—timed voiding, constipation
- Drainage—physical therapy to relax external
  sphincter
- Des—avoid bladder irritant, caffeine
- Personal hygiene—voiding positioning

MEDICATION

First Line

- Treat UTI if present

- Overactive bladder
  - Anticholinergic medications
    - Oxybutynin: Safety and efficacy of oxybutynin
      chloride administration have been demonstrated
      for pediatric patients 5 yr of age and older
      - Tobsimone (off label in children)
    - Consider an antagonist (neurypage off label in
      children)
  - Constipation
    - PEG 3350, enemas or suppositories, Senna
      laxatives, fiber supplements

SURGERY/OTHER PROCEDURES

- Structural—alleviate structural cause of
  incontinence
  - Neurogenic: low compliance bladder may require
    enterocystoplasty, urethral dilation, neural
    stimulation, botulinum toxin injection
  - Overactive Bladder: may benefit from neural
    stimulation, botulinum toxin injection in bladder
    or sphincter, cysto urethral dilation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Aggressive constipation management for severe cases may require chronic enemas or antegrade continence
enema (ACE) creation

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most patients do resolve over time as they grow, and gain more mature toileting habits
- Severe cases may lead to pelvic floor disorders (such as pelvic pain syndrome, dyspareunia in future, so
  aggressive therapy indicated

FOLLOW-UP

Patient Monitoring

- Follow-up for observation of progress, adjusting medications as needed
  - Structural and neurogenic causes need routine
    evaluations to rule out upper tract injury and
    monitor progress

Patient Resources

- National Kidney and Urologic Diseases
ASSOCIATED CONDITIONS

Pretesticular:
- Hypogonadotropic hypogonadism: Low follicle stimulating hormone (FSH), luteinizing hormone (LH), and testosterone (T) with normal prolactin
- Hypothyroidism
- Medication use: See Risk Factors
- Elevated estradiol from moxibustion, tumors, or hepatic dysfunction
- Kallmann syndrome: X-linked, absent GnRH sensation, absent puberty, anosmia
- Pituitary or cranial trauma, infection, or tumor
- Hypogonadism: Prostatic inhibition of action on Leydig cells. Brain MRI to evaluate for macroprolactinemia (<1 cm)
- Macroprolactinemia: Refer for possible resection
- Microprolactinoma: May respond to dopamine agonist (11Tianeptine, Cabergoline, 2nd Biocytostatic)

Testicular:
- Varicocele: 15% of all men, 35–40% of men with primary infertility, 70–80% of men with secondary infertility
- Bilateral cryptorchidism, testicular injury, heavy alcohol use, recreational drugs (marijuana, cocaine), surgical history, medications, and other medical illnesses
- 46,XX with male phenotype: No spermatogenesis, donor sperm/adoption
- Androgenization disorders: Defects in synthesis of T, androgen receptor, and 5α-reductase
- Y microdeletions: AZFa, b and c: See Genetics
- 46,XY with male phenotype: Fertility factors: X-linked, autosomal, postpubertal mumps orchitis
- Sertoli-cell only syndrome: Absent germ cells
- Tuberculosis: Spermatozoa harbored at a certain stage

Genetic/chromosomal factors:
- Klinefelter: 47,XXY, small, firm testes; often azoospermic, however, spermatozoa (47,XY,46,XY) allows spermogenesis. Up to 60% have sperm found from TESA
- Noonan syndrome: AZFa (1–5% NOA) predicts TESA failure
- AZFa (1–5% NOA) predicts TESA failure
- AZFa (11% NOA) best prognosis, can be oligospermic, if azoospermic 2/3rd s have sperm on TESA

PATHOPHYSIOLOGY

3 categories:
- Pretesticular: Endocrine abnormality
- Testicular: Abnormal sperm production
- Posttesticular: Abnormal sperm transport
MEDICATION

DIFFERENTIAL DIAGNOSIS

Diagnostic Procedures/Surgery

 Pathologic Findings
  - Spermatozoa—Use in azoospermic patients with palpable vasa and low-volume ejaculate.
  - Seminal vesicle dilation (normal < 2 cm) indicative of EDO.
  - Scrotal ultrasound—only used in patients with NOA or severe oligospermia (< 5 million sperm/mL).
  - Consider 1 chromosome microdeletion testing if azoospermic

Imaging

  - Testicular ultrasonography—Use in azoospermic patients with palpable vasa and low-volume ejaculate.
  - Seminal vesicle dilation (normal < 2 cm) indicative of EDO.
  - Scrotal ultrasound—only used in patients with NOA or severe oligospermia (< 5 million sperm/mL).
  - Consider 1 chromosome microdeletion testing if azoospermic

TREATMENT

  - Assisted Reproductive Technologies (ARTs), Intrauterine insemination (IUI), In Vitro Fertilization (IVF) and Intracytoplasmic Sperm Injection (ICSI)
  - Additional Therapies
    - N/A
    - Counselling and CFTR mutation testing
    - Coenzyme Q10 is used
    - 20-30% pregnancy rates per cycle

ONGOING CARE

  - Pregnancy rates are highly dependent on the age of the female partner
  - MicroTESE for NOA: 67% sperm-retrieval rate
  - MicroTESE: Performed for NOA, superior to other sperm-retrieval techniques with 20-30% improvement in yield up to 67%

COMPLICATIONS

  - MicroTESE: Vasectomy, or vasectomy/lymphedema should be performed by microsurgical specialist.
  - OA, if patient does not desire reconstruction or it is not possible. TESAs, percutaneous or microsurgical epididymal sperm aspiration (PESA or MESA)
  - Varicocelectomy: Recommended for men with infertility, palpable varicocele, abnormal semen parameters, elevated FSH, and female partner with normal/potentially correctable infertility (A)[A]
  - Transurethral resection of ejaculatory ducts: For EDO
  - Neurostimulatory ejaculation: Men with spinal cord injury may be able to retrieve sperm via ejaculation with penile vibratory stimulation or, in the event of injury may be able to retrieve sperm via ejaculate

ADDITIONAL READING

  - See Also (Topic, Algorithm, Media)
    - Assisted Reproductive Technologies (ARTs)
    - Ejaculatory Disorders
    - Intrauterine insemination (IUI), In Vitro Fertilization (IVF) and Intracytoplasmic Sperm Injection (ICSI)

CLINICAL/SURGICAL PEARLS

  - Testis biopsy is rarely indicated in the evaluation of male infertility.
PATHOPHYSIOLOGY
- Population × prevalence greater than that of the general
- Adult female 1st-degree relatives of IC patients have a predisposition
- No known risk factors beyond a possible genetic

RISK FACTORS
- Ranges from 1.6 to 2,600 per 100,000 people
- Incidence
- Prevalence
- Incidence and prevalence vary widely

GENERAL PREVENTION
- Specific prevention strategies, although dietary changes and medical therapy may mitigate symptom
general/spinal anesthesia:
- Findings may include: Glomerulations (small foci
inflammation
- “Nonclassic”: No inflammatory lesions identified
- “Classic”: No inflammatory lesions identified upon
cystoscopy
- Median age of onset 30–40 yr
- Female: Male 5:1
- 5–10% of patients have Hunner lesions

DIAGNOSIS
- No definitive prevention strategies, although dietary
cystoscopy (formerly known as Hunner ulcer)
- “Nonclassic”: No inflammatory lesions identified
- Bimanual exam with palpation of bladder, urethra,
- Potassium sensitivity testing (KCl test):
- Cystoscopy with hydrodistention under
- Focused neurologic exam
- Bladder Pain/Interstitial Cystitis Symptom Score
- O’Leary-Sant Symptom and Problem Score
- Symptom evaluation with voiding diary
- PUF (Pelvic Pain & Urgency/Frequency)
- Visual analog scale (pain score)
- Urinary frequency, urgency, nocturia
- Urinary frequency based upon need to decrease
- Pain associated with bladder filling and/or emptying
- Promontory flare
- Abdominal/pelvis pubic pain
- Urinary frequency, urgency, nocturia
- Urinary frequency based upon need to decrease
- Bladder effects of chemotherapy
- Bladder outlet obstruction/urinary retention
- Increased sensitivity (pain) on filling and

PHYSICAL EXAM
- General: Abdominal exam to assess for supra-pubic
- Painful bladder syndrome
- Fibrinopyla
- Chronic fatigue syndrome
- Genital herpes
-外生殖器検査
- Digital rectal exam with palpation of prostate and
- External genitalia exam

ASSOCIATED CONDITIONS
- Multiple pelvic floor: Most commonly identified
comorbid condition
- Irritable bowel syndrome
- Fibromyalgia
- Chronic fatigue syndrome
- Multiple allergies
- Sjogren syndrome
- Chronic headaches
- Depression/neurogenic disorder
- In females: Vulvodynia, endometriosis
- In males: Chronic prostatitis/chronic pelvic pain
syndrome, BPH, prostate cancer

DIAGNOSTIC TESTS & INTERPRETATION
- Lab: Urinalysis and urine culture
- Urine cytology in high risk groups

Imaging
- No recommended imaging for the diagnosis of IC/PBS

Diagnostic Procedures/Surgery
- Urodynamics:
- Normal detrusor function on cystometry, may have
increased sensitivity (pain) on filling and
decreased capacity.
- Late stages of “classic” IC/PBS may be associated
with significant decrease in capacity and bladder
dyness.
- Cystoscopy:
- Used selectively to exclude other bladder
pathology and identify Hunner lesions
- Cystoscopy with hydrodistention under
general/spinal anesthesia:
- Findings may include: Glomerulations (small foci
inflammation
- Hunner lesions, decreased
anesthetic capacity, mucosal tears, low sensitivity
and specificity
- Hunner lesion (ulcer) is described as circumscript,
reddened area with small vessels radiating toward a
central scar. Fibrin deposit/coagulum can be
attached to this area. With bladder distention the
site ruptures with petechial blood oozing from the
lesion and mucosal margins (5)
- Potassium sensitivity testing (KCl test):
- Low sensitivity and specificity, positive result
provides pain
- Residual urination in males
Pathologic Findings
- Histologic findings can vary widely and are
truly pathognomonic:
- Bladder biopsy:
- Indicated only to rule out other disease processes
- Hunner lesions demonstrate pan-mural
inflammation

DIFFERENTIAL DIAGNOSIS
- Bacterial cystitis
- General bladder cancer (including CIS)
- Bladder effects of chemotherapy
- Bladder outlet obstruction/urinary retention
- Bladder/lower urinary tract
- Genital herpes

INTERSTITIAL CYSTITIS (IC)/PAINFUL BLADDER SYNDROME (PBS)
Nikhil Waingankar, MD
Sonia Bahmani, MD
Robert M. Moldwin, MD, FACS

BASICS
DESCRIPTION
- Interstitial cystitis (IC) or Painful Bladder Syndrome
(PBS) is an unpleasant sensation (pain, pressure,
discomfort) perceived to be related to the bladder,
associated with lower urinary tract symptoms (LUTS)
for more than 6 wk duration, and in the absence of
other identifiable causes (1,2)
- 90% of patients also complain of frequency
(>10–12 × daily), nocturia is common
- 8% complained of constipation/persistent urgency
- Dysuria & unusual:
- Symptoms can be associated with a wide range of
diseases (see “Differential Diagnosis”)
- Two forms of IC/PBS:
- “Classic”: Associated with Hunner lesions on
cystoscopy (formerly known as Hunner ulcer)
- “Nonclassic”: No inflammatory lesions identified
upon cystoscopy

Epidemiology (3)
- Incidence and prevalence vary widely

Incidence
- 0.6–1.6 per 100,000 people

Prevalence
- Ranges from 1.6 to 2,600 per 100,000 people

Risk Factors
- No known risk factors beyond a possible genetic
predisposition

Genetics
- Adult female: 1st-degree relatives of IC patients have a
prevalence 17× greater than that of the general
population

Pathophysiology
- Multifactoral etiology with a number of proposed
mechanisms:
- Epithelial permeability
- Antiproliferative factor
- Host cell activation
- Neurogenic inflammation
- Infectious
- Autoimmune
- Urinary abnormality: Toxic, allergic, immunologic

ASSOCIATED CONDITIONS
- Muscle of pelvic floor: Most commonly identified
comorbid condition
- Irritable bowel syndrome
- Fibrinopyla
- Chronic fatigue syndrome
- Multiple allergies
- Sjogren syndrome
- Chronic headaches
- Depression/neurogenic disorder
- In females: Vulvodynia, endometriosis
- In males: Chronic prostatitis/chronic pelvic pain
syndrome, BPH, prostate cancer

GENERAL PREVENTION
- No definitive prevention strategies, although dietary
changes and medical therapy may mitigate symptom
flares

DIAGNOSIS
HISTORY
- IC patients: 10× more likely to have childhood
bladder problems
- Symptoms unrelated to any identifiable cause
- “Classic” IC/PBS is an unpleasant sensation (pain,
pressure, discomfort) perceived to be related to the
bladder, associated with lower urinary tract symptoms
(LUTS) for more than 6 wk duration, and in the absence of
other identifiable causes (1,2)

Lab:
- Urinalysis and urine culture
- Urine cytology in high risk groups

Imaging
- No recommended imaging for the diagnosis of IC/PBS

Diagnostic Procedures/Surgery
- Urodynamics:
- Normal detrusor function on cystometry, may have
increased sensitivity (pain) on filling and
decreased capacity.
- Late stages of “classic” IC/PBS may be associated
with significant decrease in capacity and bladder
dyness.
- Cystoscopy:
- Used selectively to exclude other bladder
pathology and identify Hunner lesions
- Cystoscopy with hydrodistention under
general/spinal anesthesia:
- Findings may include: Glomerulations (small foci
inflammation
- Hunner lesions, decreased
anesthetic capacity, mucosal tears, low sensitivity
and specificity
- Hunner lesion (ulcer) is described as circumscript,
reddened area with small vessels radiating toward a
central scar. Fibrin deposit/coagulum can be
attached to this area. With bladder distention the
site ruptures with petechial blood oozing from the
lesion and mucosal margins (5)
- Potassium sensitivity testing (KCl test):
- Low sensitivity and specificity, positive result
provides pain
- Residual urination in males

Pathologic Findings
- Histologic findings can vary widely and are
truly pathognomonic:
- Bladder biopsy:
- Indicated only to rule out other disease processes
- Hunner lesions demonstrate pan-mural
inflammation

DIFFERENTIAL DIAGNOSIS
- Bacterial cystitis
- General bladder cancer (including CIS)
- Bladder effects of chemotherapy
- Bladder outlet obstruction/urinary retention
- Bladder/lower urinary tract
- Genital herpes
INTERSTITIAL CYSTITIS (IC)/PAINFUL BLADDER SYNDROME (PBS)

- Overactive bladder
- Pelvic floor muscle dysfunction
- Pelvic nerve entrapment
- Radiation cystitis
- Female:
  - Cervical/vaginal cancer
  - Urethral diverticulum
  - Pelvic organ prolapse
  - Endometriosis
  - Vaginal candidiasis
- Male:
  - BPH, prostate cancer, prostatitis

TREATMENT

GENERAL MEASURES
(Adapted from AUA guidelines 2011) (6)

- Patients should be aware that no single treatment has been found effective
- 1st line
  - Stress reduction
  - Exercise
  - Warm baths
  - Topical lidocaine
  - Biofeedback
  - Avoidance of spicy foods, caffeine, alcohol, artificial sweeteners, acidic beverages
- 2nd line
  - Pelvic floor physical therapy
  - Multimodal pain management
  - Amitriptyline
  - Clonidine
  - Hydroxyzine
  - Pentosan polysulfate
- 3rd line
  - Cystoscopy with hydrodistention (low pressure/short duration)
  - Fulguration of Hunner lesions
  - Submucosal injection of Hunner lesions with triamcinolone
  - Neurostimulation
  - Intravesical: 4% alkalinized lidocaine
  - Intravesical: 50% DMSO
  - Intravesical instillation: Author’s preferred
  - Intravesical “cocktail”: Lidocaine, gentamicin, heparin, artificial sweetener, acidic beverages

ADDITIONAL READING

CODES

ICD9
- 598.31 Chronic interstitial cystitis
- 959.30 Hematuria, unspecified
- 768.41 Urinary frequency

ICD10
- N30.10 Interstitial cystitis (chronic) without hematuria
- N30.11 Interstitial cystitis (chronic) with hematuria
- R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARLS

- IC/IC/PBS is more common in women than in men.
- This is primarily a clinical diagnosis based upon the presence of characteristic symptoms and the exclusion of other causes.

PEARLS

- Chronic interstitial cystitis/bladder pain syndrome is a chronic, refractory, distressing condition that requires an interdisciplinary approach.
LATEX ALLERGY, UROLOGIC CONSIDERATIONS

Ahmad H. Bani-Hani, MD, FAAP, FACS

RISK FACTORS

Prevalence

DESCRIPTION

- Localized or systemic reaction to latex, a natural substance from the sap of the rubber tree, Hevea brasiliensis (TA-A).
- Latex is a common ingredient in many medical and dental products (eg, bladder catheters, blood pressure cuffs, face masks, gloves, endotracheal tubes, IV infusion sets, etc.).
- Patients with spina bifida or congenital urogenital abnormalities have the highest risk.
- Mild forms include pruritus and swelling. The most severe form of allergic reaction is anaphylaxis. A severe, life-threatening, generalized or systemic hypersensitivity reaction characterized by rapidly developing life-threatening airway and/or breathing abnormalities may occur.

EXPOSURE TO MULTIPLE SURGERIES: 1/3–2/3 OF CHILDREN

ALERT

- Should report their allergies prior to any medical procedures.
- Should avoid latex-containing products.
- Should wear a medical alert bracelet indicating latex allergy.

GENETICS

- Genetic factor might be indicated.
- Latex allergy is less frequent in adults with spinal cord injury and multiple surgical procedures than in children with similar conditions.
- Interleukin-13 (IL-13) and IL-18 promoter polymorphisms more likely to be found in healthcare workers in comparison to nontoxic controls or patients with anorectal/urologic malformations.

PATHOPHYSIOLOGY

- Presentation with Hevea latex allergens is prerequisite to initiate an allergic response.
- A number of proteins found in the cytoplasm of H. brasiliensis are known potent allergens that can elicit human IgE antibody, leading to sensitization in exposed patients and a spectrum of allergic reactions upon subsequent exposure (4,24).
- Symptoms of delayed (type IV) hypersensitivity usually develop within 1–2 days of exposure. Immediate (type I) hypersensitivity causes symptoms within minutes of exposure.
- Immediate hypersensitivity reactions to latex (type I) are caused by cross-linking of latex protein-specific IgE antibody with mast cells and basophils.
- Cross-reactivity between various proteins is responsible for the clinical associations between latex allergy and allergic responses to a number of fruits and vegetables.
- Type I (1-today-mediated type), delayed hypersensitivity reaction can occur and usually manifest as contact dermatitis 24–96 hr after exposure.

GENERAL PREVENTION

- Facility:
  - Establishment of a latex-safe environment should be a priority for institutions by replacing all Hevea latex–containing products with non–Hevea-based synthetic products or powder-free latex products.
  - Synthetic alternatives to rubber include butyl rubber, a petrolatum-based product with no allergenic protein, neoprene, and copolymers of butadiene and acrylonitrile.
  - Non–Hevea source of natural rubber is the guayule plant (Ficus). Guayule-based products pose no risk to individuals allergic to Hevea latex and is approved by the Food and Drug Administration (FDA).
  - Individuals with latex allergy:
    - Should wear a medical alert bracelet indicating latex allergy.
    - Should be encouraged to have self-injectable epinephrine if they have a clinical history of systemic reaction to latex.
    - Should avoid latex-containing products.
    - Should report their allergies prior to any medical or surgical procedure

DIAGNOSIS

HISTORY

- Detailed clinical history of allergic reactions that are temporarily associated with exposure to Hevea latex–containing products (eg, prior history to anaphylaxis and/or intraoperative shock, itching, redness, or swelling following dental, sexual, or pelvic exam; itching or swelling with condoms, diapers, or latex sexual aids).
- Detailed history of associated risk factors: Healthcare workers, hair dressers, rubber handling, eczema/hay fever; multiple surgeries, food allergies, etc.
- 30–80% of patients with latex allergy also have food allergy.
- Allergic symptoms can include the following symptoms:
  - Angioedema
  - Dizziness
  - Pronus
  - Rhinitis
  - Tearing
  - Swelling at the site of contact
  - Abdominal cramps
- In the most extreme cases, anaphylaxis can develop

ALERT

- Use caution when examining any child for dysfunctional voiding especially if the child has neurologic symptoms or suspected spina bifida.

PHYSICAL EXAM

- Use nonlatex exam gloves.
- Use latex-free skin test if no history of previous latex exposure.
- Use nonlatex minocycline (eg, hydrocortisone).
- Use latex-free, neoprene, or nitrile latex-free gloves

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine urinalysis lab studies (blood, gas, etc.) if during acute anaphylaxis

IMAGING

- N/A

DIAGNOSTIC PROCEDURES/SURGERY

- These are performed on a routine basis and not during an acute event
- Pre-procedure skin test:
  - Skin prick test:
    - Extracts of Hevea latex, at least 3
    - Commercial extracts are available
    - Test involves performing a puncture with a lancet device through a drop of latex extract at sequential concentrations ranging from 0.001–1 mg/mL of protein
    - Results are read after 15 min and compared with the positive histamine and negative saline controls
  - Small risk of anaphylaxis

222
First Line

- **For the management of anaphylaxis**
  - **Removal latex source**
  - **Basic life support principles (Airway, Circulation, Breathing)**
  - **Injectable epinephrine in severe anaphylaxis:**
    - 0.3–0.5 mL of a 1:1000 solution \( \text{HCl} \) (adult)
    - 0.15–0.3 mL of a 1:1000 solution \( \text{HCl} \) (children)

- **EpiPen, Adrenaclick (0.3 mg) in adults**
- **Epinephrine autoinjectors:**
  - **Avoid foods with latex cross-reactivity:**
  - **Anaphylactic shock**
  - **Cardiogenic shock**

**CODES**

- **ICD9**
  - Z91.040 Latex allergy status
  - Q64.9 Congenital malformation of urinary system, unspecified
  - 753.9 Unspecified anomaly of urinary system
  - V15.07 Allergy to latex

- **ICD10**
  - N31.9 Haemorrhagic dysmenorrhoea of bladder, unspecified
  - O64.9 Congenital malformation of urinary system, unspecified
  - Z91.040 Latex allergy status

**CLINICAL/SURGICAL PEARLS**

- **Natural rubber latex allergy is caused by sensitization to proteins found in H. brasiliensis, the rubber tree.**

- **The highest prevalence of latex allergy (up to 68%) is in patients with spina bifida or congenital urogenital abnormalities.**

- **The mainstay of management of latex allergy is avoidance of latex products as there is no cure for latex allergy.**
LIBIDO, DIMINISHED, FEMALE
Sandip P. Vasavada, MD, FACS
Bradley C. Gill, MD, MS

LIBIDO, DIMINISHED, FEMALE

BASICS
DESCRIPTION
- Diminished libido, low sexual drive, or hyposexuality are defined by a lack of desire for sexual activity.
- Hypoactive sexual desire disorder or subjective sexual arousal disorder may be implicated.

EPIDEMIOLOGY
Incidence
- More common with advancing age and especially following menopause
- A congenital syndrome may be causative at a young age
Prevalence
- Estimated prevalence of 25–75% of women varies by study sample and assessment

RISK FACTORS (1)
- Low testosterone (physiologic or iatrogenic)
- Advanced age
- Menopause (physiologic or iatrogenic)
- Pelvic fluid disorder (incontinence or prolapse)
- Physical or psychological trauma (sexual assault, physical abuse, or verbal abuse)
- Pregnancy (multifactorial per hormonal, emotional, and physical changes)

Genetics
- Early menopause may be implicated

PATHOPHYSIOLOGY (2,3)
- Testosterone drops 50% from age 30 to 60 years
- Estrogen can increase sex hormone-binding globulin concentrations and lower free testosterone.
- Progesterone may lower mood and decrease sex drive as seen with some contraceptives.
- Full-time stimulating and leveling hormone reduction by contraceptives lowers androgen production.
- Sex steroid level alterations from certain antidepressants can decrease sex drive.

ASSOCIATED CONDITIONS
- Vaginal atrophy
- Congenital syndromes
- Posttraumatic stress disorder (prior physical or psychological trauma)

GENERAL PREVENTION
- Exercise, balanced diet, Healthy Lifestyle

DIAGNOSIS

HISTORY
- Details of low libido
  - Acquired or lifelong problem
  - Always or intermittently present
  - With or without sexual partners
  - After a new diagnosis or procedure
  - Following use of a new medication
  - Association with life events
  - Reproductive information
    - Age of menarche or onset of menstruation
    - Progesterones and deliveries
  - Contraception use and type
  - Infertility and treatment
  - Other sexual information
    - Sexually transmitted infection
    - Pain or discomfort with sexual activity
    - Problems with sexual function of the partner
  - Current or prior abuse
    - Sexual
    - Verbal or physical
  - Symptoms of androgen insufficiency
    - Decreased androgen
    - Decreased free testosterone or increased sex hormone–binding globulin concentrations
    - Signs of androgen insufficiency
  - Bone loss, decreased muscle mass, less strength
  - Memory changes and altered cognitive function
  - Other endocrine disorders
    - Hypothyroidism
    - Cushing syndrome
    - Diabetes
  - Urinary conditions
    - Urinary incontinence or fecal incontinence
  - Pelvic organ prolapse
  - Medications
    - Oral contraceptives, estrogens, progestins, gonadotropin-releasing hormone agonists
    - Antidepressants, anticonvulsants, antiepileptics, psychotropics
    - Alpha-blockers, antihypertensives, anticholinergics, antidiabetes, antihistamines
    - Statins, nectarin
  - Chronic medical conditions
    - Hypothyroidism
    - Substance abuse

PHYSICAL EXAM
- Assessment of congenital sexual characteristics
  - Breast development
  - Axillary hair
  - Signs of endocrinologic disorder
  - Cushingoid appearance
  - Hypothyroid skin and hair changes
  - Diabetic neuropathy
  - Visual inspection of the external genitalia
    - Distribution of pubic hair
  - Ulcerations, pustules, discharge, or bleeding
  - Prominence of urethra, vagina, or cervix
  - Speculum exam
    - Vaginal discharge, moisture, thinning, or erosion
  - Ulcerations, pustules, discharge, or bleeding
  - Cytoscopy, rectoscopy, or endoscopy
  - Vaginal wall masses
  - Palpation of the external genitalia, vaginal sidewalls, pelvic floor muscles, ovaries, and ovaries
  - Urethral or vaginal sidewall masses
  - Surgically placed foreign bodies
  - Pelvic floor muscle tension, spasm, or tenderness
  - Cervical motion, vacuum, or adnexal tenderness
  - Vaginal cut-out mass or tenderness

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Estrogens: Estradiol and estrene
  - Androgens: Dehydroepiandrosterone, androstenedione, testosterone, and dihydrotestosterone
  - Proteins: Sex hormone–binding globulin (SHBG)
  - Androgen: Free testosterone
  - Other tests: Gonadotropin-releasing hormone agonists
  - Imaging
    - Brain magnetic resonance imaging to assess the hypothalamus and pituitary gland

DIFFERENTIAL DIAGNOSIS
- Hypothalamic
  - Decreased free testosterone or increased sex hormone–binding globulin
  - Decreased estrogen
  - Hypogonadotropic hypogonadism
- Adrenal insufficiency or adrenal suppression
  - Adrenal suppression or glucocorticoid excess
  - Hypothyroidism or hyperthyroidism
LIBIDO, DIMINISHED, FEMALE

TREATMENT

GENERAL MEASURES (1)

- Psychological
  - Hypoactive sexual desire disorder, subjective sexual arousal disorder, sexual aversion disorder
  - Sexual dysfunction in a partner
- Iatrogenic
  - Medication side effect
- Gynecologic
  - Dyspareunia, pelvic organ prolapse, sexually transmitted infection
- Urologic
  - Urinary incontinence
- Congenital syndrome

MEDICATION

First Line

- Testosterone alone or in combination has been used off-label to increase drive
  - Postmenopausal women with decreased libido who are not receiving estrogen therapy have modest success using an experimental testosterone patch delivering 300 μg/d
  - If possible elimination or replacement of medications that may reduce libido
  - Adjunctive treatment of vaginal atrophy with topical estrogen can be helpful

Second Line

N/A

SURGERY/OTHER PROCEDURES

Appropriate treatment of possibly causative medical (ie, endocrine tumor) conditions

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- Results vary with etiology and treatment for many is long-term
- Multimodal approach to any etiology should be most beneficial

COMPLICATIONS

Use of libido can result in depression, infertility

FOLLOW-UP

Patient Monitoring

- Frequent follow-up with initiation of new therapy is best with regular lab work if hormones are used.
  - If using testosterone, monitor for signs of testosterone excess (acne, hirsutism, male pattern baldness, hyperlipidemia)

Patient Resources
N/A

- Female Hypoactive Sexual Desire Disorder
- Urinary incontinence
- Vaginal Atrophy

CODES

ICD9
- 799.81 Decreased libido
- 627.2 Symptomatic menopausal or female climacteric states
- 302.71 Hypoactive sexual desire disorder

ICD10
- T52.0 Hypoactive sexual desire disorder
- N85.1 Menopausal and female climacteric states
- R68.82 Decreased libido

CLINICAL/SURGICAL PEARLS

- A good social history is essential.
- Sexual dysfunction in partners can cause this.
- Overall physical health help maintain libido.
**LIBIDO, DIMINISHED, MALE**

Daniel Box, MD
Anish K. Shah, MD

---

**BASICS**

**DESCRIPTION**
- Diminished libido (hyposexuality) is the lack of desire to engage in sexual experience.
- Hypoactive sexual desire disorder is characterized by reduced libido and interest in sexual activity causing distress in women.
- This section primarily focuses on decreased libido in men.

**EPIDEMIOLOGY**

**Incidence**
- 10–15% of men
- 20–25% of women

**RISK FACTORS**
- Therapy for prostate cancer
- Congenital absence of the testicles
- Metabolic syndrome
- Surgical injury or removal of the testicles
- Inflammatory insults to the testicles
- Congenital absence of the testicles
- Therapy for prostate cancer
- Decreased bone density/osteoporosis

**GENETICS**
- Loss of libido may be associated with some of the genetic disorders/syndromes, listed below:
  - 17α-Hydroxylyase deficiency
  - Autoimmune polyendocrine syndrome
  - Klinefelter syndrome
  - Inactivation of the tubulinizing hormone (V-Ho-receptor gene
  - Mutations of steroid 5-α-reductase gene

**PATHOPHYSIOLOGY**
- Psychological causes of diminished libido
  - Libido (sexual drive) is mediated by the cerebral cortex.
  - Psychological disturbances of all degrees, from anxiety to major psychiatric disorders
  - May be secondary to medical conditions (ie, congenital anomaly, disfiguring injury, etc.)
  - Erectile dysfunction may cause loss of libido
- Hormonal causes of diminished libido
  - Hypogonadism: Androgen deficiency, particularly testosterone, whether primary (testicular defect) or secondary to hypothalamic-hypophysary dysfunction, Cushings syndrome
  - Hypothyroidism with or without pituitary lesion (TSH)
  - Thyroid: Both hyper- and hypothyroidism can lead to diminished sexual desire

**DIAGNOSIS**

**HISTORY**
- Sexual history
  - Frequency and level of sexual desire
  - Difficulty in achieving or maintaining an erection
  - Evidence of ejaculation disorder, overall satisfaction with sexual life
  - If semen volume is normal, it is unlikely that endocrine factors are responsible for loss of libido
  - Sexual Health Inventory of Men (SHIM) score
  - History of psychiatric illness
  - Symptoms to suggest decreased testosterone: ED, decreased bone density/osteoporosis
  - History of endocrine disorder
  - Therapy for prostate cancer
  - Chronic alcoholism may result in decreased serum testosterone, testicular atrophy, and decreased libido.

**DIFFERENTIAL DIAGNOSIS**
- Determine the cause and correct, if possible.
- Identify potential medications causing libido issues.
- Psychiatric consultation/sexual function therapist
- Endocrinology consultation

**TREATMENT**

**MEDICATION**

**First Line**
- Decreased testosterone (T)
  - Hormone supplementation. For replacement dosing, see chapter on "Testosterone, decreased (hypogonadism)".
  - Patients interested in sustaining fertility. Avoid exogenous testosterone; stimulate with human chorionic gonadotropin.
  - If sexual dysfunction is identified as the cause: Phosphodiesterase inhibitors (sildenafil, tadalafil, etc.) are potentially useful 1st-line therapies
  - Bromocriptine for prolactin-secreting tumors

**Second Line**

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Serum testosterone
- Serum prolactin
- If any disturbances of the above, then serum follicle-stimulating hormone and LH
- Serum-free T4 and TSH
- Serum GH and IGF-1 (primarily in children)
- Evlauation for increased cortisol if Cushing’s is suspected

**PHYSICAL EXAM**

**DESCRIPTION**
- Diminished libido (hyposexuality) is the lack of desire to engage in sexual experience.
- Hypoactive sexual desire disorder is characterized by reduced libido and interest in sexual activity causing distress in women.
- This section primarily focuses on decreased libido in men.

**GENERAL PREVENTION**

**GENERAL MEASURES**
- Avoid exogenous testosterone, stimlate with human chorionic gonadotropin.
- If sexual dysfunction is identified as the cause: Phosphodiesterase inhibitors (sildenafil, tadalafil, etc.) are potentially useful 1st-line therapies
- Bromocriptine for prolactin-secreting tumors

**ASSOCIATED CONDITIONS**
- Erectile dysfunction (ED) and infertility may be associated with loss of libido and vice versa (2).
- Hypothyroidism
- Alcoholism
- Syndromes, listed above in the Genetics section

**DIAGNOSIS**

**HISTORY**
- Sexual history
  - Frequency and level of sexual desire
  - Difficulty in achieving or maintaining an erection
  - Evidence of ejaculation disorder, overall satisfaction with sexual life
  - If semen volume is normal, it is unlikely that endocrine factors are responsible for loss of libido
  - Sexual Health Inventory of Men (SHIM) score
  - History of psychiatric illness
  - Symptoms to suggest decreased testosterone: ED, decreased bone density/osteoporosis
  - History of endocrine disorder
  - Therapy for prostate cancer
  - Chronic alcoholism may result in decreased serum testosterone, testicular atrophy, and decreased libido.

**DIFFERENTIAL DIAGNOSIS**
- Determine the cause and correct, if possible.
- Identify potential medications causing libido issues.
- Psychiatric consultation/sexual function therapist
- Endocrinology consultation

**TREATMENT**

**MEDICATION**

**First Line**
- Decreased testosterone (T)
  - Hormone supplementation. For replacement dosing, see chapter on "Testosterone, decreased (hypogonadism)".
  - Patients interested in sustaining fertility. Avoid exogenous testosterone; stimulate with human chorionic gonadotropin.
  - If sexual dysfunction is identified as the cause: Phosphodiesterase inhibitors (sildenafil, tadalafil, etc.) are potentially useful 1st-line therapies
  - Bromocriptine for prolactin-secreting tumors

**Second Line**

---

**MARKS & SYMPTOMS**

**DIAGNOSIS**

**HISTORY**
- Sexual history
  - Frequency and level of sexual desire
  - Difficulty in achieving or maintaining an erection

**Second Line**

---
LIBIDO, DIMINISHED, MALE

SURGERY/OTHER PROCEDURES
Only useful for pituitary adenomas causing hyperprolactinemia or in cases of Cushing’s disease.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
L-arginine and yohimbine are touted but not proven

ONGOING CARE

PROGNOSIS
The prognosis is good when there is a treatable underlying cause for loss of libido. Otherwise it can be permanent.

COMPLICATIONS
Loss of libido can result in depression, infertility, and erectile dysfunction.

FOLLOW-UP
Patient Monitoring
Men treated with androgens should be followed closely with digital rectal exam and prostate-specific antigen every 6 mo.

Patient Resources

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
• Andropause (Late Onset Male Hypogonadism)
• Erectile Dysfunction
• Female Hypoactive Sexual Desire Disorder
• Testosterone, Decreased (Hypogonadism)

CODES
ICD9
• 302.71 Hypoactive sexual desire disorder
• 752.89 Other specified anomalies of genital organs
• 799.81 Decreased libidos

ICD10
• F52.0 Hypoactive sexual desire disorder
• Q55.0 Absence and aplasia of testis
• R68.82 Decreased libido

CLINICAL/SURGICAL PEARLS
• Decreased libido can be from a number of causes (medications, hormonal or psychiatric disorders, etc.).
• A thorough history (including sexual history and SHIM score) and physical exam (assessment of secondary sex characteristics and testicular volume) are critical and can often point to a diagnosis.
• It is very important to distinguish decreased libido from other disorders of sexual function (arousal, erectile dysfunction, premature ejaculation, orgasm, and sexual pain disorders) but patients can often have multiple issues simultaneously.
• Surgery is usually designated for pituitary adenomas (ie, prolactinomas), which can be found on brain MRI.
LOWER URINARY TRACT SYMPTOMS
Matthew J. Resnick, MD
David F. Penson, MD, MPH

PATHOPHYSIOLOGY
- BOO results in generation of higher bladder pressures to overcome outlet resistance.
- Bladder "remodeling," secondary to longstanding outlet obstruction results in overactive bladder syndrome, storage symptoms, and over time, decreased contractility.
- LUTS may result from numerous conditions of the central and peripheral nervous systems.
- Result in either detrusor overactivity (storage symptoms) or detrusor hypertonia (urinary retention/hydronephrosis).

ASSOCIATED CONDITIONS
Erectile dysfunction

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
- Essential to quantify LUTS for both diagnosis and treatment planning.
- Use the validated AUA Symptom Score (AUASS) often referred to as the AUA symptom index (AUSI) or International Prostate Symptom Score (IPSS) (1–7 mild; 8–19 moderate; 20–35 severe).
- Attention should be paid to nature (obstructive/storage) and duration of LUTS.
- Consider voiding diary (frequency/volume charts) if the patient is unable to elaborate the nature of his or her symptoms.
- Elicit history of prior urinary tract infection or prostatitis.
- Elicit history of prior hematuria (gross or microscopic).
- Elicit history of prior urologic/pelvic surgery.
- Prior lower urinary tract intervention predisposes to stricture/bladder neck contracture.
- Disruption of pelvic floor with pelvic surgery may result in detrusor hyperreflexia.
- History of other medical conditions:
  - Neurologic disease—overactivity or bladder hypocontractility.
  - Diabetes—bladder hypertonia.
  - History of sexually transmitted infection(s)—urethral stricture disease.
  - History of pelvic radiation—urethral stricture disease or bladder hypertonicity.
- Elicit family history of genitourinary disease (BPH/LUTS, prostate cancer, prostatitis).
- Review medications as certain antihistamines, antimuscarinics, sympathomimetics, and bronchodilators may exacerbate LUTS.

PHYSICAL EXAM
- Abdominal exam to assess suprapubic region for bladder distension.
- Focused neurologic exam should be performed with particular attention to:
  - General mental status.
  - Ambulatory status.
  - Motor and sensory function of the lower extremities and perineum.
  - Anal sphincter tone.

In men:
- Inspection of the urethral meatus should be performed to rule out meatal stenosis.
- Digital rectal exam (DRE) should be performed to evaluate for:
  - Prostatic enlargement.
  - Nodularity or firmness suggestive of prostate cancer.
  - Regression or tenderness suggestive of prostatitis.
- Anorectal tone, abnormalities of which suggest neurologic disease.

In women:
- Speculum exam should be performed to evaluate for mass, prolapse, and urethral abnormalities.

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Urinalysis should be performed to evaluate for urinary tract infection or hematuria.
- Serum PSA should be considered as a diagnostic test (as opposed to a screening test).
- Serum creatinine is not recommended in the evaluation of routine LUTS associated with BPH.

IMAGING
- Imaging with CT or ultrasound (US) is not recommended as routine procedure.
- Upper tract imaging with either CT or US may be considered in the context of:
  - Acute symptom onset.
  - History of upper urinary tract infection or stone disease.
  - History of renal insufficiency.
  - Recent onset of nocturnal enuresis.
- Prostate imaging with transluminal US may provide information for treatment planning but is considered optional.

Diagnostic Procedures/Surgery
- Assessment of post-void residual urine with US imaging is recommended prior to intervention.
- Pressure flow urodynamic studies are not indicated in the evaluation of the uncomplicated patient with LUTS.
- Serum PSA should be considered as a diagnostic test (as opposed to a screening test).
- Assessment of urinary flow rate is optional that may predict response to invasive therapy.
- Immediate intervention for bladder function is optimal.
- Pressure flow urodynamic studies are not indicated in the evaluation of the uncomplicated patient with LUTS.
- May be useful in patients with mixed symptoms or neurologic disease to develop a therapeutic strategy.
- Cystoscopy is not recommended for the uncomplicated patient with LUTS.

Pathologic Findings
- Histopathology of BPH reveals proliferation of both stromal and glandular prostatic elements.

Risk Factors
- Increased risk of moderate-to-severe LUTS in men with a family history of BPH.
- The precise contribution of genetic and environmental factors to the development of LUTS remains largely unknown.
GENERAL MEASURES (1,2)

- Antimuscarinic agents can be used alone or in combination therapy (5) α–Side effects include decreased libido and sexual dysfunction.
- Finasteride or dutasteride α–Reductase inhibitors: reduce prostatic volume by 25%–30% in 1 year, reduce symptoms (I-PSS), reduce men’s likelihood of requiring intervention (5).
- Terazosin start 1 mg/d to max. 20 mg α–Side effects include syncope, orthostasis, retrograde ejaculation, asthenia, and nasal congestion.
- Tamsulosin start 0.4 mg to max. 0.8 mg α–Side effects include dizziness, orthostatic hypotension, headache, diarrhea.
- Silodosin 8 mg/d
- Doxazosin start 1 mg/d to max. 8 mg
- Alfuzosin 10 mg/d
- Proscar 5 mg
- Lotensin 2.5 mg

TREATMENT

**GENERAL MEASURES (1,2)**
- Treatment should be offered to men with moderate to severe symptoms (I-PSS ≥ 28) who are bothered enough to consider therapy.
- Men with demonstrable sequelae of BPH/BOO (renal failure secondary to obstruction, bladder calculi, etc.) should be counseled on benefits of treatment.
- Treatment is tailored to symptom type (obstructive, detrusor overactivity, etc.)
- Treatment should be offered to men with moderate to severe symptoms and prostatic enlargement.
- Combination therapy (α-adrenergic blocker + 5α-reductase inhibitor) should be considered in men with moderate to severe symptoms and prostatic enlargement.
- Saw palmetto is widely used to treat LUTS with little evidence of efficacy.

**MEDICATION**

**First Line**
- α-Adrenergic blockers: relax prostatic/bladder neck smooth muscle tone and improve symptoms (all appear to have equal effectiveness) –Adrenergic blocker + 5α-reductase inhibitor (5).

**Second Line**
N/A

SURGERY/OTHER PROCEDURES

- Urodynamics or direct visualized incision of urethral stricture (DVIU) should be considered for stricture/bladder neck contracture.
- Prostate repair should be considered for women with urinary symptoms and prolapse.
- Numerous surgical options exist for men with BPH/BOO (selective prostatectomy, transurethral resection of the prostate, transurethral microwave thermotherapy).

**FOLLOW-UP**

- Patient Monitoring: Monitoring with serial AUASS or IPSS to quantify symptom intensity and bother.
- Urinalysis, serum PSA, urinary flow rate, and postvoid residual as clinically indicated.

**COMPPLICATIONS**

- Complications of BPH/LUTS include:
  - Recurrent UTIs
  - Renal insufficiency
  - Bladder stone formation
  - Urinary retention
  - Secondary sterile pyelonephritis

**CLINICAL/SURGICAL PEARKS**

- Quantification of symptoms is paramount in the management of LUTS.
- Treatment should be offered to men with moderate to severe symptoms (AUASS ≥ 28).
- Treatment should be tailored to symptoms and prostate volume and may include behavioral intervention, medical management, or surgical intervention.

**REFERENCES**

**ADDITIONAL READING**

Lymphadenopathy, Inguinal

Michael E. Woods, MD
Ray S. Pruthi, MD, FACS

BASICS

DESCRIPTION
- Clinically evident inguinal lymphadenopathy can be secondary to infection, inflammation, or malignancy.
- Lymph nodes (LNs) are generally considered enlarged if > 1 cm.
- There is a > 1% annual incidence of unexplained peripheral (including inguinal) lymphadenopathy.
- 14% of all abnormal lymphadenopathy present in inguinal region

Epidemiology
Incidence
- Malignancy
  - Penile cancer (11A)
  - 0.4–0.64% of new cases in USA
  - Median age at diagnosis: 68 yr
  - 50% of enlarged LN secondary to cancer
- Lymphoma: ~80,000 cases/year in USA
- Infectious (STDS) (2A)
  - Approximately 15 million new Sexually Transmitted Infections (STIs)/year in USA
  - Chlamydia (Mannheimia haemolytica)–24 cases reported to the CDC in 2010
  - Herpes simplex: ~770,000 cases/year, 16% of 14–64 yr olds infected with HSV-2
  - Lymphogranuloma venereum (LGV)–relatively rare; rise in USA and UK associated with men who have sex with men and pierced with HIV
- Syphilis–In 2011, USA, men 82,100,000; women 1,100,000
- HIV–1.1 million people in USA infected
- Lymphogranuloma venereum (LGV)–relatively rare; increase in USA and UK associated with men who have sex with men and pierced with HIV
  - Syphilis–In 2011, USA, men 82,100,000; women 1,100,000
  - HIV–1.1 million people in USA infected
- Gonorrhea: 2nd commonest STI in USA

Risk Factors
- Penile Cancer
  - Circumcision (neonatal circumcision is protective)
  - Poor genital hygiene; phimosis
  - Number of sexual partners
  - Human papilloma virus (HPV) infection (type 16 and 18)
- Incidence of LN metastases related to grade, stage, and lymphovascular invasion
- 5% High-risk sexual practices (ie, nonuse of condom, multiple partners, men who have sex with men)

Pathophysiology
- Inguinal lymph nodes (ILNs) serve at the primary lymphatic drainage for the penis, scrotum, urethra, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower arm, and lower extremities.
- ILNs lie within the femoral triangle (inguinal ligament, sartorius, and adductor longus) and are separated into superficial and deep groups by the fascial lata of thigh.
- Penile squamous cell carcinoma (SCCs) cancer spreads by a relatively reliable pattern: From superficial pelvic LNs to deep pelvic LNs

Associated Conditions
- Bacterial
  - Phimosis
- Additional sexually transmitted infections (STIs)

General Prevention
- Population screening is protective against penile cancer
- Good genital hygiene
- STD education and safe sexual practices
- Sun protection against melanoma
- HPV vaccination may reduce risk (unproven)

Diagnosis

History
- Constitutional symptoms: Weight loss, night sweats
- Age: Penile cancer is more likely in older individuals, STI more common in younger patients
- Sexual history: Number and sex of partners, condom use
- Travel: International travel is a common source of STI

Physical Exam
- Genital exam
  - Lower extremities bilaterally for lesions
- Abdominal exam
  - Cachexia: Suggests systemic illness
  - Generalized lymphadenopathy (neck, axilla)
  - HIV, lymphoma

Imaging
- Formal pelvic exam in women
- Excisional biopsy of abnormal LN or primary lesion
- Inguinal US: Evaluate solid vs. cystic lesions; identify perineal tumor
- CT abdomen/pelvis: Extent of disease
- CT chest/CXR: Staging in settings of malignancy

Diagnostic Procedures/Surgery
- Biopsy of abnormal LN or primary lesion
- Bone marrow biopsy (lymphoma workup)

Differential Diagnosis
- Nonmalignant (lymphadenitis)
  - Malignancy: In a historic study of over 200 patients the order of malignancy in inguinal lymphadenopathy was: Cutaneous malignancy of the trunk, testes, ovaries, and penile cancer.
  - Infectious
    - Soft-tissue infection of the lower extremity
    - Staphylococcus aureus
- Drug-induced: Treatment of primary lesion
  - Nonspecific lymphadenitis
  - Inguinal lymphadenopathy is reasonable if there are no other clinical findings.

Diagnostic Tests & Interpretation
- CBC, basic metabolic panel, liver function testing (LFTs)
- Infectious/STD (2)
  - Gonorrhea
    - Nucleic acid amplification testing (ie, polymerase chain reaction [PCR] of vaginal samples, urine, or anal samples–90% sensitive
    - Cultures–72–95% sensitive, perform if drug resistance is suspected
  - Syphilis
    - Darkfield microscopy of primary chancre, screen with nontreponemal test (RPR, VDRL) confirm with positive test confirmed via western blot assays
  - Herpes simplex
    - Viral culture of active lesion (50% sensitive)
    - PCR of specimen from genital ulcer
    - Direct fluorescent antibody of specimen
    - Serology for HSV-1/2 (90% and 95% sensitivity and specificity, respectively)
    - HSV–Culture, Chlamydia trachomatis from ulcers or ulcers
    - PCR–95% sensitive (specific: non-FDA approved)
  - LGV: Serology for LGV antibody to LGV-1 antigens

Treatment
- Generalized lymphadenopathy should be referred for general evaluation
- A period of observation for localized lymphadenopathy is reasonable if there is no other clinical findings
- Penile cancer requires treatment of primary lesion (based on size and location) followed by inguinal lymphadenectomy if indicated
- Infectious etiologies need to be accurately diagnosed so appropriate treatment can be initiated (see below)

Medications: Cephalosporins, others

References
- Raj S. Pruthi, MD, FACS
- Michael E. Woods, MD

230
**SURGERY/OTHER PROCEDURES**

**Perineal cancer (CEA)**
- Management of primary lesion (local excision, partial penectomy, total penectomy)
- Non-palpable LNs
- Up to 50% of all enlarged LNs are benign in patients with newly diagnosed perineal cancer. Treated with 6 wk of antibiotics (currently controversial) prior to consideration of inguinal lymph node dissection (ILND) or undergone a fine needle aspiration of the node in question if the primary tumor is low-risk.
- Occult metastasis ~25% without frozen section
- T1G1—surveillance
- T1G2—surveillance if LND or dynamic sentinel node biopsy (DSNB)
- T2 or greater—LND or DSNB
- Papillary ULC: Low risk—consider fine-needle aspiration to confirm malignancy; Intermediate/high risk—LND
- Inguinal lymphadenectomy techniques
  - Dynamic sentinel node biopsy (DSNB)
  - Use of blue dye + y-emission (radio nuclide tracer)
  - False-negative 5%, expert required
  - Superficial LND
  - Removal of LN above fascia lata
  - If lymph positive on frozen section, then complete LND widened
  - Option for prophylactic LND
  - Modified LND
  - Appropriate for prophylactic LND
  - Decreased morbidity
  - Limited template (lateral border femoral artery, vastus lateralis fascia)
  - Includes deep nodes medial to femoral vein
  - Smaller incision, preserve saphenous vein
  - Avoids transection of sartorius muscle
  - Positive on frozen, then standard LND
  - Radiation-treated LND
  - Indicated for patient with metastatic disease to the LND
- Larger template including fascia lata and limits transection of femoral artery and dissection to apex of the femoral triangle
- Routine dissection of saphenous vein and sartorius muscle for complete superficial LND
- Infectious etiology
  - Fine-needle aspiration for culture
  - Incision and drainage of abscess
- Lymphoma
  - Fractional biopsy of LN (may consider other site if generalized lymphadenopathy is present)

**ADDITIONAL TREATMENT**

**Infection Therapy**

- Perineal Cancer: Radiation of bulky, unresectable inguinal lymphadenopathy

**Additional Therapies**
- Perineal cancer
  - Patients with fixed LNs or pelvic ULC should receive cisplatin-based chemotherapy followed by consolidative surgery when appropriate (3CE)
  - Paclitaxel, ifosfamide, cisplatin—50% complete response (CR) or partial response (PR) and ~70% undetectable planned surgery

**ONGOING CARE**

**PROGNOSIS**

- Perineal Cancer
  - Node negative: 46–100% 5-yr survival (mean ~75%)
  - Node positive: 0–86% 5-yr survival based on nodal burden (average ~60%)

**COMPLICATIONS**

- LND
  - Severe, lymphatic, wound infection, skin necrosis
  - 25–50% risk

**FOLLOW-UP**

- **Patient Monitoring**
  - **Perineal Cancer (CEA)**
    - 
    - N0: 1-2 then N1: 3-5
    - 0: 1-2 then N1: 3-5
    - N2: 1-2 then N3: 1-2 then N4=MO: 0–6
    - Infectious (CEA)
      - Chancroid—7–14 days after initiating treatment
      - LGV—nucleic acid amplification at 6–12 months
      - Gonorrhea—treatment if symptoms resolve

**Patient Resources**

**ADDITIONAL READING**

**CLINICAL/SURGICAL PEARLS**

- Differentiate inguinal adenopathy from more generalized LR involvement
- The viability of the skin flaps developed during an inguinal dissection are based on the anatomic vessels within the superficial fatty layer of Camper’s fascia which course lateral to medial along the skin lines. This is a key anatomic dissection plane of the lymphatic drainage of the penis lies beneath Camper’s fascia allowing this superficial fatty layer to remain attached to the skin flaps.
- Use a modified technique in a clinically negative groin to decrease morbidity. The key components: Shorter incision (~10 cm), preserve saphenous vein, minimize dissection lateral to the femoral artery, and avoid transection of the sartorius muscle.

**ADDITIONAL DRUGS**

- Azithromycin 2 g PO × wk
- Zinc (1 or doxycycline 100 mg or ciprofloxacin 500 mg PO × wk)
- Acyclovir 200 mg PO TID × wk
- Valacyclovir 1 g PO BID × wk
- Ceftriaxone 250 mg IM × 7–10 days or azithromycin 1 g PO × wk
- Vancomycin 1 g PO × wk
- Surveillance

**REFERENCES**

**LYMPHADENOPATHY, PELVIC AND RETROPERITONEAL**

Carrie L. Fitzgerald, DO, MPH  
James A. Brown, MD, FACS

**BASICS**

**DESCRIPTION**
- Enlarged nodal tissue in the pelvis and retroperitoneum
- Can be regional or generalized
- Definitions vary, but include solitary node ≥ 1–1.5 cm in short axis, any rounded node ≥ 8 mm or multiple nodes > 1 cm (1).
- Pelvic lymph nodes (LN) are generally considered abnormal if ≥ 1.3 cm.
- Often discovered incidentally or with imaging performed for tumor staging.
- Usually nonspecific, but potentially life threatening.

**EPIDEMIOLOGY**
- Lymphadenitis: seen with inflammatory/infectious conditions of the pelvis
- Immunosuppression (HIV, autoimmune)
- Prostate cancer
- Tumor-associated syndromes:
  - Possibly Apert syndrome
  - Li–Fraumeni syndrome
  - SBLA syndrome (Sarcoma, Breast, Lung, Adrenal carcinoma)
  - Gardner syndrome
- Tuberous sclerosis complex (TSC)
  - Birt–Hogg–Dube (BHD)
  - Hereditary leiomyomatosis and renal cell cancer
  - Hereditary papillary renal carcinoma (HPRC)
  - Hereditary pheochromocytoma (HPP)
- Tuberculosis scrofula (TSC)
- Adrenal cancer:
  - Gardner syndrome
  - Birt–Hogg–Dube syndrome (associated with hemihypertrophy)
  - Multiple endocrine neoplasia type 1
- SBLA syndrome (Sarcoma, Breast, Lung, Adrenal carcinoma)
  - Le–Rounds syndrome
- Urothelial cancer:
  - Hereditary nephropathy colon cancer (HNCC)
  - Hereditary retinoblastoma
  - Cowden syndrome
  - Possibly Apert syndrome
- Prostate cancer:
  - Hereditary breast and ovarian syndrome (BRCA2)
  - Patients with primary tumors of GI, GU, and GYN tracts and associated risk factors for these malignancies
  - Smoking, age, family history, HPV
- Immunosuppression (HIV, autoimmune)
- Lymphadenitis seen with inflammatory/infectious conditions of the pelvis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- CBC, ESR, exam of peripheral smear
- Creatinine (for imaging and to check renal function)

**Pathology**
- Urine cytology
- Urinalysis for hematuria
- Creatinine (for imaging and to check renal function)
- CBC, ESR, exam of peripheral smear
- PET: Evaluate fibrosis from metabolically active nodes, ie, postradiotherapy testicular cancer, seminoma (2), expanding role (3)
- Some studies show PET can define testicular relapse before CT
- SPECT: Advances in lymphoscintigraphy have advanced opportunity for TN injection in select GU malignancies (1)
- Bilateral lymphangiography largely replaced by CT and MRI

**Diagnostic Procedure/Surgery**
- Nodal tissue exam unless diagnosis is clear (ie, testicular or prostate tumor), then size or function and physiology becomes important (1).
- CT-guided biopsy best way to obtain nodal tissue.
  - Not always feasible (ie, proximity to major vessels), open/laparoscopic in select cases
  - CT-guided biopsy/SPECT imaging

**Pathologic Findings**
- Nodal, depends on cause (see below)

**DIFFERENTIAL DIAGNOSIS**
- Tumor:
  - Primary lymphatic: Lymphoma (non-Hodgkin, Hodgkin, others)
  - Secondary: Adrenal, renal, urothelial and nonurothelial bladder or upper tract cancer, prostate, urethral, penile, germ cell, ovarian, uterine, GI (carcinoid, lymphomas), colorectal, melanoma, Kaposi sarcoma
- Infections/inflammatory:
  - Granulomatous: TB, sarcoidosis, histoplasmosis, lymphogranuloma venereum, Castleman disease
  - Noninfectious: IL 1 receptor hyperactivity associated with HIV and human herpesvirus 8 (HHV-8)
  - Nongranulomatous: Viral, bacterial (Ab absence in local areas), sinus histiocytosis, retroperitoneal fibrosis
- Other:
  - Neoplastic, non-neoplastic, and cystic retroperitoneal masses (lymphocele, urinoma, hemorrhage) aneurysms
LYMPHADENOPATHY, PELVIC AND RETROPERITONEAL

TREATMENT

GENERAL MEASURES
- Wide variety, based on diagnosis of primary disease
- Image-guided needle biopsy, as a first-line investigation, is useful in the diagnosis of space-occupying lesions of the retroperitoneum
- Routine lymphadenectomy usually indicated for GU malignancy

MEDICATION
First Line
- Based on diagnosis of primary disease
Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Open or laparoscopic nodal sampling may be required in select cases
- Lymphadenectomy at time of organ-specific resection is indicated in many cases of GU, GYN, and GI malignancy

ADDITIONAL TREATMENT
- Underlying cause must be treated appropriately
- Benign reactive lymphadenopathy can be seen in the presence of malignancy and improves with appropriate treatment
- Radiation Therapy
  - For certain cases such as seminoma

ADDITIONAL THYERAPY
- In select cases, re-implanting for signs of growth or assessing therapeutic response, eg, hormonal therapy for prostate cancer, antibiotics for peritoneal cancer
- Notification of partner if HIV-positive [A]
- Complementary & Alternative Therapies
  - N/A

ONGOING CARE

PROGNOSIS
- Widely variable

COMPLICATIONS
- Severe lymphadenopathy can result in lower extremity edema, varicocele
- Potential surgical complications of retroperitoneal lymphadenectomy include vascular injury, lymphocele, chylous ascites, ejaculatory dysfunction, and GI complications (pancreatitis, bowel injury/infection)

FOLLOW-UP

Patient Monitoring
- Based on primary disease

Patient Resources
- N/A

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Groin/Inguinal Mass
- Lymphadenopathy, Inguinal
- Lymphadenopathy, Pelvic and Retroperitoneal
- Retroperitoneal Mass and Cysts

CODES

ICD9
- 202.80 Other malignant lymphomas, unspecified site, extranodal and solid organ sites
- 567.9 Unspecified peritonitis
- 785.6 Enlargement of lymph nodes

ICD10
- C85.90 Non-Hodgkin lymphoma, unspecified, unspecified site
- K65.9 Peritonitis, unspecified
- R33.0 Localised enlarged lymph nodes

CLINICAL/SURGICAL PEARLS

- General malignancies (testis, penile) have predictable lymphadenopathy pattern of spread.
- Pelvic organ malignancies may have skip lesions to the retroperitoneum.
- Lymphadenectomy may be curative for many urologic and hematologic malignancies.
- Urinary, bowel, and vascular obstruction possible with advanced lymphadenopathy.
- Inflammatory and infectious conditions may lead to reactive lymphadenopathy.
LYMPHOCELE, PELVIC
Rafael E. Yanes, MD
Fernando J. Bianco, Jr, MD

ASSOCIATED CONDITIONS
- Bladder cancer
- Gynecologic malignancy
- Penile cancer
- Prostate cancer
- Renal cancer
- Renal insufficiency with transplantation
- Retropertitoneal metastasis

GENERAL PREVENTION
- Multicystic lymphadenopathy with clips on proximal end of lymphatic vessels.
- Monopolar electrosurgery may not adequately seal lymph channels.
- Bipolar or harmonic devices have been shown to be effective (bipolar devices created seals that were 10-fold stronger than the harmonic devices).
- These vessel-sealing devices (VSDs) may reduce risk.
- Use of Floseal or other hemostatic products after lymphadenectomy may reduce the number of symptomatic lymphoceles.
- Some reports that the use of anticoagulants (eg, subcutaneous heparin) postop may increase risk.
**TREATMENT**

**GENERAL MEASURES**
- Treat DVT if present.
- Foley catheter if the patient has significant voiding dysfunction.
- Asymptomatic small lymphoceles should be monitored (< 100–150 mL volume). Many will resolve spontaneously.

**MEDICATION**

**First Line**
- Lymphocele management is primarily interventional with limited role for medications unless associated with infection or sclerosis (see below) (2).
- Systemic antibiotics (with percutaneous drainage) if lymphocele is infected.

**Second Line**
- N/A

**SURGERY/OTHER PROCEDURES**
- Treatment of symptomatic or large lymphoceles is immediate percutaneous drainage (3).
- Reported success rates with aspiration and drainage tube are approaching 80%, with a mean drainage duration ranging from a few days to several months.
- Increased risk of infection, especially in immunocompromised (transplant) patients.
- Sclerosis therapy can be used to treat extraperitoneal lymphoceles:
  - Sclerotherapy (povidone–iodine, 95% ethanol, tetracycline 0.5–2 g in 50 mL NS, bleomycin 1 U/mL, fibrin glue):
    - Cavity is aspirated, then filled gently with a sclerosing agent.
  - Multiseptated lymphoceles: Drainage, lack of access to all chambers.
  - When the ureter is in close contact with a wall of the lymphocele (periureteral fibrosis, ureteral obstruction)
  - Incomplete lymphoceles should not be treated by sclerosis.
- Transperitoneal laparoscopic marsupialization (4)
  - If unsuccessful sclerosis or not amenable to percutaneous drainage.
  - Three transperitoneal ports provide access for excision of the peritoneal window and optional omental wick placement to keep peritoneal window open.
  - Success: 77–100%
- Open marsupialization (internal drainage) into the peritoneum is the historic gold standard:
  - A window of peritoneum is created, allowing the lymph to be reabsorbed by the peritoneum.
  - Infected lymphoceles require percutaneous or open surgical drainage.
  - Ureteral obstruction:
    - Placing a portion of omentum in the window decreases recurrence maintaining patency.
    - Success: 75–100%

**ONGOING CARE**

**PROGNOSIS**
- Most smaller asymptomatic lymphoceles resolve spontaneously.
- >90% success with marsupialization.

**COMPLICATIONS**
- DVT/PE
- Lymphostasis of the lower extremity
- Infection
- Ureteral obstruction
- Bowel obstruction

**FOLLOW-UP**
- Repeat imaging: Ultrasound or CT in 2–4 mo after treatment to detect recurrence.

**REFERENCES**

**ADDITIONAL READING**
- See Also (Topic, Algorithm, Media)
  - Edema, External Genitalia
  - Lymphocele, Pelvic Images
  - Urinoma (Perinephric Pseudocyst)

**CODES**

**ICD9**
457.8 Other noninfectious disorders of lymphatic channels

**ICD10**
B89.8 Other noninfectious disorders of lymphatic vessels and nodes

**CLINICAL/SURGICAL PEARLS**
- Use of clips on identifiable lymphatic channels can minimize the occurrence of postoperative lymphoceles.
- A transperitoneal approach for lymphadenectomy is not protective against the formation of a lymphocele because loculation of lymphatic fluid can still occur.
- Symptomatic lymphoceles may require percutaneous or laparoscopic drainage.
**MEDULLARY CYSTIC KIDNEY DISEASE (MCKD)**
Scott G. Hubosky, MD

**BASICS**

**DESCRIPTION**
- Medullary cystic kidney disease (MCKD) is a rare congenital, cystic disease of the kidneys which results in progressive renal deterioration and to eventual end-stage renal disease (ESRD).
- Symptoms develop insidiously and diagnosis is not common until renal insufficiency is detected and initiates evaluation.

**EPIDEMIOLOGY**
- **Incidence**: Less than 1:100,000
- **Prevalence**: N/A

**RISK FACTORS**
- Positive family history
- Genetics
  - Mode of inheritance is autosomal dominant (AD)
    - Medullary cystic kidney disease-1 (MCKD1)
      - Mutation in MCKD1 gene localized to chromosome 1q21
    - MCKD2
      - Mutation in MCKD2 gene localized to chromosome 16p12

**PATHOPHYSIOLOGY**
- Unlike other renal cystic diseases such as autosomal dominant polycystic kidney disease (ADPKD), there is no clear correlation between genetic mutation and identifiable protein product responsible for the MCKD phenotype.

**ASSOCIATED CONDITIONS**
- Hyperuricemia and gouty arthritis are associated with MCKD2
- In contrast to juvenile nephronophthisis, MCKD does not have many extrarenal manifestations

**GENERAL PREVENTION**
- N/A

**DIAGNOSIS**

**HISTORY**
- Polyuria
  - Usually the 1st clinical manifestation
  - Occurs due to reduced urinary concentrating ability of the kidney
- Polydipsia
- Family history of ESRD, or renal cysts

**PHYSICAL EXAM**
- Hypertension may be noted with disease progression

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urinalysis
  - Proteinuria and hematuria are usually absent
- CBC
  - Anemia present in advanced cases due to lack of erythropoietin
- Serum electrolytes
  - Elevated creatinine
  - Hyperkalemia or metabolic acidosis in later stages due to renal insufficiency

**Imaging**
- Renal ultrasound
  - Kidneys may be atrophic depending on stage of disease
  - Cysts may be visible at the corticomedullary junction in later disease but are usually not detectable in early stages due to renal insufficiency
- CT scan
  - Can detect cysts at the corticomedullary junction better than ultrasound
  - Need for IV contrast is suboptimal in patients with ESRD

**Differential Diagnosis**
- Juvenile nephronophthisis
  - Clinically and anatomically similar to MCKD
  - Autosomal recessive inheritance
  - ESRD usually manifests as early as age 13 yr
  - Extrarenal manifestations are common
    - Retinal disorders (retinitis pigmentosa)
    - Hepatic fibrosis
    - Bardet-Biedl syndrome (obesity, retinitis pigmentosa, mental retardation, polydactyly)
- Polycystic kidney disease
  - Autosomal recessive polycystic kidney disease (infantile form)
  - Autosomal dominant polycystic kidney disease (adult form)
- Multicystic dysplastic kidney
- Benign multicystic (cystic nephroma)
- Medullary sponge kidney
MEDULLARY CYSTIC KIDNEY DISEASE (MCKD)

TREATMENT

GENERAL MEASURES
- Same as for any patient with renal insufficiency
  - Control hypertension if present
  - Monitor fluid/balanced electrolyte intake
  - Monitor serum electrolytes

MEDICATION
First Line
- None for primary treatment
- Antihypertensive regimen may be necessary

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Transplantation when ESRD develops
  - Allograft is not affected by MCKD after transplantation

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS
- MCKD1 patients manifest with ESRD at median age of 62 yr
- MCKD2 patients manifest with ESRD at median age of 32 yr

COMPLICATIONS
Similar to any patient with renal insufficiency or ESRD

FOLLOW-UP
Patient Monitoring
Close nephrology follow-up is essential

Patient Resources
- National Kidney Foundation
  - www.kidney.org/patients

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Nephronophthisis (Juvenile, Infantile, and Adolescent)
- Renal Cysts (Intrarenal, Peripelvic, and Parapelvic)
- Renal Mass

CODES
ICD9
- 585.6 End stage renal disease
- 753.16 Medullary cystic kidney
- 788.42 Polyuria

ICD10
- N18.6 End stage renal disease
- Q61.5 Medullary cystic kidney
- R35.8 Other polyuria

CLINICAL/SURGICAL PEARLS
- MCKD has an insidious disease onset.
- Symptoms generally not present until patient has renal insufficiency documented on serum testing.
- Polyuria is commonly the 1st clinical manifestation.
**BASICS**

**DESCRIPTION**

Medullary sponge kidney (MSK) consists of developmental abnormalities of the kidneys with ectatic or dilated terminal collecting ducts and associated medullary cysts.

**EPIDEMIOLOGY**

Incidence

N/A

**Prevalence**

• Estimated at 1 in 5,000–20,000 in the general population

• Occurs more frequently in stone formers ranging from 5 to 20%

• Identification and therefore recognized incidence of MSK may be decreasing since it depends on radiographic contrast studies to detect the dilated collecting ducts.

**RISK FACTORS**

N/A

**GENETICS**

Many cases may be sporadic:

• Increasing evidence suggests inheritability of the disorder, possibly of an autosomal dominance based on familial studies

• Mutations in glial cell–derived neurotropic factor (GDNF) account for roughly 12% of MSK cases

**PATHOPHYSIOLOGY**

• Dilated collecting ducts and medullary pyramidal cysts which may actually represent ectatic ducts

• Dilated ducts may be filled with calcium apatite crystal

• Distal renal tubular acidosis (DRTA) (33–40%)

• Hypercalcitria (9–100%)

• Hypo-citraturia (19–83%)

• Hypocalciuria (9–100%)

• Distal renal tubular acidosis (DRTA) (33–40%)

• Calcium phosphate predominate in 63–67%

• Calcium oxalate monohydrate 33% (pure) to 63% (mixed)

• Calcium oxalate dihydrate 10–40% (mixed)

• May show hypercalciuria (9–100%)

• 24-hr urine collections

• Serum electrolytes usually are normal except with episodes of pain

**ASSOCIATED CONDITIONS**

• Renal calculus

• Urinary tract infections (UTIs)

• Hypo-citraturia and hypercalcitria (as noted above)

• Reduced bone density (2)[B]

**GENERAL PREVENTION**

• This developmental condition cannot be prevented

• Secondary complications (infections, urolithiasis) can be prevented by appropriate measures

**DIAGNOSIS**

**HISTORY**

• Many patients are asymptomatic and are diagnosed incidentally on contrast studies

• Pain associated with renal/ureteral calculi

• Pain without associated obstructing calculi

• Hematuria, microscopic or gross

**PHYSICAL EXAM**

• May be normal without associated findings

• May have flank tenderness, especially among those with episodes of pain

**DIAGNOSTIC TESTS & INTERPRETATION**

**HISTORY**

• Many patients are asymptomatic and are diagnosed incidentally on contrast studies

• Pain associated with renal/ureteral calculi

• Pain without associated obstructing calculi

• Hematuria, microscopic or gross

• 24-hr urine collections

• Serum electrolytes usually are normal except with episodes of pain

**IMAGING**

• CT urogram (CTU) may be most useful imaging study

• After the injection of contrast for CTU, a blush of the involved papillae may be seen

**LAB**

• Urinalysis

• Microhematuria or pyuria

• 24 hr urine collections

• May show hypercalciuria (9–100%)

• May be normal without associated findings

• May have flank tenderness, especially among those with episodes of pain

**DIFFERENTIAL DIAGNOSIS**

• Dent disease

• Other rare abnormalities of calcium phosphate metabolism

• Primary hyperparathyroidism

• RTA

**TREATMENT**

• Noncontrast CT (NCCT) has largely replaced contrast studies (IVU, EXU) in the diagnosis urinary calculus disease

• May demonstrate multiple calcifications and possibly localize them to the renal pyramids (IVU)

• CT urogram (CTU) may be most useful imaging study

• After the injection of contrast for CTU, a blush of the involved papillae may be seen

**DIAGNOSTIC PROCEDURES/SURGERY**

• Endoscopy, specifically ureteroscopy differentiates intraluminal from intraparenchymal calcifications (IVU or EXU)

• 24-hr urine studies to identify metabolic abnormalities

**PATHOLOGIC FINDINGS**

• Typical sponge appearance of the medulla results from the dilated intrapapillary collecting ducts and small medullary cysts

• Calcifications may be found in the dilated collecting ducts

• May be used to detect obstruction in the symptomatic patient

**GENERAL MEASURES**

• Majority of asymptomatic patients can be observed

• General stone clinic measures including high fluid intake should be maintained

• Alkalization with potassium citrate appears to be of value

• Other abnormalities such as hypercalciuria which do not resolve should be treated specifically

• Treat UTIs as necessary
MEDULLARY SPONGE KIDNEY (MSK)

**MEDICATION**
- Potassium citrate is employed in patients with hypocitraturia (5).
- Thiazide diuretics are used in patients with stones and nonresponsive hypocitraturia.
- Specific antibiotics are indicated for the treatment of UTIs.
  - Suppressive antibiotics may be necessary in patients with persistent or multiply recurrent UTIs.

**SURGERY/OTHER PROCEDURES**
- Shock wave lithotripsy has been utilized for treatment of collecting duct stones that can be distinguished from nephrocalcinosis as well as symptomatic intratubular calculi.
- Endoscopy with ureteroscopy or occasionally percutaneous nephrostolithotomy can treat collecting system stones and unroof mucosa to remove obvious and accessible collecting duct stones.
- SWL and endoscopy have been advocated to reduce the frequency of symptomatic episodes but is unproven.

**ADDITIONAL TREATMENT**
- Radiation Therapy: N/A
- Additional Therapies: N/A
- Complementary & Alternative Therapies: N/A

**ONGOING CARE**

**PROGNOSIS**
- Urinary calculi are the most common risk but can be followed and also may be controlled with medical treatment.
- Recurrent UTIs can usually be treated.
- Development of renal failure is very uncommon.

**COMPLICATIONS**
- Stone formation and subsequent obstruction
- Recurrent/chronic flank pain
- UTI

**FOLLOW-UP**
- Imaging at every 6–12 mo in stone formers to evaluate for change in existing stones or appearance of new ones.
- In some patients, renal ultrasound (RUS) can be used to monitor stones and avoid sedation.
- 24-hr urine collections are used to monitor stone risk factors during treatment for urinary abnormalities.
- Serum studies are used to monitor changes related to medication.

**REFERENCES**

**ADDITIONAL READING**

**FOLLOW-UP**

**Patient Monitoring**
- Imaging at every 6–12 mo in stone formers to evaluate for change in existing stones or appearance of new ones.
- In some patients, renal ultrasound (RUS) can be used to monitor stones and avoid sedation.
- 24-hr urine collections are used to monitor stone risk factors during treatment for urinary abnormalities.
- Serum studies are used to monitor changes related to medication.

**Patient Resources**
- National Kidney and Urologic Diseases Information Clearinghouse (NCCD) [website]. Available at: http://kidney.niddk.nih.gov/kudiseases/pubs/medullaryspongekidney/

**CODES**
- ICD9
  - 588.89 Other specified disorders resulting from impaired renal function
  - 592.0 Calculus of kidney
- ICD10
  - N20.0 Calculus of kidney
  - N25.89 Oth disorders resulting from impaired renal tubular function
  - Q61.5 Medullary cystic kidney

**ICAL/SURGICAL PEARLS**
- Be suspicious of MSK in patients with multiple papillary calculi.
- Use contrast study for diagnosis.
- Search for metabolic defects.
- Treat metabolic factors in stone formers.
- Consider treatment of renal stones in patients with recurrent symptomatic stones.
- Significant benefit in endoscopic inspection and treatment.
MEGAURETER, CONGENITAL
Ahmad H. Bani-Hani, MD, FAAP, FACS

**BASICS**

**DESCRIPTION**
- Megaureters is a ureter that is dilated out of proportion to the rest of the urinary tract.
- Most consider ureters measuring ≥7 mm in diameter by ultrasound a megaureter.
- Four types of megaureter are described:
  - Refluxing megaureter
  - Obstructed megaureter
  - Restricting and obstructed megaureter
  - Nonrefluxing, nonobstructed megaureter
- Each of the above groups further categorized as either primary (defect lies in the ureter itself) or secondary (another disorder leading to megaureter such as urethral obstruction)
- Primary megaureter represents the 2nd most common cause of hydronephrosis in the newborn, with urethral outlet obstruction the most common cause.

**EPIDEMIOLOGY**

**Incidence**
- Varies depending on etiology
  - Vesicoureteral reflux (VUR): 0.4–1.8% in children
  - Primary obstructive megaureter (POM): 1 per 10,000 population
- VUR is more common in females
- POM is more common in males with predilection for the left kidney
- Bilateral involvement in up to 40%

**Prevalence**
- N/A

**RISK FACTORS**
- Pediatric urinary valves
- Neurogenic bladder
- Diabetes insipidus

**Genetics**
- No specific genetic factors can be identified in the majority of patients with megaureters
- VUR can be familial

**PATHOPHYSIOLOGY**

- Refluxing megaureter:
  - Caused by congenital abnormality of the intravesical ureter and secondary to abnormal insertion of the ureter into the bladder or the intravesical portion of the ureter is not long enough to enable closure of the ureter during bladder filling
- POM:
  - Exact etiology is unclear; however, the most common finding is a distal adynamic intravesical segment that affects the free eflux of urine resulting in a functional obstruction

- Refluxing, obstructed megaureter:
  - This paradox of pathology was 1st reported by Weiss and Lytton. The muscle cells in the intravesical and extravesical segments of the distal ureter are so lacking that they become incapable of adequate transmission of urine. On VCUG, delayed emptying of the refluxing contrast brokers cut-off distally is highly suggestive of the diagnosis

- Nonrefluxing, nonobstructed megaureter
  - Ureter are so lacking that they become incapable of adequate transmission of urine. On VCUG, delayed emptying of the refluxing contrast brokers cut-off distally is highly suggestive of the diagnosis

- Nonrefluxing, nonobstructed megaureter
  - Secondary to urethral valves if present
  - Can be combined with transurethral resection of urethral valves if present

**ASSOCIATED CONDITIONS**
- Prune belly syndrome

**DIAGNOSIS**

**HISTORY**

- Most megaureters are diagnosed currently prenatally with ultrasound or amniocentesis.
- For late diagnosis, patients may present with abdominal pain, UTIs, or kidney stones.

**PHYSICAL EXAM**

- Abdominal mass
- Abdominal pain and costovertebral angle tenderness with pyelonephritis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urine analysis and culture if UTI is suspected
- Serum electrolytes, BUN, and creatinine
- C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) for pyelonephritis

**Imaging**
- Normally best to perform ultrasound imaging several days after birth to allow relative newborn dephosphatation to equilibrate
- Renal and bladder ultrasound:
  - Establishes the diagnosis of megaureter, assesses renal parenchyma and may provide clues on possible etiology eg thickened bladder wall secondary to urethral valves
- Voiding cystourethrogram:
  - Will evaluate for the presence of VUR and urethral abnormalities such as anterior or posterior urethral valves
- Diuretic renal scan:
  - Will evaluate for the presence of VUR and urethral abnormalities such as anterior or posterior urethral valves
- Retrocaval/retroiliac ureter:
  - Will provide valuable information if diuretic renal scan is equivocal
- Endoscopy: Invasive test as it requires anesthesia.
  - Can be combined with transurethral resection of urethral valves if present

**Pathologic Findings**
- VUR with obstruction
- Electron microscopy, muscle population and collagen types I and III deposition

**DIFFERENTIAL DIAGNOSIS**
- Bowel segment misinterpreted as dilated ureter
- Horseshoe kidney
- Prune belly syndrome
- Renal and ureteral duplication
- Ureterovesical junction obstruction
- VUR
MEGAURETER, CONGENITAL

GENERAL MEASURES
-Serial renal and bladder ultrasounds to monitor progress/resolution of megaureter is important.
-Workup of megaureter to assess the presence or absence of reflux and/or obstruction will guide further treatment options.

Prenatally discovered megaureter
- Unilateral obstructed megaureter has a good prognosis.
- These patients can be followed expectantly in the prenatal period, without further intervention or early delivery.

Bilaterally obstructed megaureter findings require close monitoring for the development of oligohydramnios.

MEDICATION
First Line
- Treat active UTI with culture appropriate antibiotics.
- Consider prophylactic antibiotics in refluxing and obstructed megaureter variants (eg, Amoxicillin).

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Refluxing megaureters:
  - Antibiotic prophylaxis and monitor progress with renal ultrasound (RUS) and VCUG.
  - Ureteral reimplant in cases of breakthrough UTIs, renal scarring, or noncompliance with medications.

Primary obstructed megaureter
- Excision of the distal adynamic ureteral segment and ureteral reimplant. Ureteral tapering maybe required.

Refusing, obstructed megaureter:
- Excision of the distal ureteral segment and ureteral reimplant. Often requires ureteral tapering.

Nonrefluxing, nonobstructed megaureter:
- Observation with serial ultrasound is all that is needed.

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

ONOGH CARE
PROGNOSIS
- Depends on the baseline renal function.
- Surgical correction of obstructing megaureters carries a high success rate.
- Most nonobstructive, nonrefluxing megaureters will resolve with time.
- Outcomes can be poor with concomitant renal anomalies such as renal hypoplasia and dysplasia.

COMPLICATIONS
- UTIs
- Ureteral obstruction, mainly technical issues to details during ureteral reimplant that will cause either:
  - Ureteral kinking at the bladder insertion site.
  - Compromised blood supply to the distal ureter associated with excisional ureteral tapering.
- Nephrolithiasis

FOLLOW-UP
Patient Monitoring
- Serial RUS (3)[A]
- Serial serum chemistry to monitor renal function.

Patient Resources
- Urology Care Foundation http://www.urologyhealth.org/urology/index.cfm?article=3

- Hydronephrosis/Hydroureteronephrosis, Dilated Ureter/Renal Pelvis, Prenatal
- Megaureter, Congenital Image
- Pediatric Urinary Tract
- Prune Belly Syndrome
- Vesicoureteral Reflux

ICD9
753.22 Congenital obstruction of ureterovesical junction

ICD10
Q62.2 Congenital megaureter

Wee spread use of prenatal ultrasound helps identify patients with megaureters at an early stage, commonly prenatally.
- It is important to classify megaureters based on their refluxing and/or obstructing status with the aid of VCUG and diuresis renal scan.
- Long-term follow-up in patients with megaureter is important for best outcome.
MESOBlastic NEPHROMA, CONGENITAL (BOLANDE DISEASE)

Lauren N. Hendrix, MD
Stephen E. Strup, MD, FACS

**BASICS**

**DESCRIPTION**
- Congenital mesoblastic nephroma (CMN) is a renal tumor arising from nephrogenic mesenchyme
- Usually a solid lesion, but cystic varieties have been reported
- Majority are benign with a favorable prognosis
- First reported in 1967, referred to in older literature as Bolande’s tumor or Bolande disease

**Epidemiology**
- Incidence
  - Most common real tumor in children <6 mos of age, usually diagnosed prior to 3 mos
  - Accounts for 3–10% of all pediatric renal neoplasms
- Prevalence
  - N/A

**Risk Factors**
- Genetics
  - ETV6-NTRK3 gene fusion
    - Results from translocation t (12;15) (p13;q25)
    - Found only in the cellular variant
    - Also found in congenital fibrosarcoma

**Pathophysiology**
- Tumor classification
  - Stage I: Tumor limited to kidney without involvement of capsule or hilar vessels
  - Stage II: Tumor extends beyond capsule with invasion into perinephric fat or blood vessels, but margins of resection are negative
  - Stage III: Tumor not completely resectable, tumor spillage occurs at time of resection, or tumor was biopsied preoperatively
  - Stage IV: Hemorrhagic metastases or lymphatic spread outside of abdomen
  - Stage V: Bilateral tumors

**Associated Conditions**
- Polyhydramnios
- Hydrops fetalis

**DIAGNOSIS**

**History**
- History of prenatal ultrasound finding of unilateral renal mass
- History of polyhydramnios
- Neonate with abdominal mass
- Hematuria, jaundice, hypertension, anemia, hypercalcemia

**Physical Exam**
- Palpable abdominal mass
- Hematuria
- Jaundice

**Diagnostic Tests & Interpretation**
- Lab
  - Complete blood count
  - Basic metabolic panel
    - Serum creatinine
    - Serum calcium
  - Urinalysis
- Imaging
  - Abdominal ultrasound
    - Preferred modality
    - “Ring pattern”
    - Hypoechoic mass with hyperechoic rim signifying vessels at the tumor periphery
    - Seen only in the classic variant
  - CT
    - Homogeneous mass
    - May have peripheral enhancement or focal enhancement at sites of hemorrhage or necrosis
  - MRI
    - Signal similar to normal parenchyma with exception of areas of hemorrhage

**Diagnostic Procedures/Surgery**
- Biopsy
  - The role of biopsy in pediatric renal tumors is controversial as nephrectomy is the mainstay of treatment and preoperative biopsy upstages to stage III

**Pathologic Findings**
- Three histologic subtypes
  - Classic
    - 1/3 of cases
    - Similar macro- and microscopically to leiomyoma
    - Entrapped nephrons and blood vessels seen at the tumor periphery
    - Not associated with metastasis
  - Cellular
    - 2/3 of cases
    - More aggressive than classic with high mitotic index and atypical growth pattern
    - Associated with local invasion/recurrence and metastasis
    - Mixed (5)

**Differential Diagnosis**
- Solid renal mass
  - Wilms tumor
  - Rhabdoid tumor
  - Metanephric adenofibroma
  - Renal cell carcinoma
  - Angiomyolipoma
  - Clear cell sarcoma
  - Multilocular cystic nephroma
  - Autosomal recessive polycystic kidney disease
  - Cross fused ectopia
  - Renal vein thrombosis
  - Solitary kidney with compensatory hypertrophy
  - Beckwith-Wiedemann syndrome
  - Adrenal mass
  - Renal parenchymal mass (3)
MESOBLASTIC NEPHROMA, CONGENITAL (BOLANDE DISEASE)

**GENERAL MEASURES**
- Management of associated features
  - Hypertension
  - Hypercalcemia
  - Jaundice
  - Anemia
- Chemotherapy reserved for patients >3 mo with cellular variant, tumor spillage at resection, microvascular invasion, metastatic disease, and inoperable tumors

**MEDICATION**
- **First Line**
  - Vincristine, cyclophosphamide, and doxorubicin (VCD)
- **Second Line**
  - Isophosphamide, carboplatin, etoposide (ICE) – Has considerable nephrotoxicity (3)

**SURGERY/OTHER PROCEDURES**
- Radical nephrectomy – Gold standard – Allows for appropriate staging – Decreased risk of local recurrence
- Partial nephrectomy – Has been reported with success in Wilms tumors but not CMN

**ADDITIONAL TREATMENT**
- Radiation Therapy – No defined role
- Complementary & Alternative Therapies – N/A

**ONGOING CARE**

**PROGNOSIS**
- Radical nephrectomy generally curative
- Classic variant favorable
- Metastases and local recurrence possible with cellular type, but rare
- Risk factors for recurrence: Cellular variant, older patient age, tumor spillage during resection, and positive surgical margins (3)

**COMPLICATIONS**
- Prenatally
  - Polyhydramnios
  - Hydrops fetalis
  - Intrauterine fetal demise
- After birth
  - Hypertension
  - Hemodynamic instability
  - Respiratory distress

**FOLLOW-UP**
- Patient Monitoring
  - Regular abdominal ultrasound for 1 yr in classic variant and longer in cellular variant
  - Patient Resources
    - www.cancer.gov/cancertopics/pdq/treatment/wilms/Patient

**REFERENCES**

**ADDITIONAL READING**

**CLINICAL/SURGICAL PEARLS**
- Most common solid renal tumor <6 mo of age.
- Radical nephrectomy is generally curative.

**CODES**
- **ICD9**
  - 236.91 Neoplasm of uncertain behavior of kidney and ureter
- **ICD10**
  - D41.00 Neoplasm of uncertain behavior of unspecified kidney
  - D41.01 Neoplasm of uncertain behavior of right kidney
  - D41.02 Neoplasm of uncertain behavior of left kidney
MICROPENIS (MICROPHALLUS)
Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

ASSOCIATED CONDITIONS
- Hypogonadal hypopituitarism
  - Most common cause of micropenis
  - Kallmann syndrome. Anosmia, defect in GnRH secretion, autosomal dominant
  - Prader–Willi syndrome. Short stature, hyperthermia, hypogonadism, behavior problems, hypothyroidism
  - Laurence–Moon–Biedl syndrome
  - Rud's syndrome
- Primary testicular failure: Gonadal dysgenesis
- Anorchia
- Klinefelter syndrome
- Luteinizing hormone (LH) receptor defects
- Defects in T steroidogenesis
- Noonan syndrome
- Rud's syndrome
- Laurence–Moon–Biedl syndrome
- Trisomy 18, 19, 18, and 21
- Defects in T action
- PAIS
- Sw-reductase deficiency
- Idiopathic form:
  - Normal hypothalamic–pituitary–testicular axis
  - Hypothesized to be due to delayed onset of fetal gonadotropin stimulation

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Pale suggestive of midline oral defect, mental retardation
  - Microcephaly, hypertelorism, low-set ears, small mouth, high-arched palate
  - Weight and body habitus. Prader–Willi syndrome, growth hormone abnormality
- Skin: Nails, ichthyosis
- Haring: Deafness
- Smell: Anosmia suggests Kallmann syndrome
- Family history: Germline mutations, hypoplasia, cryptorchidism, infertility, major congenital abnormalities
- Newborn:
  - Measure serum T and DHT levels on days 0 and 4.
  - If at day 4 > 500 ng/dL, response is normal. If no response, suggest primary testicular failure
  - Low prolactin suggests pituitary defect
  - Increased FSH ratio with hCG stimulation test or postpubertal suggests T-reductase deficiency
  - AR-gene mutation only found in 20% of PAIS

LAB
- Genetic testing if history consistent with known syndromes such as Prader–Willi or Kallmann
- Differentiate between hypogonadal and primary testicular failure
- Pituitary: Assesses ACTH, GH, TSH, LH, FSH.
- Low levels suggest hypogonadal hypopituitarism
- High prolactin suggests hypothalamic defect vs. low prolactin suggests pituitary defect
- Elevated levels of LH, FSH, and T are normal during 1st 6 mos of life. Low T during this time suggests testicular failure. Confirm with hCG stimulation test. LH, FSH should elevate but T will remain low in testicular failure
- hCG stimulation test. Assesses testicle for T biosynthesis. 1,000 U of hCG IV or IM thrice daily, measure serum T and DHT levels on days 0 and 4. If T at day 4 > 500 ng/dL, response is normal. If no response, suggest primary testicular failure
- From 6 mos to puberty, levels of LH, FSH, and T are low. LH, FSH elevate with hCG stimulation test but serum T low in testicular failure
- For patients who have undergone or started puberty, LH and FSH are normally elevated as may be serum T. LH, FSH, and T are usually low in micropenis. Do hCG stimulation test and look for response; assess pubertal changes to be sure it is not constitutional pubertal delay
- Anti-Müllerian hormone is produced by functional Sertoli cells and can be used to detect functional testis tissue
- Identifying defects in T action
  - LH, FSH, T, normal, or elevated with PAIS
  - PAIS diagnosis often given after excluding other diagnoses
  - Family history: Germline mutations, cryptorchidism, infertility, major congenital anomalies
- Newborn:
  - Measure serum T and DHT levels on days 0 and 4.
  - If at day 4 > 500 ng/dL, response is normal. If no response, suggest primary testicular failure
  - Low prolactin suggests pituitary defect
  - Increased FSH ratio with hCG stimulation test or postpubertal suggests T-reductase deficiency
  - AR-gene mutation only found in 20% of PAIS

IMAGING
- MRI of head: Assess hypothalamus, pituitary, brain, cerebellar anomalies, optic chiasm, 4th ventricle, corpus callosum
- Renal imaging: Assess kidneys and bladder, VCUG and MAMO renal scan if US suggest renal or bladder anomaly or ectopia

Diagnostic Procedures/Surgery
- Suspension to assess palpable undescended testicles, look for mullerian duct structures, biopsy any dysgenetic tissue
- Genitoectomy indicated if dysgenetic gonads, ovotestis, mullerian duct structures are found or if androgen insensitivity is suspected

PATHOPHYSIOLOGY
- Normal penile growth and development is both androgen dependent and independent
- 1st trimester: Maternal hCG stimulates testicle Leydig cells to produce testosterone (T). T is converted to dihydrotestosterone (DHT) by 5α-reductase in genital tubercle. Penis and urethra are completely formed by end of 1st trimester by influence of DHT.
- 2nd trimester: Fetal androgens and pituitary drive T production by fetal testes which causes penile growth
- Micropenis believed to be due to inadequate fetal T production or action after the 1st trimester (3).

EPIDEMIOLOGY
- Prevalence: ∼1.5/10,000
- Incidence: None

RISK FACTORS
- Maternal exposure to antiandrogen medications during pregnancy
- Advanced maternal age
- Fetal androgen exposure during molar pregnancy can lead to Down, Klinefelter syndromes, and polygony X syndromes

GENETICS
- X-linked recessive, autosomal recessive, autosomal dominant have all been identified
- Idiopathic spontaneous mutations noted
- Specific known genetic conditions:
  - Kallmann syndrome
  - Prader–Willi syndrome
  - Laurence–Moon–Biedl syndrome
  - Polygony X (Klinefelter)
  - Translocation, deletion, trisomy of chromosome 8, 18, 19, and 21
- Partial androgen insensitivity syndrome (PAIS)
- 5α-reductase deficiency
- Noonan syndrome
- Rud's syndrome

DIAGNOSIS

BASICS
- A micropenis refers to a stretched newborn penis that is <2.5 standard deviations below the normal mean in length (1)
- Full-term newborn micropenis would be <1.9 cm in length (1)
- Typical normal mean stretched penile length in a newborn is 5.5 cm
- The penis is normally formed but small, ie, no hypospadia (2)
- Scrotum usually normal but can be smaller
- Testicles usually descended but may not function normally
- A micropenis is generally not considered to be associated with ambiguous genitalia since the penis is normal and the testes are usually descended
- A micropenis is a finding with many causes

DESCRIPTION
- Micropenis believed to be due to inadequate fetal T production or action after the 1st trimester (3).
- Full-term newborn micropenis would be <1.9 cm in length (1)
- Typical normal mean stretched penile length in a newborn is 5.5 cm
- The penis is normally formed but small, ie, no hypospadia (2)
- Scrotum usually normal but can be smaller
- Testicles usually descended but may not function normally
- A micropenis is generally not considered to be associated with ambiguous genitalia since the penis is normal and the testes are usually descended
- A micropenis is a finding with many causes
Pathologic Findings
- Newborn penis is proportional but <1.5 cm
- Kallmann syndrome: Anosmia, GnRH deficiency
- 10% KALL: gene defect on 8p22.3, 10% KAL2 on 8p12, 7% autosomal dominant with no identified gene defect
- Pedlar-Wills syndrome: Short stature, hypothyroidism, mental retardation, diabetes, hypertension, behavioral problems; isolated expression of gene SNRPN or neulin on 15q of paternal origin
- Laurence-Moon-Biedl syndrome: Obesity, retinopathy, pigmentary retinopathy, polycystic kidney disease

DIFFERENTIAL DIAGNOSIS
- Concluded penis: Large suprapubic fat pad
- Webbed penis: Prominent penoscrotal web

Postinfection stenosis: Residual foreskin scarred above glans tip

Hypospadias with and without chordee

Chordee

Disorders of sexual differentiation:
- Female DSD: Congenital adrenal hyperplasia, genitoplasty not palpable in labia/crurum
- Male DSD
- Hypothalamic-pituitary axis dysfunction (50% of cases): Syndromes: Kallmann, Pedlar-Wills, Laurence-Moon-Biedl, Rud's
- Isolated hormone deficiency: Gigyn deficiency without Kallmann syndrome
- LH deficiency
- GH deficiency or growth hormone receptor defect (Laron dwarfism)

Primary testicular failure:
- Hypogonadotropic hypogonadism (25% of cases): Testicular dysgenesis, Klinefelter syndrome
- Laurence-Moon-Biedl syndrome
- Polygyn X syndrome
- Anorchia: Intradermal testicular tissue

Swiss-case deficiency: None

MAIS (Partial androgen insensitivity syndrome)

CHS abnormalities:
- Anorchia, congenital phallic aplasia, agenesis of corpus callosum, malformation of fourth ventricle

Chromosome defects:
- Polysomy X syndromes
- Translocation, deletion, and trisomy of chromosomes 8, 13, 18, and 21
- Rare syndromes: Rud, Robinow, Mortendsohn, Fanconi anemia, Smith-Lemli-Opitz syndromes

Hypospadias: Normal hypothalamic pituitary axis: Virilize normally at puberty

TREATMENT
GENERAL MEASURES
- Generally coordinated with an endocrinologist
- Correct any metabolic disturbances
- Specific treatment based on cause

Adrenal insufficiency: Treat with hydrocortisone supplementation and IV saline to correct hypovolemia

MEDICATION
First Line
- Testosterone therapy: Diagnostic and therapeutic
  - 25-50 mg testosterone enanthate IM Q monthly × 3 mo in infancy or prepuberty

Long-term cortisol replacement, growth hormone, and thyroid hormone if panhypopituitarism present

For gonadal deficiency: Induce puberty later in life with T injection or transdermal patch

For central deficiency: Administer HCG injection or GnRH therapy

Second Line
- None

SURGERY/OTHER PROCEDURES
- Manage cryptorchidism with orchiopexy or orchiectomy (if dysgenetic) as needed
- Manage micropenis: Effect of testosterone treatment on adult penis size—why sex reversal is not indicated.

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Androgen insensitivity syndrome (AIS), Androgen Resistance Syndrome, Complete (CAIS) and Partial (PAIS)
- Disorders of sexual differentiation (DSD)
- Micropenis (Microphallus)

ONGOING CARE
PROGNOSIS
- Overall good, but long-term effects depend on underlying cause
- Most will have stable male gender identity
- Generally good response to 3-mo course of T IM with 100% increases in length seen (3)
- Final adult penis size with treatment usually ≤normal, but within 2.5 standard deviations (3)

COMPLICATIONS
- Relate to endocrine abnormalities if present
- Side effects of testosterone:
  - Premature closure of epiphyseal plates; limits long bone growth
  - Behavioral changes: More aggressiveness
  - Early stimulation of penis growth does not affect ultimate penis length
- Psychosocial issues:
  - Most patients have a stable male gender identity but some dissatisfied with penis length
- Gender reassessment: Generally not done any more for micropenis and is of only historical interest

M

TREATMENT
GENERAL MEASURES
- Generally coordinated with an endocrinologist
- Correct any metabolic disturbances
- Specific treatment based on cause

Adrenal insufficiency: Treat with hydrocortisone supplementation and IV saline to correct hypovolemia

MEDICATION
First Line

  - Early stimulation of penis growth does not affect ultimate penis length
- Psychosocial issues:
  - Most patients have a stable male gender identity but some dissatisfied with penis length

FOLLOW-UP
- Patient Monitoring
  - Psychological support and psychiatric therapy as needed
  - Measure concerns about penis size, function, gender, potency
  - Address behavioral and psychosocial problems

- Hormone biochemical monitoring:
  - Follow pubertal and gonadal hormone therapy

- Assess growth, vital signs, electrolytes, serum glucose, renal, ACTH, TSH, GH, and T.

- Physical monitoring: Serial penile measurements

PATIENT RESOURCES
- None

CODES
ICD9
752.64 Micropenis
ICD10
Q73.6 Hypoplasia of penis

CLINICAL/SURGICAL PEARLS
- Micropenis is a condition with many causes, most of which are either a form of hypogonadotropic hypogonadism or primary testicular failure
- Thought to be due to deficient 1 synthesis or action after the 1st trimester
- Watch out for large suprapubic fat pad leading to incorrect diagnosis
- Surgery generally not indicated except for associated cryptorchidism
MULTICYSTIC DYSPLASTIC KIDNEY

Daniel Wollin, MD
Ellen Shapiro, MD, FACS

ASSOCIATED CONDITIONS
- Premature hypertrophy of the contralateral kidney (24-46%)
- About 1/3 will have associated congenital anomalies of the heart and urinary tract (CAKUT)
- Contralateral vesicoureteral reflux (~20%) of those with reflux, 40% will have grades III-V
- Contralateral UPJ obstruction (3-12%) and UVJ obstruction (6%)
- Dilated nonobstructed contralateral renal pelvis (common)
- Anomalies of the ipsilateral internal duct structures (15%) including seminal vesicle cysts, Gartner’s cysts, distal ducts, or accessory ducts
- Congenital absence of the vas deferens
- Horseshoe kidney

DIAGNOSIS

HISTORY
At least 65% are detected prenatally

PHYSICAL EXAM
Abdominal mass palpable in 13%

DIAGNOSTIC TESTS & INTERPRETATION
- Urinalysis
- urine microscopy and culture
- Imaging
- US: Multiple noncommunicating cysts of variable size, scarring, or renal parenchymal thinning
- Renal scan: absence of function, or no function on contralateral side
- VCUG: to evaluate for contralateral reflux
- Renal ultrasonography

Pathologic Findings
- Acquired renal cysts
- Autosomal dominant kidney disease
- Cystic congenital mesoblastic nephroma
- Cystic Wilms tumor
- Cysts of the metanephros
- Neuroblastoma (calcifications)
- Renal cysts, scarring, or associated with syndromes (tuberous sclerosis, von Hippel-Lindau, etc.)
- Supernumerary duct junction obstruction (UPJO)
- Vescoureteral reflux (VUR)

TREATMENT

GENERAL MEASURES
- Educate parents about the signs and symptoms of UTI in infancy and childhood especially if reflux status unknown
- Use of nephrectomy to manage MCDK is controversial

MEDICATION
- First Line
- N/A
- Second Line
- N/A
MULTICYSTIC DYSPLASTIC KIDNEY

SURGERY/OTHER PROCEDURES

• Multiple congenital anomalies: May present with mild to severe anomalies of the kidney and urinary tract.

• MCDK occurs as a result of renal maldevelopment due to possible mutation(s) in genes responsible for ureteral bud formation.

• Large cysts of varying sizes present with no identifiable parenchyma; ureter usually atretic.

• Most involute or become significantly smaller; rare enlargement.

• As of 2012, the American Academy of Pediatrics states that contact sport participation is generally OK for children who have only one functional kidney. In a very large published series, none of the kidney injuries were catastrophic or needed surgery.

• Long-term follow-up for hypertension and microalbuminuria by informed pediatrician or family physician; referral to nephrology for renoprotective medications when indicated.

ADDITONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

• Usually excellent in unilateral disease.

• kidneys which remain large, increase in size, or show an increased amount of solid tissue (especially with function).

• May persist after nephrectomy depending on the patient age at onset of hypertension and the presence of CAKUT (see Prognosis).

ADDITIONAL READING

REFERENCES

See Also (Topic, Algorithm, Media)

• Multicystic Dysplastic Kidney Image

• Potter Syndrome/Potter Facies

• Renal Cysts

• Renal Dysplasia, Hypodysplasia, and Hypoplasia

ICD10

Q62.39 Other specified cystic kidney disease

CLINICAL/SURGICAL PEARLS

• MCDK occurs as a result of renal maldevelopment due to possible mutation(s) in genes responsible for ureteral bud formation.

• Large cysts of varying sizes present with no identifiable parenchyma; ureter usually atretic.

• Most involute or become significantly smaller, rare enlargement.

• Almost never require nephrectomy, consider for functioning solid component or increasing size.

• Not associated with increased risk of hypertension during childhood or Wilms tumor in large series.

• Long-term follow-up recommended for hypertension and microalbuminuria especially at puberty and in adulthood.

AS STM 247
MULTIPLE SCLEROSIS, UROLOGIC CONSIDERATIONS
Alana M. Murphy, MD

DESCRIPTION
- Multiple sclerosis (MS) is a neurologic disease causing focal demyelination of white matter in the brain and spinal cord that can impact urinary tract functioning.
- Plaques visible on magnetic resonance imaging (MRI) are inflammatory and often lead to scar tissue deposition. They interfere with conduction of electrical signals resulting in loss of central inhibition of reflex activity and dysfunctional conduction of sensory and motor signals.

EPIDEMIOLOGY
Incidence
- Most commonly presents between ages 20 and 50 yr old.
- Females have 1.5–3 times greater incidence than males.

Prevalence
- 1 in 250 lifetime risk of developing MS in USA
- More common in Caucasians and above 40

RISK FACTORS
- Genetics
  - Increased risk if MS is present in a 1st-degree relative
  - Primary relative with MS confers 20 times risk
  - Identical twin: 300 times increased risk if other twin develops MS
  - Unknown pattern of inheritance

PATHOPHYSIOLOGY (1)
- Spinal cord attack on the central nervous system (CNS) myelin:
  - Focal demyelination with relative axon sparing
  - Histopathology shows perivascular lymphocytic infiltrates, microglial within the white matter, gliosis, and scarring

- Urologic manifestations include urinary frequency, urgency incontinence, voiding symptoms, urinary retention, and sexual dysfunction.

- Detrusor sphincter dyssynergia (DSD) and detrusor overactivity (DO) are common dysfunctions noted on urodynamic studies (UDS).

DIAGNOSIS
HISTORY
- Presence of neurologic symptoms:
  - Vision changes, balance problems, discoordination, numbness, or paresthesia
  - Urologic history: All patients with MS should be screened for urologic problems:
  - Recurrent UTIs
  - Urinary frequency
  - Urgency incontinence
  - Voiding symptoms
  - Urinary retention

PHYSICAL EXAM
- Urologic exam:
  - Testicular and prostate exam in males to rule out neoplasm or infection
  - Pelvic exam in females to assess pelvic support and rule out uterine or vaginal pathology
  - Deep tendon reflexes, proprioception, Babinski nerves (absent in up to 30%)
  - Bulbocavernous reflex to assess function of sacral nerves
  - Pelvic exam in females to assess pelvic support and rule out urethral or vaginal pathology
  - Testicular and prostate exam in males to rule out neoplasm or infection

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CFS for initial MS diagnosis (oligoclonal IgG bands)

Imaging (2,3)
- MRI:
  - Most useful tool for diagnosing MS; diagnostic in 70–95% of cases
  - Increased signal intensity on T2-weighted images in areas of demyelination
  - Upper urinary tract imaging:
  - Rule out presence of hydronephrosis
  - Renal ultrasound (US) is a good screening test
  - Important in patients with known OUS or in patients with indwelling catheters

- Lower tract imaging less commonly performed:
  - Fluoroscopy during UDS can assess for bladder pathology (stones, trabeculation), vesicoureteral reflux, and DSD

ASSOCIATED CONDITIONS
- DSD leading to urinary retention, recurrent UTIs, and impairment in renal function
- Detrusor hyperreflexia due to urinary stasis from incomplete bladder emptying and recurrent UTIs

GENERAL PREVENTION
- No proven methods for prevention

GENERAL MEASURES
- Avoid stressors
- Disease-modifying medications specific to MS can reduce relapses and control some symptoms: biologic agents (natalizumab, and teriflunomide), β interferons, glatiramer acetate, fingolimod, mitoxantrone, and natalizumab
- Remissions can occur spontaneously, making management difficult

DIFFERENTIAL DIAGNOSIS
- Idiopathic overactive bladder
- DSD leading to urinary retention
- Urinary urgency

DIAGnostic Procedures/Surgery
- PVR
  - Urologic specialists to assess bladder capacity, compliance, detrusor function, continence, and detrusor–sphincter coordination
  - Routinely performed with fluoroscopy in MS patients

- Patients with indwelling catheters
  - Assess risk for upper tract deterioration (elevated storage and voiding pressures)
  - May suggest diagnosis of MS in patient with few other neurologic symptoms
  - Need follow-up UDS with change in clinical symptoms

Pathologic Findings
- Deterioration with trabeculation

TREATMENT
- Urologic overactive bladder
- Detrusor hyperreflexia
- Dysfunctional voiding
- Avoid stressors
- Detrusor underactivity or UCO with indwelling catheter

RECOMMENDATIONS
- Urologic examination at diagnosis
- Patients on antipsychotics may be at increased risk
- Lower tract symptoms in MS patients require prompt evaluation
- Patients with MS and indwelling catheters should have a thorough urologic examination

REFERENCES
**PROGNOSIS**

With proper urologic follow-up, renal function can be preserved in most patients.

**COMPLICATIONS**

- Hydrothorax and impairment in renal function due to elevated bladder pressure or voiding pressure
- Urolithiasis due to urinary stasis, indwelling catheters and infection
- Recurrent UTIs
- Urethral erosion from indwelling catheters

**FOLLOW-UP**

### Patient Monitoring

- Upper urinary tract screening is especially important in men, since men with MS often develop high bladder storage pressure and urinary stasis without developing overt urologic symptoms such as incontinence.

### Incontinence, especially in women, can become problematic as the severity of MS progresses.

- Patients with bladder dysfunction secondary to MS can be stratified into low- and high-risk patients:
  - Low-risk patients: Those with normal continence, no UTIs, and complete bladder emptying. These patients do not require frequent upper tract imaging.
  - High-risk patients: Incontinence, recurrent infections, DSD, elevated storage pressures >40 cm H2O, indwelling catheters

- Follow closely for upper tract deterioration, keep lines short, and avoid indwelling catheters.

### Providers’ Approach to Bladder Management in Multiple Sclerosis.

### Ongoing Care

- Stress reduction therapies and acupuncture have been associated with symptom reduction.

### Additional Reading

### Clincial/Surgical Pearls

- Medical therapy and behavioral modification remain the first line of treatment for urinary frequency and urgency incontinence.
- Indwelling injection of botulinum toxin should be used for refractory neurogenic detrusor overactivity.
- Adequate management of lower urinary tract function will lead to preservation of renal function.

### Codes

- ICD-9: 788.31 Urge incontinence
- ICD-10: N29.41 Urge incontinence
- R35.0 frequency of micturition

### References

Myasthenia Gravis, Urologic Considerations

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Myasthenia gravis (MG) is a chronic autoimmune disorder characterized by weakness and early fatigability of the skeletal muscles due to antibody-mediated loss of nicotinic acetylcholine (ACh) receptors (1,2).
- Involvement of the external urinary sphincter is rare but may be vulnerable to dysfunction after thymectomy or resection of the thymus (TURP), explaining the relatively high incidence of post-TURP incontinence in this group (1).
- Although smooth muscle is generally not affected, there are rare reports of detrusor areflexia (4).
- Urologic complaints are uncommon but may include incontinence, urgency, retention, or erectile dysfunction.

EPIDEMIOLOGY

Incidence

- Published estimates of 2–21 cases per million people per year (1,2).
- Prevalence:
  - In patients <40 yr:
    - Male > Female (1:3).
  - In the 5th decade, new cases of MG are evenly split between the genders.
  - After the 5th decade:
    - Male > Female (2:1, 1,2)

RISK FACTORS

- Thymic hyperplasia is observed in 65–75% of patients (1,2).
- MG has been described as a paraneoplastic syndrome related to renal cell carcinoma (RCC) (5), as well as other malignancies (thymoma, lymphoma, lung cancer, Kaposi's sarcoma) (6).

Genetics

- Congenital myasthenic syndromes, a subset of MG, stem from genetic mutations resulting in abnormal neuromuscular transmission (1,2).
- HLA types B8 and DR3 are associated with MG.

PATHOPHYSIOLOGY

- Autoantibodies develop against ACh nicotinic postjunctional receptors (1,2).
- The autoantibodies mechanically block the neuromuscular junction binding site and eventually destroy them.
- Cholinergic nerve conduction to striated skeletal muscle is thus impaired.
- Clinical symptoms begin to develop when the number of ACh receptors is reduced to ~30% of the normal level.

- Smooth and cardiac muscle are not affected.
- The role of the thymus in MG is unclear, but it is suspected to be a site of autoantibody formation.
- A majority of patients with MG have thymic hyperplasia or thymoma.

Many patients improve clinically following thymectomy.

ASSOCIATED CONDITIONS

- Neonatal MG is a transitory disorder resulting from passive maternal antibody transfer to the fetus.
- Congenital myasthenic syndromes result from genetic mutations that lead to abnormal neuromuscular transmission.
- Ocular MG refers to weakness limited to the extracocular muscles and eyelids.

GENERAL PREVENTION

None

DIAGNOSIS

HISTORY

- Reduced exercise tolerance that improves with rest and worsens with warm temperature (e.g., after a hot bath).
- The natural history of MG usually follows a characteristic pattern that initially involves weakness of eyelids and extracocular muscles.
- Difficulty climbing stairs is typical of generalized weakness in MG.
- Weakness is variable and fluctuating, but tends to be worse later in the day.

PHYSICAL EXAM

- Muscle fatigability can be tested for many muscles by repeated action: Ptosis, diplopia, dysphagia, and peripheral muscle weakness.
- “Dropped head syndrome”

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serology tests demonstrate anti-ACh receptor antibodies in ~90% of patients.
- ~30% of patients who test negative for anti-ACh receptor antibodies have antibodies against the MuSK protein.
- Urodynamics:
  - Complete urodynamic evaluation if urologic symptoms are present (4).
  - If bladder dysfunction present, resembles lower motor neuron pattern with variable areflexia or atonia.
- In one UDS series 63% failing to empty completely due to hypercontractile bladders and 6% had complete areflexia.

Pathologic Findings

- None

DIFFERENTIAL DIAGNOSIS

- Acute inflammatory demyelinating polyradiculoneuropathy
- Botulism
- Lambert–Eaton syndrome

TREATMENT

GENERAL MEASURES

- Immediate catheterization for rare cases of refractory detrusor areflexia (4).
- Adjust mealtimes to take advantage of daily periods of relative strength.
- Install railing in household places where it will be needed for support in rising, such as at the bathtub and toilet.
- Use electric toothbrushes and can openers to conserve strength.
- Generalized muscle weakness in the acute setting should prompt careful attention to the possibility of respiratory failure.
- Patients with MG have symptoms worsened by high core or ambient temperature; therefore, muscle strength will likely improve when a fever is treated with antipyretics.
- Urinary tract symptoms, if present, may respond favorably to therapy for MG.

Diagnostic Procedures/Surgery

- Diphenhydramine chloride test: Positive for MG if IV administration unequivocally yields improved strength.
- Repetitive nerve stimulation
- Single-fiber electromyography
- Complete urodynamic evaluation if urologic symptoms are present (4).

Imaging

- Chest computed tomography (CT) to rule out thymoma.
- If level of suspicion is high, CT abdomen to rule out RCC (5).

Urodynamics:

- If bladder dysfunction present, resembles lower motor neuron pattern with variable areflexia or atonia.
- In one UDS series 63% failing to empty completely due to hypercontractile bladders and 6% had complete areflexia.
MYASTHENIA GRAVIS, UROLOGIC CONSIDERATIONS

MEDICATION
First Line
- Cholinesterase inhibitors (neostigmine, pyridostigmine) provide temporary strength improvement in patients with MG.
- Corticosteroids can produce rapid improvements in MG but are associated with numerous dose-dependent side effects.

Second Line
- Plasmapheresis is reserved for short-term treatment in response to myasthenic exacerbations or crises.
- Intravenous immunoglobulin (IgG) also provides short-term improvements in strength during myasthenic exacerbations or crises as an alternative for patients who are poor plasmapheresis candidates because of vascular access issues.
- Immunosuppressive agents (azathioprine, cyclophosphamide, cyclosporine, methotrexate, mycophenolate mofetil, rituximab, tacrolimus) for steroid-sparing protocols, or for refractory disease.

SURGERY/OTHER PROCEDURES
- If surgical intervention for bladder outlet obstruction secondary to benign prostatic hyperplasia (BPH) is being considered, some advocate suprapubic prostatectomy to reduce risk of incontinence.
- Thymectomy results in complete remission in 35% of cases and clinical improvement in 85% of patients.

OTHER TREATMENTS
- Radiation Therapy: N/A
- Additional Therapies: β-Agonist and anticholinergic bronchodilators can reduce bronchospasm and respiratory distress resulting from cholinergic medications.

Ongoing Care

PROGNOSIS
- Most (96%) of patients have normal lifespan when appropriate medical care involving cholinesterase inhibitors, plasmapheresis, and immunosuppressive agents is given.
- Thrombosis results in complete remission in about 1/3 of patients, but the postsurgical prognosis is otherwise highly variable.

COMPLICATIONS
- Post-TURP Incontinence
- Respiratory failure
- Cholinergic crisis from excessive use of cholinesterase inhibitors

FOLLOW-UP
- Patient Monitoring: Patients with MG should be followed by a neurologist with urology referral as needed.

ADDITIONAL TREATMENT
- Radiation Therapy: N/A
- Additional Therapies: β-Agonist and anticholinergic bronchodilators can reduce bronchospasm and respiratory distress resulting from cholinergic medications.

Complementary & Alternative Therapies: N/A

ADDITIONAL READING

CODES
- ICD-9: 358.00 Myasthenia gravis without (acute) exacerbation
- 788.30 Urinary incontinence
- 788.63 Urgency of urination

- ICD-10: G70.00 Myasthenia gravis without (acute) exacerbation
- N39.41 Urge incontinence
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS
- Patients with MG may develop voiding dysfunction, most commonly detrusor areflexia resulting in urinary retention.
- Urinary incontinence may develop after TURP.
- Urologic symptoms may be improved by systemic MG therapy, although specific therapy for urologic complications, such as urinary retention or incontinence, may need to be instituted.
**BASICS**

**DESCRIPTION**
- Myelodysplasia (spinal dysraphism, neural tube defect) is a very broad term encompassing a large heterogeneous group of congenital vertebral column defects that result from defects that occur during neural tube closure.
- Group of developmental abnormalities that can be open (meningocele, myelomeningocele, lipomyelomeningocele) or closed (spina bifida occulta, posterior meningocele, lipomyeloneuromuscular dysplasia).
- Primary functional defects can be lower limb paralysis and sensory loss, bladder and bowel dysfunction, and cognitive dysfunction.
- Affected children often have varying degrees of neurogenic bladder dysfunction.

**ALER T**
- Patients with myelodysplasia have a high incidence of latex allergies. From birth, parents need to be educated in latex precautions.

**EPIEDIOLOGY**

**Incidence**
- Spinal dysraphism: 1 per 1,000 births in USA previously.
- Spina bifida occulta: 5–10% of the general population; most cases are found incidentally.

**RISK FACTORS**
- Maternal folate deficiency during pregnancy.
- Family history: Incidence for mother with one affected child is 10–50/1,000 live births; also 2nd and 3rd degree affected relative.
- Poor pregnancy check or absence.
- Exposure to high temperatures in early pregnancy (fever or hot tub).
- Traumatic exposure to valproate or carbamazepine.
- Low vitamin 8-12 levels.
- Chromosomal anomalies (13 and 18, triploidy, and single-gene mutations).

**GENETICS**
- Genes involved in folate-homocysteine metabolism and transport (see Risk Factors).

**PATHOPHYSIOLOGY**
- Increased maternal blood AFP (α-fetoprotein) at 16 wk can indicate the presence of an NTD (neural tube defect).
- Spinal cord begins normal development on day 18 of gestation.
- The canal closes in a cephalocaudal direction; complete closure day 35 of gestation.
- Basis mechanism of dysraphism undifferentiated stem cells states can be subdivided:
  - Spina bifida occulta: The mildest form. No overt signs of spinal abnormality; may be associated with tethering of the spinal cord and often associated with a low-lying conus (below L2–L3) usually detected by plain x-ray, demonstrating open vertebral bodies.
  - Posterior meningocele, myelocystocele, and lipomyelomeningocele are closed defects associated with a skin-covered back mass.
  - Meningocele: The meninges or dural sac, but no significant neural elements, extend beyond the vertebral canal. Mostly normal lower extremity.
  - Myelomeningocele: The nerves and spinal cord are exposed through an opening in the spinal column, mengines, and skin. Significant neurologic defects (paraplegia, urinary incontinence) are usually associated.
  - Lipomyelomeningocele: Fatty tissue along with cord structures extend with protruding sac.

**ASSOCIATED CONDITIONS**
- Clinical anomalies: Local neurosurgical anomalies.
- Hydrocephalus/Arnold–Chiari malformation.
- Imperforate anus.
- Lipoma.
- Sacral agenesis.
- Urogenital anomalies (renal defects, renal agenesis, cardiac defects, tracheo-esophageal fistula, renal anomalies, and limb anomalies).

**GENERAL PREVENTION**
- Folic acid 0.4 mg/d in all women of childbearing age.
- Maternal folate deficiency during pregnancy.
- Begin 2 mo before planned conception or at time of pregnancy.

**DIAGNOSIS**

**HISTORY**
- Review medical and developmental history.
- Most patients now diagnosed prenatally.
- Older patients commonly present with urinary and bowel incontinence.
- Change in bowel habits or guilt, onset of leg or back pain, presence of seizures, or other neurologic symptoms may suggest subsequent spinal cord tethering.

**PHYSICAL EXAM**
- Abnormalities: size, body habitus, gait, dexterity, muscular, and neurologic development.
- Genitalia: Presence or absence of hypospadias, cryptorchidism, labial/abnormalities.
- Rectal exam: Perianal sensation, rectal tone, fecal impaction.
- Back exam: When present, spinal canal deformities, kyphoscoliosis, and scoliosis may be noted.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urodynamics, urine culture, basic metabolic panel with high-grade reflux or hydrocephrosis.

**Imaging**
- 15–20% of neonates have abnormality of upper tract: 1st studied.
- Plain abdominal x-rays:
  - May show structural urologic anomalies or evaluate for partial or complete sacral agenesis.
  - May visualize stones or fecal impaction.
- Renal US (abdominal):
  - Determine baseline of urinary tract should be performed shortly after birth. Important to repeat after back closure prior to discharge.
  - Assess for hydrocephrosis, hydronephrosis, and PVR.
  - Postvoid residual: If patient voids spontaneously.
  - Voiding cystourethrography (VCUG):
    - Assess for vesicoureteral reflux, bladder wall thickness, bladder capacity, and neurogenic bladder.
- Dimercaptosuccinic acid (DMSA) renal scan in select cases:
  - Including high-grade reflux, renal scarring, and solitary functioning kidney.
- Magnetic resonance imaging (MRI):
  - Assess spinal cord and vertebral anomalies in patients with suspected occult spinal dysraphism or a “closed” lesion.
  - Spinal sonogram useful in the diagnosis of occult spinal dysraphism.

**Diagnosis Procedure/Surgery**

**Uninduced studies (USS):** Fill rate based on average bladder capacity in milliliters (24.5 x age + 62) divided by 10 is the rate of filling the bladder with warm saline.
- Assess bladder capacity, volume, and pressure at abdominal and detrusor leak points (compliance), pressure when reflux, if present, is observed.
- Detrusor overactivity, detrusor spasticity, and epispadias.

**Pathologic Findings**
- See Pathophysiology.

**DIFFERENTIAL DIAGNOSIS**
- Other causes of neurogenic bladder (see Chapter on Neurogenic Bladder, general).
- Tethered cord syndrome.

**MYELODYSPLASIA (SPINAL DYSRAPHISM), UROLOGIC CONSIDERATIONS**

Blake A. Wynia, MD, MPH
Ellen Shapiro, MD, FACS

252
TREATMENT

GENERAL MEASURES (1,2,3)
- Urgent neurological intervention is critical for open defects, which may lead to hydrocephalus.
- Upper tract preservation is the primary goal with the achievement of continence at an appropriate age.
- Incontinence bladder emptying on significant upper tract hydroprostatic/hydronephrosis is not usually performed.
- Clean intermittent catheterization (CIC) for detrusor filling pressures >30-40 mm H2O. May often require the addition of anticholinergic therapy (see Medication).
- Colostomy, vesicostomy or urethral dilation to lower emptying pressures not usually performed.

MEDICATION

First Line
- Anticholinergics: Decrease detrusor overactivity, improve bladder compliance and functional capacity.
  - Oxybutynin 0.2 mg/kg BID; should be initiated early in life when indicated to prevent upper tract deterioration secondary to poor detrusor compliance and DDS.
  - Tolterodine 0.1 mg/kg BID to a maximum of 240 mg BID; avoid acting forms when older.
- Almost always used in conjunction with CIC.
- Side effects: Headaches, dry mouth, flushing of skin, abdominal discomfort, blurred vision.
- Prophylactic antibiotics considered for reflux.

Second Line
- α-sympathomimetic, α-sympatholytic, smooth muscle relaxants.
- Imipramine 0.7 mg/kg BID with maximum dosing of 2 α-sympathomimetic; consider prematurity EKG

SURGERY/OTHER PROCEDURES
- When pharmacotherapy and CIC do not result in favorable bladder dynamics and/or continence in older patients, consider:
  - Cystoscopy and botulinum A toxin injection.
  - Bladder augmentation usually with creation of continent catheterizable stoma since many of the children are wheelchair bound; wait until the child is 5-6 yr old for continence if upper tracts not deteriorating and bladder is not hostile.
  - Reflux surgery for high-grade reflux.
  - Bladder neck reconstructions.
  - Young-Owens-Leadbetter, Kropp, Papi-Salle modification, bladder neck closure.
  - Fecal diversion, antireflux and/or artificial urinary sphincters.
  - Bowel incontinence.
- If oral laxatives, enemas/irrigation, and rectal suppositories do not result in social bowel continence consider MAPE procedure selectively.

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
- Neurourologic evaluation of the bladder via intravesical electrical stimulation, sacral nerve stimulation, transcutaneous stimulation, and biofeedback. All of unknown efficacy.
- Tissue-engineered bladder augmentation (experimental).
- Artificial somatic-autonomic reflux pathway (experimental).

ONGOING CARE

PROGNOSIS
- Self-performance of CIC is likely in school-aged children with supervision.
- Regular monitoring for silent upper tract deterioration including renal isonogram and VUDs.
- Elective and prophylactic distention.
- Delivery concerns especially at the end of gestation in myeloblastosis patients with bladder or bladder neck reconstruction.

COMPlications
- Incisional wound infection requires the addition of skin ulceration due to ammonia burns; consider delaying circumcision until 1 year of age.
- Renal insufficiency.
- Symptomatic UTIs.
- Seizure disorders.
- Musculoskeletal problems (spina bifida, club foot, others).

FOLLOW-UP
- Patient Monitoring
  - Close follow-up with pediatric urology and neurology from infancy and throughout childhood is required to achieve urinary and bowel continence. Annul US and VUDs when continent with stable upper tracts.
- Patient Resources
  - Myelodysplasia Association.

- 789.30 Urinary incontinence, unspecified.
- 441.20 Myelodysplastic syndrome, unspecified.
- 311.9 Neurovascular dysfunction of bladder, unspecified.
- 932 Unspecified urinary incontinence.

PEARLS
- Affects children often have varying degrees of neurogenic bladder and bowel dysfunction.
- First-line treatment consists of CIC for elevated PVR and anticholinergics when VUD testing suggests poor detrusor compliance and/or detrusor overactivity with or without upper tract deterioration.
- Botulinum A toxin injections, bladder augmentation, antireflux procedures and/or bladder neck procedures performed to protect upper tracts and achieve urinary continence.
NEPHROCALCINOSIS, ADULT

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

ASSOCIATED CONDITIONS

- Nephrolithiasis
- Hypercalciuric states:
  - Primary hyperparathyroidism (most common cause in adults)
  - Scurvy
  - Vitamin D intoxication
  - Multiple myeloma
  - Tuberculosis
- Hyperphosphaturic states:
  - Fanconi syndrome
  - Distal renal tubular acidosis
  - Medullary sponge kidney
  - Inherited tubular defects (eg, Bartter syndrome)
- Chronic pyelonephritis (eg, primary aldosteronism)
- Chronic immobilization
- Renal oxalosis
- Hyperuricosuria
- Other disorders:
  - Long-term suppressive antimicrobial therapy

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Used to identify underlying causative disorder
- Serum studies:
  - Calcium, phosphate, albumin
  - Electrolytes
  - BUN, Cr
  - Parathyroid hormone (PTH) levels
  - Thyroid stimulating hormone (TSH) levels
  - CBC
- Urine studies:
  - Urolithiasis with microscopy + i–j urine culture (if indicated)
  - 24 hr urine collection

Imaging
- Can be detected on:
  - Abdominal radiograph
    - Usually only if attenuation > 100 Hounsfield units and slice > 2 mm
  - Medullary nephrocalcinosis:
    - Stippled calcifications in renal pyramids
  - Cortical nephrocalcinosis:
    - Thin peripheral band with peripelvic extension; thin, peripheral calcific tracts, or diffuse punctuate calcifications
- Ultrasonography
  - Hyperdense areas with or without acoustic shadowing
- Computed tomography
  - Diffuse punctate calcifications diagnostic of CaPhos

DIAGNOSIS

HISTORY
- Most cases are asymptomatic ( incidental finding on imaging)
- Occasionally present with symptoms related to underlying cause or associated condition
  - Nausea, decreased appetite, abdominal pain, malaise, polydipsia, lethargy (hypercalcemia)
  - Fatigue, edema, mental status changes, anorexia (renal failure)
  - Renal colic, hematuria (nephrolithiasis)
- Review past medical history and medications

PHYSICAL EXAM
- Nonspecific; many patients are asymptomatic
- Physical findings otherwise a manifestation of underlying disorder

PATHOPHYSIOLOGY

- Increased urinary excretion of calcium, phosphate, and/or oxalate
- May occur with or without hypercalciuria
- Calcium oxalate (CaOx) and calcium phosphate (CaPhos) crystals result from urinary supersaturation
- CaOx and CaPhos crystals precipitate, aggregate, and move to interstitium
- May result in acute or chronic renal damage and/or lead to calculus formation
- Renal ischemia or injury may augment nucleation of CaOx or CaPhos crystals

ASSOCIATED CONDITIONS

- Nephrolithiasis
- Hypercalciuric states:
  - Primary hyperparathyroidism (most common cause in adults)
  - Scurvy
  - Vitamin D intoxication
  - Multiple myeloma
  - Tuberculosis
- Hyperphosphaturic states:
  - Fanconi syndrome
  - Distal renal tubular acidosis
  - Medullary sponge kidney
  - Inherited tubular defects (eg, Bartter syndrome)
- Chronic pyelonephritis (eg, primary aldosteronism)
- Chronic immobilization
- Renal oxalosis
- Hyperuricosuria
- Other disorders:
  - Long-term suppressive antimicrobial therapy

PATHOPHYSIOLOGY

- Increased urinary excretion of calcium, phosphate, and/or oxalate
- May occur with or without hypercalciuria
- Calcium oxalate (CaOx) and calcium phosphate (CaPhos) crystals result from urinary supersaturation
- CaOx and CaPhos crystals precipitate, aggregate, and move to interstitium
- May result in acute or chronic renal damage and/or lead to calculus formation
- Renal ischemia or injury may augment nucleation of CaOx or CaPhos crystals
Nephrocalcinosis, Adult

Differential Diagnosis
- Nephrocalcinosis
  - Renal calculi, associated with:
    - Chronic ureteropelvic junction obstruction or urolithiasis
    - Renal infection
    - Renal trauma
  - Dystrophic calcifications, associated with:
    - Renal tuberculosis
    - Congenital cystic kidney
  - Renal artery calcifications
  - Calcification associated with spinal injury

Treatment

General Measures
- Treatment directed at underlying etiology
- No specific treatment prevents progression
- Early treatment of reversible causes of renal injury important
- Reduce urinary concentration and increase solubility of calcium, phosphate, and/or oxalate
- Increase fluid intake
- Goald urine output > 2 L
- If hypercalcemia:
  - Restrict animal protein intake (max 0.7 g/kg)
  - Restrict sodium intake (< 100 mEq/d)
  - If hypocalcemia and urine pH <7:
    - Potassium citrate (titrate to normal urinary citrate)

Medication

First Line
- Must be tailored to underlying etiology (eg, for hyperparathyroidism, resection of adenoma, treatment of renal tubular acidosis, etc.)

Second Line
- N/A

Surgery/Others Procedures
- Surgical intervention may be required, particularly if calcification obstructs collecting system
  - Endourologic management
  - May use in diagnosis (direct visual inspection)
  - May treat with flexible ureteroscopy/nephroscopy with laser or electrohydraulic lithotripsy (EHL)
  - Ununinvasive laser papillotomy may be safe and effective
  - Important to distinguish nephrocalcinosis from nephrolithiasis

Imaging if symptomatic
- Labs to monitor known metabolic abnormalities
- Imaging if symptomatic

Patient Resources
- http://www.nephron.com/article/000492.htm

References

ICD-9
- 275.42 Hypercalcemia
- 275.49 Other disorders of calcium metabolism

ICD-10
- N29 Other disorders of kidney and ureter in diseases classified elsewhere

Clinical/Surgical Pearls
- Important to distinguish nephrocalcinosis from nephrolithiasis
- Management directed at underlying cause of disorder
- Surgery is indicated in patients with chronic renal pain, sepsis, or failure to thrive

Ongoing Care
- Depends on underlying etiology
- Most do not progress to end-stage renal failure

Complications
- Nephrocalcinosis
- Obstructive urolithiasis
- May be associated with spondylolysis
- Renal infection
- Renal scarring
- Defects in renal tubular function
- Acute renal failure
- Chronic renal failure

Follow-Up
- Patient Monitoring
  - Urinalysis, 24-hr urine collection
  - Renal function testing
  - Serum Ca
  - Labs to monitor known metabolic abnormalities
  - Imaging if symptomatic

Additional Reading
Nephrotic Syndrome

Michael Pierotti, MD

**Basics**

**Description**
- Nephrotic syndrome refers to a specific renal disease with a distinct constellation of clinical and laboratory features:
  - Proteinuria (>3.5 g/dl)
  - Hypoalbuminemia (<3 g/dl)
  - Peripheral edema
  - Hypertension and thrombotic disease frequently seen
- Nephrotic syndrome (NS) can be caused by specific renal diseases or systemic diseases such as diabetes, lupus and others.

**Epidemiology**
- **Incidence**
  - **Children:** 2/100,000 new cases / year
  - **Adult:** 3/100,000 new cases / year
- **Prevalence** N/A

**Risk Factors**
- Primary renal disease (minimal change disease predominant cause in children)
- Underlying systemic disease in 30% of adults with NS including diabetes mellitus, amyloidosis, systemic lupus erythematosus
- Infection: Streptococcus, hepatitis, mononucleosis, syphilis, tuberculosis, HIV
- Medications: NSAIDs, interferons, bisphosphonates, lithium, gold, captopril, penicillamine, tyrosine kinase inhibitors
- Malnutrition

**Genetics**
- **Rare cause**
  - 2-8% of cases are familial
  - Finnish type congenital nephritic syndrome is inherited as autosomal recessive

**Pathophysiology**
- Severe proteinuria is due to abnormal permeability of the glomerular basement membrane (GBM) (1).
- FSBNs are seen as serum albumin falls below 2.5 g/dl.
- Proteinuria can be selective or nonselective.
- Edema results from primary salt retention and secondary decreased plasma oncotic pressure.
- Hypertension is secondary to increased hepatic synthesis from low oncotic pressure and urinary loss of regulatory proteins.
- Hypercoagulable state is likely due to loss of antithrombin III in urine.

**Associated Conditions**
- Membranous nephropathy (24%)
- Minimal change disease (11%)
- Lupus (14%)
- Focal segmental glomerulosclerosis (12%)
- Membranoproliferative glomerulonephritis (7%)
- Amyloidosis (8%)
- IgA nephropathy (8%)

**General Prevention**
- Avoidance of risk factors
- Treating conditions that may cause NS

**Diagnosis**

**History**
- Symptoms of fluid/sodium retention:
  - Dyspnea/orthopnea secondary to pleural effusion
  - Peripheral edema, especially at end of day
  - Periorbital edema, especially on awakening

**Physical Exam**
- Along with signs of fluid retention, patients may have signs of systemic disease causing NS
  - Fever
  - Rash (eg, butterfly rash of SLE), palmar, edema, lymphadenopathy
  - Ophthalmic exam: Uveitis in sarcoid, diabetic retinopathy
  - Skin exam: Rash (butterfly rash of SLE), palmar, edema, lymphadenopathy
  - Ophthalmic exam: Uveitis in sarcoid, diabetic retinopathy
  - Heartburn exam: Endocarditis, pleural effusion
  - Abdominal exam: Masses, ascites
  - Neurologic exam: Diabetic neuropathy, CNS lesion, mononeuritis multiplex

**Laboratory**
- Blood chemistry: BUN, Cr, comprehensive metabolic panel
- CBC
- **Albuminuria** detected by SSA; Protein is precipitated in urine by the addition of sulfosalicylic acid (SSA).

**Diff erential Diagnosis**
- Congestive heart failure
- Cirrhosis
- Malnutrition
- Protein-losing enteropathy

**Urinary Analysis and Microscopy**
- Marked proteinuria causes urine to foam.
- Albuminuria detected by dipstick, all proteinuria detected by SSA.

**Pathologic Findings**
- Minimal change glomerulopathy
- Membranous glomerulopathy
- Focal segmental glomerulosclerosis
- Membranoproliferative glomerulonephritis
- Diabetic glomerulosclerosis
- Fibrillary glomerulonephritis
- Light chain deposition disease

**Proteinuria (multiple myeloma)**
- Characteristic dipstick reading of 3+ to 4+ in NS patients
- Glycosuria: Suggests diabetes mellitus as possible cause of NS
- Hematuria common (usually microscopic)

**Imaging**
- Renal ultrasound: Increased echogenicity of renal parenchyma
- Screening for underlying malignancy with CT scan

**Differential Procedures/Surgery**
- Renal biopsy
TREATMENT

GENERAL MEASURES
- Sodium restriction (2-3 g/day)
- Protein restriction
- BF control
- Maintenance of fluid balance

MEDICATION
First Line
- ACE inhibitors (captopril, enalapril, ramipril, others) or Angiotensin II receptor blockers (losartan, irbesartan, telmisartan others)
- Should not be used concurrently due to risk of hypotension and worsening renal function
- Monitor for hypotension, hyperkalemia, or worsening renal function
- Common ACE-I side effects include cough, angioedema, or allergy

Second Line
- Statin therapy
  - Total LDL < 100 and triglyceride < 150
  - Side effects include myalgia, liver dysfunction, GI disturbance, and rash
- Corticosteroids for primary idiopathic or minimal change disease (3)

Second Line
- Cytotoxic agents (cyclophosphamide, chlorambucil, leflunomide)
- Second Line
- Cytotoxic agents (cyclophosphamide, chlorambucil, leflunomide)

ADDITIONAL TREATMENT
SURGERY/OTHER PROCEDURES
- Dialysis
- Renal transplantation

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Anticoagulation for thrombosis

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Prognosis depends on age, race, pathology, presence of HTN, underlying systemic disease, degree of renal dysfunction, and degree of proteinuria.
- Minimal change disease in children has an excellent prognosis.
- Prognosis of the other glomerulopathies much more variable.
- Prognosis of secondary NS depends on the systemic diseases causing the NS.

COMPLICATIONS
- Acute kidney failure
- Atherosclerosis, hyperlipidemia, cardiovascular disease
- Chronic kidney disease
- Congestive heart failure
- Malnutrition
- Pneumococcal pneumonia and other infections
- Pulmonary edema
- Arterial and venous thrombosis (particularly deep vein and renal vein thrombosis)

Prognosis of secondary NS depends on the systemic diseases causing the NS.
Prognosis of the other glomerulopathies much more variable.
Minimal change disease in children has an excellent prognosis.
Prognosis depends on age, race, pathology, presence of HTN, underlying systemic disease, degree of renal dysfunction, and degree of proteinuria.
Minimal change disease in children has an excellent prognosis.
Prognosis of the other glomerulopathies much more variable.
Prognosis of secondary NS depends on the systemic diseases causing the NS.

NEUROBLASTOMA
Nilay M. Gandhi, MD
Arthur L. Burnett, II, MD, MBA, FACS

PATHOGENESIS
- Determined by tumor site origin, metasasis, and presence of pheochromocytoma syndromes
- Likely failure of persistent primitive ganglion cells to respond to normal signals
- Spinal cord, sympathetic ganglia involvement:
  - Urinary retention, constipation, extremity paresis, Horner syndrome
  - Presence of metastasis:
    - Fever, lethargy, weight loss, bony pain, pallor
    - Bone metastasis (children and adults)
    - Liver metastasis (younger children)
- Active biochemical products:
  - 90% produce catecholamines
  - Paraganglionic hyperplasia (HTN), palpitation, flushing, headache
- Neuroblast: acid (NTA) in poorly differentiated tumors
- Vanillylmandelic acid (VMA) in well-differentiated tumors

ASSOCIATED CONDITIONS
- Other disorders of neural crest derived cells:
  - Hirschsprung disease
  - Neurofibromatosis type 1
- Congenital normal hypertension syndrome

GENERAL PREVENTION
- Screening with urinary catecholamines is not necessary
- 24-hr urinary VMA and NTA
- Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- Ferritin: Elevation in advanced disease
- 40–50% of patients (must be > 3 standard deviations)

IMAGING
- Paravertebral tumor compressing spinal cord
- Bone metastasis (costochondral, rib)
- Blurry hypodense subcutaneous nodules
- Skin metastasis, "blueberry muffin" spots
- Acute myeloid encephalopathy
- Raccoon’s eyes
  - Upper eyelid hemangiom (periorbital metastasis)
- Skull metastasis
- Familial neuroblastoma

DIAGNOSTIC TESTS & INTERPRETATION
- 24-hr urinary VMA and NTA
- Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- Ferritin: Elevation suggests liver involvement
- PENT: Elevation in advanced disease
- 40–50% of patients (must be > 3 standard deviations)
- 5% patients (catecholamines sequestered)

PATHOPHYSIOLOGY
- Determined by tumor site origin, metasasis, and presence of pheochromocytoma syndromes
- Likely failure of persistent primitive ganglion cells to respond to normal signals
- Spinal cord, sympathetic ganglia involvement:
  - Urinary retention, constipation, extremity paresis, Horner syndrome

  - Upper eyelid hemangiom (periorbital metastasis)
- Skull metastasis
- Familial neuroblastoma

DIAGNOSTIC TESTS & INTERPRETATION
- 24-hr urinary VMA and NTA
- Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- Ferritin: Elevation suggests liver involvement
- PENT: Elevation in advanced disease
- 40–50% of patients (must be > 3 standard deviations)
- 5% patients (catecholamines sequestered)

PATHOPHYSIOLOGY
- Determined by tumor site origin, metasasis, and presence of pheochromocytoma syndromes
- Likely failure of persistent primitive ganglion cells to respond to normal signals
- Spinal cord, sympathetic ganglia involvement:
  - Urinary retention, constipation, extremity paresis, Horner syndrome
  - Presence of metastasis:
    - Fever, lethargy, weight loss, bony pain, pallor
    - Bone metastasis (children and adults)
    - Liver metastasis (younger children)
- Active biochemical products:
  - 90% produce catecholamines
  - Paraganglionic hyperplasia (HTN), palpitation, flushing, headache
- Neuroblastoma:
  - Acid (NTA) in poorly differentiated tumors
  - Vanillylmandelic acid (VMA) in well-differentiated tumors

ASSOCIATED CONDITIONS
- Other disorders of neural crest derived cells:
  - Hirschsprung disease
  - Neurofibromatosis type 1
- Congenital normal hypertension syndrome

GENERAL PREVENTION
- Screening with urinary catecholamines is not necessary
- 24-hr urinary VMA and NTA
- Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- Ferritin: Elevation suggests liver involvement
- PENT: Elevation in advanced disease
- 40–50% of patients (must be > 3 standard deviations)

IMAGING
- Paravertebral tumor compressing spinal cord
- Bone metastasis (costochondral, rib)
- Blurry hypodense subcutaneous nodules
- Skin metastasis, "blueberry muffin" spots
- Acute myeloid encephalopathy
- Raccoon’s eyes
  - Upper eyelid hemangiom (periorbital metastasis)
- Skull metastasis
- Familial neuroblastoma

DIAGNOSTIC TESTS & INTERPRETATION
- 24-hr urinary VMA and NTA
- Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- Ferritin: Elevation suggests liver involvement
- PENT: Elevation in advanced disease

- Blurry hypodense subcutaneous nodules
- Skin metastasis, "blueberry muffin" spots
- Acute myeloid encephalopathy
- Raccoon’s eyes
  - Upper eyelid hemangiom (periorbital metastasis)
- Skull metastasis
- Familial neuroblastoma
Pathologic Findings
- Gross: Solid/cystic vascular, poorly encapsulated purple mass
- Histology:
  - Small round blue cells
  - Mitosis-Karyorrhexis index is prognostic
  - Homer-Wright pseudorosettes
- Histopathologic markers:
  - N-MYC
  - DNA ploidy
  - Shimada classification (stroma poor/rich)
  - S-stage (based on age, histologic maturation, mitotic rate)
  - Stroma-rich (nodular, intermediate, well differentiated)
- Neurop-specific enolase (NSE) staining is specific for neuroblastoma
- Periodic acid-Schiff (PAS) staining can distinguish gangliocytic

DIFFERENTIAL DIAGNOSIS
- Ganglioneuroma (benign form)
- Ganglioneuroblastoma (intermediate between ganglioneuroma and neuroblastoma)
- Extra-abdominal mass in childhood:
  - Wilms tumor
  - Phaeochromocytoma
  - Rhabdomyosarcoma
  - Synovial sarcoma
  - Teratoma
  - Intra-abdominal mass in childhood:
    - Ganglioneuroma and neuroblastoma
    - Histopathologic markers:
      - Histology:
        - Gross: Solid/cystic vascular, poorly encapsulated purple mass
        - S-stage (based on age, histologic maturation, mitotic rate)
      - Shimada classification
      - Histopathologic markers:
      - S-stage (based on age, histologic maturation, mitotic rate)

TREATMENT

GENERAL MEASURES
- Multimodal treatment approach including surgery, chemotherapy, radiotherapy, and/or bone marrow or stem cell transplantation
- Nearly all stage 4s patients spontaneously resolve (observation)
- INSS surgical stage and more recently the International Neuroblastoma Risk Group (INRG) risk assessment system dictates treatment (3)

MEDICATION

First Line (4)
- Low risk: favored surgical failure
  - Cyclophosphamide, Adriamycin, and Cisplatin/VM-26 in low-dose cycles
- Intermediate risk: Induction with Cyclophosphamide and Adriamycin with or without radiotherapy
  - High risk: CsA, CsA, Adriamycin, VM-26, Doxorubicin, Cisplatin, Etoposide in various combinations
- Second Line
  - Intermediate risk: Cisplatin/VM-26
  - High risk: Alternative use of above listed combinations

SURGERY/OTHER PROCEDURES
- Low stage stages 1, 2, or 4 with age <1 yr or >1 yr with favorable pathology:
  - Surgery or resection
  - Chemotherapy indicated if recurrence, N-MYC amplification, or unfavorable histology
- Intermediate risk (stage 1a: <1 yr or >1 yr with favorable pathology, or stage 4: <1 yr):
  - Surgery + Multimodality chemotherapy
- High risk (stage 2 with age >1 yr with unfavorable histopathology, or stage 3, 4, 4v with N-MYC amplification regardless of age):
  - Intensive chemotherapy with or without bone marrow ablation and repaired surgery

ADDITIONAL TREATMENT

Radiation Therapy
- Reserved for primary or secondary chemotherapy failures in low-risk patients
- Indicated for local control in bulky stage 3 or advanced stage 4
  - Avoid if spinal cord compression due to adverse effects on spine growth
- Intermittent radiation therapy not better than external beam irradiation

Additional Therapies
- Bone marrow transplantation
- Complementary & Alternative Therapies (5)
  - 13-cis-retinoic acid improves 5-yr overall survival (OS) in children with advanced stage disease after transplantation or intensive chemotherapy
  - Epothilone B: MIBG targeted delivery for metastatic disease
  - Anti-GD2 antibodies (research pending)

ONGOING CARE

PROGNOSIS
- Dependent on risk status
  - Low risk: Resection is curative, >97% 5-yr OS
  - Intermediate risk: neoadjuvant chemo followed by >50% resection, 70–90% 5-yr OS
  - High risk: Neoadjuvant chemo 4 cycles (vastage after 2 cycles), >50% resection, radiation, peripheral stem cell transplant, nononstrosis, 20–40% 5-yr OS
  - Better survival in nonadrenal primary tumors
  - Shimada classification
    - S-stage: <10% survival

COMPLICATIONS
- Dumbbell neuroblastoma with spinal cord compression
  - Best treated with chemotherapy
- Neurosurgical intervention only for emergent decompression
- Associated with tumor presentation and with treatment modalities

FOLLOW-UP

Patient Monitoring
- Low risk:
  - Imaging + lab markers 1–2 mo after therapy, every 6 mo for 5 yr, then annually after 5 yr
  - Intermediate risk:
  - Imaging + lab markers 1–2 mo after therapy, every 1–3 mo for 1st yr, then every 4–6 mo for 2–5 yr, then annually after 5 yr
  - High risk:
  - Imaging + lab markers 1–2 mo after therapy, every 1–3 mo for 5 yr, every 6 mo after 5 yr

Patient Resources

NEUROGENIC BLADDER, GENERAL CONSIDERATIONS
Alana M. Murphy, MD

BASICS

DESCRIPTION
Neurogenic bladder (NGB) is a general term used to describe dysfunction of the urinary bladder due to disease of the central nervous system (CNS) or peripheral nerves involved in the control of urine storage and evacuation.

Epidemiology
Incidence
Difficult to determine incidence due to multiple etiologies.

Prevalence
- Prevalence of voiding dysfunction by specific disease of the central nervous system (CNS) or neurogenic bladder (NGB) is a general term used to describe dysfunction of the urinary bladder due to CNS lesions (1):
  - Transverse myelitis
  - Spinal cord injury
  - Parkinson disease
  - Normal-pressure hydrocephalus
  - Multiple sclerosis
  - Cerebrovascular accident
  - Impaired sphincteric function
  - Impaired bladder sensation
  - Detrusor underactivity
  - Suprapontine: Lesions between pontine and sacral micturition centers:
  - Function: Coordinates sphincter relaxation during bladder contraction
  - Interruption of sacral reflex arc; no detrusor contraction
  - Detrusor underactivity or acontractility

Pathophysiology
- CNS lesions (1):
  - Suprapontine:
    - Function: Inhibits sacral micturition center
  - Detrusor overactivity (DO) due to loss of inhibition of sacral micturition center
  - Pontine micturition center:
    - Function: Coordinates sphincter relaxation during bladder contraction
  - Lesions between pontine and sacral micturition centers are associated with DO and detrusor sphincter dyssynergia (DSD)
- Sacral micturition center:
  - Function: Mediates reflex and voluntary bladder contractions
  - Detrusor underactivity or incontinence

Associated conditions
- CNS lesions (1):
  - Variable voiding dysfunction
  - Detrusor overactivity
  - Impaired bladder sensation
  - Impaired sphincteric function

Diagnosis
History
- Neurologic disease: Onset, duration
- Diabetes mellitus
- Congenital disorders:
  - Neonatal or newborn: Neonatal or newborn
  - Secondary damage: Pressure, infection, urolithiasis
  - Loss of CNS inhibition neurogenic lower urinary tract dysfunction

Urodynamics (UDS): Necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction.

Digital rectal exam:
- Prostate size: BPH may coexist with NGB
- See neurologic exam

Laboratory
- Evaluate for sacral abnormalities:
  - Sacral dimple, skin tag, discoloration or tuft of hair may suggest occult spinal dysraphism
- Sacral agenesis
- Focused neurologic exam:
  - Sacral root
  - Perianal sensation
- Anal tone, sphincter control

Imaging
- Imaging is most important in patients with risk factors for upper tract compromise:
  - DSD (especially males who void reflexively)
  - Impaired bladder compliance
  - Renal ultrasound (US): To screen for calculus, hydronephrosis, or mass
  - Excretory urography:
    - Delayed excretion of contrast with high urinary storage pressures
    - Hydronephrosis
    - Marked elevation of intravesical pressure or calculi

Focused neurologic exam:
- Evaluate for sacral abnormalities:
  - Sacral agenesis
  - Sacral dimple, skin tag, discoloration or tuft of hair

Digital rectal exam:
- Prostate size: BPH may coexist with NGB
- See neurologic exam

Urodynamics (UDS): Necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction.

Neurogenic DO (DSD):
- Loss of CNS inhibition

Diagnosis Procedures/Surgery
- Diagnostics and procedures necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction.

Neurogenic DO (DSD):
- Loss of CNS inhibition

Diagnosis Procedures/Surgery
- Urodynamics (UDS): Necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction.

Neurogenic DO (DSD):
- Loss of CNS inhibition

Diagnosis Procedures/Surgery
- Urodynamics (UDS): Necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction.

Neurogenic DO (DSD):
- Loss of CNS inhibition
Pathologic Findings
Bladder wall thickening with fibrosis and trabeculation

DIFFERENTIAL DIAGNOSIS
- Idiopathic overactive bladder
- Dysfunctional voiding

TREATMENT
GENERAL MEASURES (2)
- UDS is essential to determine lower urinary tract function/dysfunction and to plan urologic management.
- Maintaining low intravesical pressure protects upper urinary tracts
- Urinary drainage: Intermittent catheterization or external collection appliance
- Indwelling catheterization: Associated with recurrent UTIs, urethral erosion, and voiding dysfunction
- Interim self-catheterization: Most effective treatment; requires low storage pressure
- Surgical intervention is indicated when other therapies fail to protect the upper urinary tract or provide continence.

MEDICATION First Line
- Anticholinergics aimed at decreasing urinary storage pressure and reducing NDO. Most common side effects include dry mouth and constipation
  - Neostigmine 4–8 mg OD
  - Procyclidine extended release 0.375 mg BID
  - Oxybutynin 5 mg BID-TID
  - Oxybutynin transdermal patch 3.9 mg/day
  - Oxybutynin, topical gel 10% apply 1 sachet QD to dry area
  - Solifenacin 1–5 mg BID
  - Tolterodine LA 1.2 mg BID
  - Trospium CR 60 mg/day
  - f3 antagonist: Most common side effects include an increase in blood pressure and palpitations
- Adrenergic blockers: Decrease internal sphincter resistance, lower voiding pressure, ineffective for OAB
  - Alfuzosin 10 mg/day
  - Doxazosin start 1 mg/day to max 8 mg
  - Silodosin 8 mg/day
  - Terazosin start 0.4 mg to max 0.8 mg/day
  - Tamsulosin start 0.4 mg to max 0.8 mg/day
- α2 Agonist: Most common side effects include an increase in blood pressure and palpitations
  - Mirabegron 25 mg/day increase to 50 mg/day after 3-wk PRN

Second Line
- Botulinum toxin type A (onabotulinumtoxinA) injection into the external sphincter for OAB
  - Short-leaf, requires repeat injections
- Botulinum toxin injection into the detrusor for NDO
  - Duration of action is 3–9 mo
  - Requires repeated injections

SURGERY/OTHER PROCEDURES
- Endoscopic sphincterotomy or stenting
  - Only makes with UDS; requires condom catheter
- Augmentation cystoplasty using an intestinal segment to enlarge the bladder
  - Goal is to increase bladder volume and decrease bladder pressure
- Interstitial cystitis: Consideration for urinary drainage
- Limited dietary mandates: construction of a continent catheterizable stoma for the urinary reservoir, especially in females
- Revesicoectomy
  - Useful for those unable to perform self-catheterization (ie, quadriplegia)
- Cybertherapy with continent urinary reservoir
  - Neol or colost pouch, continent catheterizable stoma (appendix or tapered ileum)
- Cyproheptadine with ileal conduit

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
Neuromodulation, sacral nerve stimulation and posterior tibial nerve stimulation are not FDA-approved for the treatment of NDO but may have some benefit.

Complementary & Alternative Therapies
Acupuncture has been reported to improve symptoms of neurogenic bladder.

ONGOING CARE
PROGNOSIS
Proper urologic management greatly improves quality of life in patients with NGB dysfunction.

COMPlications
- Recurrent UTS
- Urinary retention
- Hydroceles
- Neoplastic transformation: Associated with chronic catheter
- Urethral erosion

FOLLOW-UP
Patient Monitoring
- Annual evaluation in high-risk patients may include UDS
  - EUS:
  - Imaging: Typically renal US
  - Serum creatinine

CODES
ICD9
- 596.3 Hyper trophy of bladder
- 596.54 Neurogenic bladder NOS
- 596.59 Other functional disorder of bladder

ICD10
- N31.8 Other neuro muscular dysfunction of bladder
- N31.9 Neuro muscular dysfunction of bladder, unspecified
- N32.81 Overactive bladder

CLINICAL/SURGICAL PEARLS
- Adequate management of lower urinary tract function is essential to avoid upper urinary tract compromise and preservation of renal function.
**NOCTURIA**

Garjoe D. Lavien, MD
Michael J. Naslund, MD

### BASICS

**DESCRIPTION**
- Nocturia is a symptom describing an individual who awakens at night one or more times to void. Each void is preceded and followed by sleep.
- Can negatively impact quality of life.
- Can be associated with depression, daytime fatigue, and increased orthopedic morbidity among the elderly.

**PATHOPHYSIOLOGY**

- **Risk Factors (1)**
  - **Prevalence**
    - Higher prevalence in men among young adults
    - Higher prevalence in men than women among elderly population groups
  - **Epidemiology**
    - The incidence of nocturia and total number of voiding episodes increases with age
  - **Obesity**
  - **Depression**
  - **Psychogenic polydipsia**
  - **Diabetes mellitus**
  - **Bladder outlet obstruction**
  - **Nephrogenic polyuria**

**ASSOCIATED CONDITIONS**

- **Obstructive: BPH, urethral stricture**
- **Psychogenic polyuria**

### DIAGNOSIS

**HISTORY**

- **Number of times getting up at night to urinate from time of going to bed until time of waking in the morning**
- **Degree of bother assessment**
- **Differentiate between awakening due to the urge to void vs. awakening due to other sleep disturbances**
- **Fluid intake habits**
- **Timing, volume**
- **Caffeine and alcohol consumption**
- **Previous pelvic surgery or radiation**
- **Daytime fatigue and depression**
- **Review of medications known to contribute to nocturia: such as diuretics, excessive calcium supplementation, antidepressants, or lithium.**
- **Swelling of lower extremities**

**PHYSICAL EXAM**

- Global or local neurologic deficits
- Digital rectal: Assess tone, prostate exam in men
- Pelvic exam in women: Anterior prolapse causing retention, urethral diverticulum, atrophic vaginitis causing irritative urinary symptoms
- Lung auscultation for rales, crackles
- Dependent edema, pedal edema
- Suprapubic distension consistent with urinary retention
- Obesity and a wide neck circumference raises the possibility of sleep apnea

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- Uricalysis: Low specific gravity (polyuria), RBCs (rule out stones, bladder cancer, foreign body, etc.), granulocyturia (nephrotic syndrome), glycosuria (diabetes mellitus), pyuria (UTI)
- Urine culture: UTI
- Urine osmolality: Dilute low values suggest inappropriate excretion of ADH or excess intake of water
- PSA if indicated
- Serum electrolytes: Hyperkalemia with impaired contractility

**Imaging**

- Bladder US with PVR volume for suspected urinary retention, especially if considering antimuscarinics
- Renal US may demonstrate hydronephrosis in cases of urinary retention or poorly compliant bladders
Diagnostic Procedures/Surgery

• Voiding diary:
  – All voiding episodes and volumes should be recorded for a 24-hr period; the time the patient actually goes to sleep and wakes for the day should also be noted.
  – Nocturnal urine volume (NUV) is the total volume of urine voided during the night (the first morning void is included in this sum since it represents urine excreted during sleep hours).
  – Nocturnal polyuria index (NPI): NPI divided by the total volume voided over the 24-hr period.
  – NPI >33% = nocturnal polyuria.
  – Nocturnal Bladder Capacity Index (NBC):
    – NBC = NPI/Maximum volume per void–1
    – NBC >1.0 suggests that the nocturnal bladder capacity cannot store the amount of urine made at night.
  – Urodynamic:
    – Helpful when empiric treatment for overactive bladder (OAB) or bladder outlet obstruction has failed to improve nocturia.
  – Urodynamic and sleep studies: Differentiate between sleep disorder and true nocturia.

Pathologic Findings

Nocturnal polyuria may be caused by several conditions including: 

1. Polydipsia
2. Hypercalcemia
3. Drugs, autonomic dysfunction

A voiding diary is extremely helpful to determine the cause of nocturia.

DIFFERENTIAL DIAGNOSIS

• Sleep disorders:
  – Most patients awaken due to the sleep disturbance, but recall this as an awakening to void.
  – May need polysomnography

• Urodynamics:
  – Bladder outlet obstruction, OAB, incomplete bladder emptying.
  – Neuropathic:
    – Neurogenic: idiopathic nocturnal polyuria, diabetes mellitus, central diabetes insipidus, nephrogenic diabetes insipidus, primary polydipsia, hypereosinophilia, drugs, autonomic failure, obstructive sleep-apnea.

TREATMENT

GENERAL MEASURES

• Nocturnal polyuria secondary to diabetics:
  – Change to afternoon dosing to induce an early evening diuresis rather than a nocturnal diuresis.
  – Treatment of underlying condition associated with nocturia.

MEDICATION

First Line

• Antimuscarinics are appropriate for reduced voided volumes.
  – Men only (α-blocker alone or combined with a 5α-reductase inhibitor likely modulated benefit) (C2A).

Second Line

• DDAVP for nocturia associated with nocturnal polyuria (IIb)– Dosing 0.01 mg PO, titrate up to 0.04 mg.
  – DDAVP has a high risk of hyponatremia.
  – Greatest risk seen in men >65 yr old.

SURGERY/OTHER PROCEDURES

Sacral neuromodulation for nocturia secondary to reduced voided volumes is associated with refractory daytime frequency and urgency (IIIb).

ADDITIONAL TREATMENT

• Radiation Therapy
  – N/A

• Additional Therapies
  – Behavioral training:
    – Pelvic floor muscle exercises, scheduled fluid feedback:
      – More effective than both drug therapy and placebo in treatment of nocturia associated with daytime urgency and urge incontinence (C5A) and CRP for obstructive sleep-apnea.

• Complementary & Alternative Therapies
  – None

ONGOING CARE

PROGNOSIS

Although it is often difficult to completely eliminate episodes of nocturia, characterizing nocturia according to cause-specific etiologies allows for cause-specific treatment.

COMPLICATIONS

• Traumatic falling accidents, including hip fractures, falling from sleep to urine.

• Urinary retention secondary to antimuscarinics

FOLLOW-UP

• Patient Monitoring
  – Bladder sonography with PVR as needed.
  – Repeat 24-hr voiding diaries.
  – Urinary retention secondary to antimuscarinics.

• Patient Resources
  – Medline Plus: Excessive Urination at Night

CODES

ICD9

• 596.59 Other functional disorder of bladder

ICD10

• N32.9 Neurohumoral dysfunction of bladder unspecified

• R35.1 Nocturia

• R35.8 Other polyuria

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)

• Bladder Outlet Obstruction
• Diabetes Mellitus
• Incontinence, Adult Female
• Incontinence, Adult Male
• Neurogenic Bladder
• Nocturia Algorithm
• Nocturnal Polyuria
• Overactive Bladder
• Urgency, Urinary (Frequency and Urgency)
• Urinary Retention
• Urodynamic Syndrome

• Emptying Diaries (see Section VII: Reference Tables)

CLINICAL/SURGICAL PEARLS

• The etiology of nocturia is not prostate or bladder related in the majority of men. Poor sleep pattern and fluid consumption/mobilization need to be considered.

• A voiding diary is extremely helpful to determine the cause of nocturia.
RISK FACTORS

- Prevalence
  - Incidence: 4 out of 5 cases occur in prepubertal males (<10 years old) prior to widespread use of MMR vaccine
  - Recent increase in incidence in postpubertal males corresponding to mumps outbreaks following national shortages of MMR vaccine as well as controversy related to MMR vaccine itself

- Immunocompromised states
- Bacterial orchitis even more rare and usually associated with concurrent epididymitis

- Prevalence
  - ~20% postpubertal males with mumps develop orchitis
  - Recent case reports of postpubertal mumps vaccinated males with mumps developing orchitis in outbreaks

PATHOPHYSIOLOGY

- Most commonly caused by hematogenous spread of mumps virus directly attacking testicular tissue resulting in parenchymal edema, congestion of seminiferous tubules, and perivascular infiltration of lymphocytes
- Rare case reports of other viruses causing orchitis (mononucleosis, coxsackievirus, others)
- Cases of bacterial orchitis usually result from local spread from the ipsilateral epididymis
- Truly noninfectious orchitis is usually idiopathic, trauma-related, or possibly autoimmune
- Orchitis is unilateral in 70% of cases
- Contrast-enhanced CT scan is indicated when there is clinical concern for a mass lesion

- ASSOCIATED CONDITIONS
  - Mumps
  - Epididymitis
  - STD in sexually active men
  - History of recent scrotal trauma
  - History of intravesical BCG therapy, may result in granulomatous orchitis

- GENERAL PREVENTION
  - Vaccination against mumps virus limits mumps orchitis
  - Protection from STD
  - Treatment of epididymitis prior to progression to epididymo-orchitis

- DIAGNOSIS

- HISTORY
  - Testicular pain and swelling
    - Mumps discomfort to severe pain
    - Onset of testicular pain and edema is acute
    - History of recent mumps infection
    - Systemic symptoms
      - Fever
      - Malaise
      - Myalgias
      - Nausea, vomiting
      - Headache
      - Obtain vaccination history

- Laboratory Tests
  - Mumps: serum immunofluorescence antibody assay
  - Urethral cultures if concern for urethritis
  - Urinalysis and urine culture
  - Evidence or history of immunocompromise
  - History of BPH
  - Evidence of past history of intravesical BCG therapy

- Imaging
  - Transrectal color Doppler ultrasonography
  - CT scan of pelvis

- DIAGNOSTIC TESTS & INTERPRETATION

- Lab
  - Uricalysis and urine culture
  - Urethral cultures if concern for urethritis
  - Mumps: serum immunofluorescence antibody assay

- Imaging
  - Transrectal color Doppler ultrasound is considered required by many clinicians:
    - Can rule out testicular torsion or malignancy
    - Additional imaging is unnecessary (i.e., CT scan or MRI)

- Diagnostic Procedures/Surgery
  - Usually not necessary

- Pathologic Findings
  - With viral infection, destruction of germ cells, edema and extensive inflammatory cell infiltrate is noted
  - Later seminiferous tubules can experience necrosis from increased pressure and edema, with subsequent interstitial fibrosis.
Differential Diagnosis
- Epididymitis
- Granulomatous orchitis, infectious and noninfectious
- Reactive hydrocele
- Sclerotic plaque
- Testicular malakoplakia
- Testicular torsion
- Torsion of testicular appendage
- Testicular tumor

Treatment

General Measures
- Supportive in nature
  - Bed rest
  - Hot or cold packs for analgesia
    - Applied for 10–15 min q 4 h or until pain subsides
  - Scrotal elevation and support with tight-fitting underwear or athletic support
  - Nonsteroidal anti-inflammatory drugs (NSAID)
  - Antimicrobics
  - Counsel patient on safe sex practices if STD suspected

Medication

First Line
- There are no targeted medications indicated in the treatment of viral orchitis. Supportive care is essential
- Bacterial orchitis requires coverage with appropriate antibiotic for suspected pathogen(s)
  - 35 years old, or epididymo-orchitis secondary to UTI
  - Additional gram-negative coverage with a fluoroquinolone or trimethoprim-sulfamethoxazole (TMP-SMX)
  - Tailor antibiotic prescription to local resistance patterns of most common UTI pathogens

Second Line
- NSA

Surgery/Others Procedures
- Surgical intervention is generally not indicated in the treatment of acute or chronic orchitis
- Associated scrotal pain or symptomatic hydrocele may require surgery
- Orchidectomy for chronic orchitis refractory to supportive measures is an option, but patients must be counseled surgery may not alleviate pain
- Consider microsurgical denervation of cord for chronic refractory orchalgia following favorable response to percutaneous cord block
- Consider in-office epididymectomy

Additional Treatment

Radiation Therapy
- There is no role for radiation therapy in the treatment of orchitis

Additional Therapies
- Interferon-2b has been investigated in bilateral mumps orchitis, given that the mumps virus replicates with a virus-associated transcriptase

Complementary & Alternative Therapies
- Patient-specific referral for psychologic evaluation and support for chronic refractory orchitis

Ongoing Care

Prognosis
- Most cases of mumps orchitis are self-limited, resolving within 3–10 days
- With appropriate antibiotic coverage, most cases of bacterial orchitis resolve without complication

Complications
- Unilateral testicular atrophy in up to 60% with mumps orchitis
- Bilateral testicular atrophy in up to 60% with mumps orchitis
- Sterility is rarely a sequel of unilateral orchitis with history of orchitis

Follow-Up

Patient Monitoring
- Most patients can be safely monitored in an outpatient setting
- A patient with a STD as the cause of orchitis should be tested for other STDs including Human immune deficiency virus (HIV)

Patient Resources
- http://www.nysayhealth.org
- http://www.nysayhealth.org

Additional Reading

See Also (Topic, Algorithm, Media)
- Acute Scrotum
- Orchitis
  - Orchitis, Granulomatous
  - Orchitis, Testicular
  - Orchitis, Testicular, Adult
  - Orchitis, Testicular, Adolescent

Codes

ICD-9
- 604.90 Orchitis and epididymitis, unspecified
- 604.91 Orchitis and epididymitis in diseases classified elsewhere
- 604.99 Other orchitis, epididymitis, and epididymo-orchitis, without mention of abscess

ICD-10
- N45.1 Epididymitis
- N45.2 Orchitis
- N45.3 Epididymo-orchitis

Clinical/Surgical Pearls
- Most cases of orchitis are viral in nature and self-limited, other cases are bacterial and most commonly associated with epididymitis.
- Physical exam findings include testes, scrotal tenderness with associated erythema of the scrotum with or without fever.
- Testicular ultrasonography is important to rule out torsion and malignancy.
- Medical therapy for orchitis is largely supportive; antibiotic coverage should be targeted to cover STDs in the young and sexually active and UTIs in the elderly.
- The role for surgical management of orchitis is limited.
OSTEITIS PUBIS, UROLOGIC CONSIDERATIONS

Patrick T. Gomella, MD, MPH
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

Osteitis pubis is a painful sterile inflammatory condition affecting the pubic symphysis. It is most commonly seen in athletes.

First described with suprapubic surgery and remains a potential complication of pelvic procedures.

EPIDEMIOLOGY

Incidence

Overall incidence in nonathlete populations unknown.

0.16% in procedures using bone anchors.

Prevalence

Overall prevalence in nonathlete populations unknown.

RISK FACTORS

- Invasive pelvic procedures
  - Several urologic procedures implicated
    - Radical prostatectomy
    - Prostate cryotherapy
    - TRUS Bx of prostate
    - TURP
    - Retropubic urethropexy: Specifically, Marshall–Marchetti–Krantz procedure
    - Sling procedures
    - Pelvic radiation

- Trauma

- Rheumatic disorders

- Pregnancy/parturition

- Overuse syndrome in athletes

- Genetics

No known genetic predisposition.

PATHOPHYSIOLOGY

Symphysis pubis is a nonsynovial amphiarthrodial joint at the confluence of the two pubic bones, consisting of an intrapubic fibrocartilaginous disc between thin layers of hyaline cartilage.

- Etiology unknown but may be related to periosteal trauma.

ASSOCIATED CONDITIONS

- Ankylosing spondylitis

- Rheumatoid arthritis

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Inciting event such as a pelvic procedure or trauma
- Insidious onset of suprapubic pain
- Pain radiating to thigh adductors, lower abdomen, perineum
- Pain worse when walking or when rising from a seated position

PHYSICAL EXAM

- Point tenderness over pubic symphysis
- Waddling gait
- Low-grade fever
- Increased pain with coughing or Valsalva
- Painful hip abduction

DIAGNOSTIC TESTS & INTERPRETATION

ALERT

Must rule out osteomyelitis, especially in postoperative patients.

Lab

- Not generally required to make diagnosis

- May see moderate leukocytosis and an increased erythrocyte sedimentation rate (ESR), raised levels of acute phase proteins (fibrinogen, C-reactive protein), and increased ESR are more suggestive of osteomyelitis.

Imaging

- Pelvic radiograph
  - Typically normal in acute phase
  - Articular surface erosion, sclerosis, osteophyte formation

- Scintigraphy
  - Increased uptake around pubic symphysis

- Symphysogram of joint
  - Pain on injection of contrast diagnostic

- Magnetic resonance imaging (MRI) most sensitive and considered gold standard
  - Acute (<6 mo): Bone marrow edema, fluid in joint, periarticular edema
  - Chronic (>6 mo): Subchondral sclerosis, bony margin irregularities, osteophytes (3)

Diagnostic Procedures/Surgery

- Symphysogram of joint
  - Pain on injection of contrast diagnostic

- Generally replaced by MRI.

- Aerobic/anaerobic culture of joint aspirate to rule out infection if clinically indicated.

Pathologic Findings

Scientific changes in bone architecture and degeneration of hyaline cartilage with normal periosteum (3).

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis (the most critical)

- Neoplasia of pelvic rami

- Bony metastases

- Pubic osteolysis

- Sports hernia (athletic pubalgia, sportsman’s hernia)

- Adductor strain

- Muscle tears

- Avulsion injuries

- Stress fractures

- Tears of acetabular labrum

TREATMENT

GENERAL MEASURES

- Rest, heat, or ice

- Physical therapy to strengthen pelvic girdle can be considered.

MEDICATION

First Line

- Nonsteroidal anti-inflammatory
  - Ibuprofen 200–800 mg 2–4 ×/d (max dose 2.4 g/d)
  - Naproxen 250–500 mg 2 ×/d (max dose 1.5 g/d for limited time)

- Cyclooxygenase-2 (COX-2) inhibitor
  - Celecoxib 100–200 mg 1–2 ×/d
  - Use lowest effective dose for shortest duration possible.

Second Line

- Oral glucocorticoids such as prednisone if local glucocorticoid injections fail
  - Typical short course (ie, 60 mg for 5 days)

- Can use a taper dose.

266
OSTEITIS PUBIS, UROLOGIC CONSIDERATIONS

SURGERY/OTHER PROCEDURES
- Glucocorticoid injection in joint may be useful for cases refractory to rest and NSAIDs (4)
  - Any steroid preparation can be used based on provider preference
    - Include an adjuvant anesthetic
  - Various surgical techniques can be used for cases refractory to medical management
    - Curettage
    - Wedge resection
    - Wide resection
    - Arthrodesis
  - If bone anchors are in place, their removal may be necessary

ADDITIONAL TREATMENT
- Radiation Therapy
  - Has been attempted in the past with mixed results, but not recommended due to risk of neoplasia
- Additional Therapies
  - Cryotherapy, ultrasound therapy, laser therapy, and electric stimulation have been used with variable success in athletic osteitis pubis
    - No data on success of these modalities for nonathlete populations
  - Anticoagulant therapy with heparin has been suggested as a possible treatment in a postoperative setting with some minimal success

COMPLEMENTARY & ALTERNATIVE THERAPIES
- Physical therapy

ONGOING CARE

PROGNOSIS
- Typically a drawn out and variable clinical course
  - Symptoms can last several months to several years
  - Operative procedures may be needed in 5–10% of cases

COMPLICATIONS
- Wedge or wide resection of pubic symphysis—risk of posterior instability of pelvic girdle leading to damage to sacroiliac joints
- Arthrodesis—risk of nonunion or death of bone graft site requiring additional surgery

FOLLOW-UP
- Patient Monitoring
  - Follow-up depends on patient symptomatology and procedures obtained
- Patient Resources
  - N/A

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Suprapubic Pain, General Considerations
- Sports Hernia (Athletic Pubalgia, Sportsman’s Hernia)
- Osteitis Pubis Images

CODES
- ICD-9 733.5 Osteitis condensans
- ICD-10 M85.38 Osteitis condensans, other site

CLINICAL/SURGICAL PEARLS
- Osteitis pubis pain and osteomyelitis pain worse when walking or when rising from a seated position.
- Essential to rule out osteomyelitis as a more significant cause.
- Rarely osteitis pubis and osteomyelitis of the pubis can coexist.
- To distinguish between osteomyelitis and osteitis pubis, a biopsy and culture of the affected area are necessary.
- Suspect the condition in a urologic patient where the pubic symphysis has been involved in urologic surgical intervention such as bone anchors or sling procedures.
OVERACTIVE BLADDER (OAB)

Nima Baradaran, MD
Samuel Walker Nickles
Eric S. Rozen, MD, FACS

BASICS

DESCRIPTION
• OAB is defined as a symptom syndrome consisting of urinary urgency, with or without incontinence, usually with urinary frequency and nocturia in the absence of causative factors or other identified pathologic conditions causing such symptoms.
• Urinary urgency is the key symptom.

ALERT
• OAB is not synonymous with detrusor overactivity (DO, strictly a urodynamic term) and should be distinguished from bladder pain syndrome.

EPIDEMIOLOGY
Incidence
Overall: 10.2–17.4% in adult males and 7.7–31.3% in adult females.
• Prevalence
  ≈16% of men and women over 40 suffer from OAB; the prevalence increases to 31% and 42%, respectively in patients >75 yr. OAB is more common in females.

RISK FACTORS
• Neurourologic: Stroke, Parkinson disease, multiple sclerosis, spinal injury, etc.
• Neuroendocrine: Cauterian, insulin-dependent diabetes mellitus, female gender, Depression, Aging associated with estrogen deficiency, Overactive bladder, Arthritis, Increased BMI.

GENETICS
For OAB, a definite genetic link is not well established.

PATHOPHYSIOLOGY
• Not well established or understood.
• DO is found in some but not all patients with OAB.
• Urthelial: afferent and efferent innervation, connective tissue, smooth muscle, pharmacologic (receptors, neurotransmitters, peptides, etc.), hormones, and other factors may contribute to OAB in individual patients.
• Ultimately, OAB results from either an afferent mechanism (underlying urgency), or a neurogenic or myogenic source or a combination of these.

ASSOCIATED CONDITIONS
• Post-void dribble
• BS
• High caffeine intake
• Depression/anxiety
• OB
• Smoking
• ADHD
• Obesity

GENERAL PREVENTION
Currently there are no known preventative measures to reduce the potential for development of OAB.

DIAGNOSIS

HISTORY
• Duration of symptoms
• Quantitative assessment of urinary frequency, nocturia, and incontinence (pad use)
• Documentation of urgency
• Quantitation of daily fluid intake
• Aggravating factors (caffeine, stress, etc.)
• Presence of dysuria, hematuria
• Response to prior therapy

ALERT
• GU history including childhood voiding dysfunction, prior surgery (BPH, urothelial stricture, stricture, etc.)
• History should include assessment of the impact of the disorder on daily life (OQL-1 and ICIQ-1 for urinary incontinence and OAB-q (3) for men and women with OAB specifically).

Medical/surgical/urogyn history (especially if associated with the initial symptom onset):
• Prior pelvic surgery: Pelvis, hysterectomy, anti-incontinence surgery. History of radiation therapy, etc.
• Pregnancy especially vaginal delivery/episiotomy
• Urinary especially vaginal delivery/episiotomy
• BOW (frequency, urgency, dysuria)
• Bowel function: Constipation

Neurologic:
• Neurologic history or events (eg, CVA/TIA, MS, Parkinson disease, trauma, back surgery, etc.)
• Neurologic exam including perineal sensation, bulbocavernous reflex, anal wink, resting, and volitional sphincter tone, mental status/cognitive function
• Abdominal masses, bladder distention
• Medical comorbidities: Congestive heart failure (CHF), diabetes, obesity, wiuos sufficiency, BPH, sleep apnea, etc.
• Medications (diabetes, prescription, OTC)
• Menopausal status and hormonal replacement: Contributes to atrophic vaginitis/urethritis
• Use of tobacco, alcohol, fluid intake, caffeine, etc.

PHYSICAL EXAM
General exam:
• Abdominal masses, bladder distention
• Mental status/cognitive function
• Neurologic exam including perinatal sensation, anal wink, resting, and volitional sphincter tone, bulbocavernous reflex
• Kneeling deep tendon reflexes:Sacral nerve compromise/injury

Pelvic exam:
• Condition of vaginal mucosa: Atrophy (thinning, pallor), narrowing of introitus, inflammation
• Kegel/bulbocavernous (BC) reflex

Urinalysis, urine cultures:
• Urinalysis, urine cultures: Possible diabetes, Hematuria: Possible kidney/bladder pathology, Proteines: Kidney/Chronic disease, Cytology: Atypia, urothelial carcinoma

Urinary urgency is the key symptom. OAB is not synonymous with detrusor overactivity (DO, strictly a urodynamic term) and should be distinguished from bladder pain syndrome.

DIFFERENTIAL DIAGNOSIS

Bladder Outlet Obstruction
Bladder cancer/carcinoma in situ
Bladder outlet obstruction/prostatitis hypertrophy
Congenital heart failure
Dysmenorrheal/vaginal endometriosis
Dysuria
Interstitial cystitis/painful bladder syndrome
Pelvic pain syndrome
Medications
Neurogenic bladder
Pelvic organ prolapse
Nutritional deficiencies
Sexually transmitted infection
Stress incontinence
Urethral diverticulum
Urinary tract infection

DIAGNOSTIC TESTS & INTERPRETATION

Urinalysis, urine cultures:
• Urinalysis, urine cultures: Possible diabetes, Hematuria: Possible kidney/bladder pathology, Proteines: Kidney/Chronic disease, Cytology: Atypia, urothelial carcinoma
• Response to prior therapy

GU history including childhood voiding dysfunction, prior surgery (BPH, urothelial stricture, stricture, etc.)
• History should include assessment of the impact of the disorder on daily life (OQL-1 and ICIQ-1 for urinary incontinence and OAB-q (3) for men and women with OAB specifically).

Medical/surgical/urogyn history (especially if associated with the initial symptom onset):
• Prior pelvic surgery: Pelvis, hysterectomy, anti-incontinence surgery. History of radiation therapy, etc.
• Pregnancy especially vaginal delivery/episiotomy
• Urinary especially vaginal delivery/episiotomy
• BOW (frequency, urgency, dysuria)
• Bowel function: Constipation

Neurologic:
• Neurologic history or events (eg, CVA/TIA, MS, Parkinson disease, trauma, back surgery, etc.)
• Neurologic exam including perineal sensation, bulbocavernous reflex, anal wink, resting, and volitional sphincter tone, mental status/cognitive function
• Abdominal masses, bladder distention
• Medical comorbidities: Congestive heart failure (CHF), diabetes, obesity, wiuos sufficiency, BPH, sleep apnea, etc.
• Medications (diabetes, prescription, OTC)
• Menopausal status and hormonal replacement: Contributes to atrophic vaginitis/urethritis
• Use of tobacco, alcohol, fluid intake, caffeine, etc.

PHYSICAL EXAM
General exam:
• Abdominal masses, bladder distention
• Mental status/cognitive function
• Neurologic exam including perinatal sensation, anal wink, resting, and volitional sphincter tone, bulbocavernous reflex

Pelvic exam:
• Condition of vaginal mucosa: Atrophy (thinning, pallor), narrowing of introitus, inflammation
• Kegel/bulbocavernous (BC) reflex

Urinalysis, urine cultures:
• Urinalysis, urine cultures: Possible diabetes, Hematuria: Possible kidney/bladder pathology, Proteines: Kidney/Chronic disease, Cytology: Atypia, urothelial carcinoma

Urinary urgency is the key symptom. OAB is not synonymous with detrusor overactivity (DO, strictly a urodynamic term) and should be distinguished from bladder pain syndrome.
Ongoing Care

Patient Monitoring
Depending on treatment modality dose follow-up with urologist or primary care physician is necessary

Follow-Up

Prognosis

Varies according to severity of disorder and compliance of the patient
50–80% of patients respond to combination of behavioral modification, pelvic floor therapy, and pharmacotherapy

Complications

Antimuscarinic agents are contraindicated in narrow angle glaucoma and patients should be aware of side effects (dry mouth, constipation, etc.)

Augmentation cystoplasty may lead to metabolic abnormalities and short bowel syndrome.

SNS implant site complications include infection and pain.

Botulinum toxin is associated with UTI and urinary retention

Surgical/Other Procedures (4)

Augmentation enteropyeloplasty: Using a portion of GI tract to increase bladder capacity. Usually involves use of balloon

Auto-augmentation: Incision of detrusor muscle creating a pseudodiverticulum (most commonly performed in pediatric age group)

Urinary diversion such as Birkh bilateral ureteroileostomy, rarely needed

Clinical use of endoscopic bladder transection, bladder shaveotomy, or transurethral phenol injection is no longer recommended for nonneurogenic OAB

Additional Treatment

Radiation Therapy

Additional Therapies

- Non-OAB approved
  - Ergonomics for females (topical or oral)
  - Tricyclic antidepressants (imipramine, etc.)
  - For intractable OAB, options are appliances, catheters (urethral), and pads with careful attention to skin care

Complementary & Alternative Therapies

- Acupuncture
  - Cognitive therapy

References

5. 1 evidence.

ADDISONAL READING

2. Acupuncture

ADDITIONAL MEASURES

- Lifestyle modifications and bladder/pelvic floor training in conjunction with pharmacotherapy is 1st-line therapy and may mandate of treatment
- Behavioral therapy:
  - Dietary and lifestyle modifications (weight loss, reduce caffeine intake, EtOH, and nicotine cessation)
  - Bladder retraining (education, diaries, self-monitoring)
- Pelvic floor physiotherapy: To reestablish inhibitory control over bladder storage
- Pelvic floor exercises (Kegel)
- Adjunctive measures include biofeedback, electrical stimulation, vaginal weights/cream, magnetic therapy, etc.

Medication

First Line

- Antimuscarinics: Inhibits the effect of acetylcholine at postjuncional muscarinic receptors on detrusor muscle cells. All used to treat OAB and all have Level 1 evidence.
  - Tolftepine (1–2 mg)
  - Trospium ER (20 mg)
  - Darifenacin (7.5–15 mg)
  - Oxybutynin (8–10 mg; XL 5–30 mg; patch every weekly)
  - Methadone (4–8 mg)
- β-3-adrenergic agonist agent: Promotes detrusor muscle relaxation
  - Mirabegron (25–50 mg)

Second Line

- Urgent PC (PTNS): Tibial nerve stimulation
  - Repeat procedure every 4–12 mo
- Interstim (sacral neuromodulation); Implantation of sacral nerves: Modulates activities of bladder, sphincter, and pelvic floor muscles
- Intravesical botulinum toxin (onabotulinumtoxinA) injection
- Address both motor efferent innervation and sensory afferent nerves that contribute to OAB. It is a transient effect requiring periodic retreatment at intervals of 4–12 mo.
- Anticholinergic and /or α-antagonists
- Bladder retraining (education, diaries, self-monitoring)

Surgery/other procedures (4)

- Augmentation enteropyeloplasty: Using a portion of GI tract to increase bladder capacity. Usually involves use of balloon
- Auto-augmentation: Incision of detrusor muscle creating a pseudodiverticulum (most commonly performed in pediatric age group)
- Urinary diversion such as Birkh bilateral ureteroileostomy, rarely needed
- Clinical use of endoscopic bladder transection, bladder shaveotomy, or transurethral phenol injection is no longer recommended for nonneurogenic OAB

TREATMENT

General measures

- Lifestyle modifications and bladder/pelvic floor training in conjunction with pharmacotherapy is 1st-line therapy and may mandate of treatment
- Behavioral therapy:
  - Dietary and lifestyle modifications (weight loss, reduce caffeine intake, EtOH, and nicotine cessation)
  - Bladder retraining (education, diaries, self-monitoring)
- Pelvic floor physiotherapy: To reestablish inhibitory control over bladder storage
- Pelvic floor exercises (Kegel)
- Adjunctive measures include biofeedback, electrical stimulation, vaginal weights/cream, magnetic therapy, etc.

- Bladder retraining (education, diaries, self-monitoring)
PAPILLARY NECROSIS, RENAL
Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

PATHOPHYSIOLOGY
- The renal papilla normally exists in the state of hypoxia because of the blood flow in the vasa recta which can be affected further with conditions that reduce blood flow
- Perfusion compromise in diabetes mellitus
- Diminution in blood flow because of stenosing of blood cells (sickle cell disease)
- Infection that causes infarction of the interstitium can lead to compression of the medullary vasculature
- Analgesic use causes COX inhibition and decreased prostaglandin production. This leads to decreased vascular perfusion, vasoconstriction and can cause ischemic necrosis
- Some medications can cause direct interstitial cell necrosis and decrease in prostaglandin production
- The necrotic, soft tissue can cause unilateral or bilateral ureteral obstruction

ASSOCIATED CONDITIONS
- Analgesic abuse
- Diabetic mellitus
- Pyelonephritis
- Sickle cell disease
- Urinary tract obstruction

GENERAL PREVENTION
- Treatment of underlying disorders including diabetes or sickle disease
- Avoidance of analgesic use

DIAGNOSIS

HISTORY
- May present with hematuria or obstruction or flank pain (2)
- With infection, fever, chills, dysuria, frequency, urgency, flank pain, and renal colic can occur
- Rarely, bilateral ureteral obstruction with necrotic tissue can present as acute oliguric renal failure

PHYSICAL EXAM
- Costovertebral angle tenderness
- Fever

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and urine culture
- Proteinuria, glycosuria, and low urine-specific gravity
- Epithelial cells and casts may be present
- CBC may demonstrate leukocytosis
- Metabolic panel can demonstrate azotemia and elevated creatinine

Imaging
- CT has become the imaging modality of choice
  - Contrast images show:
    - Ring shadows in the medulla
    - Contrast filled defects
    - Retrograde pyelogram:
      - Useful in patients with azotemia, contrast sensitivity, or other situations where intravenous contrast is contraindicated
      - Findings may reveal a club-shaped calyx or a filling defect in the ureter

Diagnostic Procedures/Surgery
Patient presenting with hematuria needs a full urologic work-up even if papillary necrosis is confirmed.

Pathologic Findings
- The common features depressed areas of cortical atrophy (3)
- Papilla shows various stages of necrosis, dequamation, and sloughing
- Focal necrosis: Involves only the tip of the papilla
- Diffuse necrosis: The entire papilla and portions of the medulla are involved
- Microscopically, changes of papilla may be a patchy appearance or complete coagulative necrosis
- Glimmer are typically unchanged

DIFFERENTIAL DIAGNOSIS
- Acute tubular necrosis
- Neoplastic process
- Carcinoma of the ureter or bladder
- NSAID abuse and/or overuse
- Pyelonephritis
- Renal trauma
- TB
- Unilateral stone disease

DESCRIPTION
- Renal papillary necrosis is ischemic necrosis of the papillae and occasionally the medullary pyramids
- The clinical course may be acute and rapidly progressive or chronic
  - Acute forms are symptomatic and may present with pyrexia, pyelonephritis, and hematuria
  - Typically chronic forms are asymptomatic and discovered incidentally on radiographic studies

RISK FACTORS
- Acute presenting symptoms include hematuria, flank or abdominal pain, and fever and chills

EPIDEMIOLOGY
Incidence
Most cases occur after the 6th decade of life and papillary necrosis is uncommon in patients <40 yr
- Female > Male (1.1:1.0) [1]

Prevalence
N/A

ASSOCIATED CONDITIONS
- Diabetes mellitus
- Sickle cell trait or disease
- Pyelonephritis
- Urinary tract obstruction of any cause
- Antiretroviral treatment

GENETICS
N/A
PAPILLARY NECROSIS, RENAL

TREATMENT

GENERAL MEASURES
- Hydration, oral or intravenous
- Glycemic control, if diabetic
- Definition and treatment of sickle disease

MEDICATION

First Line
- Cessation of any associated/causative medications including analgesics
- Treatment of underlying cause of ischemia
- Broad-spectrum antibiotics, if associated with pyelonephritis

Second Line
N/A

SURGERY/OTHER PROCEDURES
- When a patient presents with acute urinary obstruction, drainage is indicated with percutaneous nephrostomy, ureteral stent placement, or endoscopic/ureteroscopic removal of obstructing sloughed tissue
- In the nonacute case, renal pelvic or ureteral filling defect can be electively evaluated with ureteroscopy
- Nephrectomy is rarely warranted

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Depends on the basis for the ischemia, the complicating factors, and the amount of necrosis

COMPLICATIONS
- Infection may develop in the desquamated necrotic papilla
- Calculi can develop on the base of the sloughed papilla
- Obstruction can develop along the ureter from multiple sloughed papillae

FOLLOW-UP

Patient Monitoring
- Monitoring includes the kidney itself for further necrosis and for changes in function
- Causes of ischemia should be closely monitored

Patient Resources
http://www.scripps.org/articles/1151-renal-papillary-necrosis

CLINICAL/SURGICAL PEARLS
- Gross hematuria in a patient with sickle cell disease suggests papillary necrosis.
PARATESTICULAR TUMORS
Mohamed T. Ismail, MD
Sallyanne M. Fisher, MSN, FNP-C, CUNP

BASICS

DESCRIPTION
- Intratesticular tumors involving the testicular tunic, epididymis, or cord structures. Can be benign (~70%) or malignant (~30%).
- The paratesticular region includes: contents of the spermatic cord, testicular tumors, epididymis, and vesicovaginal remnant (appendages testis and epididymis).
- 50% of extratesticular tumors are found within the spermatic cord.
- Of these, 10% are malignant.
- The majority represent benign lipomas.
- Mesenchymal tumors of the spermatic cord include rhabdomyosarcoma, leiomyosarcoma, liposarcoma, lipoma, fibrosarcoma, and myxochondrosarcoma.
- The most common paratesticular tumor in children is rhabdomyosarcoma, which accounts for ~24-40% of all paratesticular tumors.
- Adenomatoid tumor accounts for 30% of epididymis tumors and is a benign:
- Typically seen in 3rd and 4th decades of life.
- Rarely arises in testicular tunica or spermatic cord (1%).
- Leiomyosarcoma is the most common type of paratesticular sarcoma in adults:
- Incidence peaks in the 6th and 7th decades.
- Can be bilateral.
- May accompany a hydrocele or hernia.
- Cytoplasm is a benign tumor that involves the epididymis in young adults:
- Ven-Hill and Hill syndrome (2%)
- Typically bilateral.
- Malignant mesothelioma presents in older patients (55–75) and usually presents in association with a hydrocele.
- Malignant lymphoma: Cord structures are frequently invaded by testicular lymphoma, but primary lymphomas do occur rarely.
- Epidermoid cysts occur in up to 40% of men.
- 70% of these are true cysts and contain lymphatic fluid (1%).

EPIDEMIOLOGY

Incidence
- The exact incidence of paratesticular soft tissue neoplasms is difficult to estimate.
- Rhabdomyosarcoma:
- Occurs primarily in children and adolescents during the 1st 2 decades of life.
- Racial differential: White (3:1), Black (3:1)
- Leiomyosarcoma: Incidence varies, ~110 reported cases in the literature.

Prevalence
- Primary malignancies of the epididymis or paratesticular structures in adults are extremely rare.
- Rhabdomyosarcoma accounts for a large proportion of the paratesticular tumors in the pediatric population.

RISK FACTORS
- Marijuana and cocaine use in the parents is associated with rhabdomyosarcoma.
- Von-Hippel-Lindau syndrome is associated with epithelioid sarcomas.
- Equine semen is prone to scrotal injury with up to 77% evidence of scrotal pathology (1%).

GENETICS
- Partial monosomy of chromosome 11 often leads to embryonal rhabdomyosarcoma.
- Alveolar rhabdomyosarcoma is characterized by translocations t(2;13)(q35;q14) or t(1;13)(p36;q14); this subtype carries a poor prognosis.

PATHOPHYSIOLOGY
- Electron microscopy is very helpful in differentiating the type of sarcoma.
- Subtypes of sarcoma include rhabdomyosarcoma, leiomyosarcoma, liposarcoma, fibrosarcoma, malignant fibrous histiocytoma, and desmoplastic round cell tumor.
- Soft tissue sarcomas tend to infiltrate local tissues and are not limited to the testis.
- Delays in presentation due to embarrassment.
- Testicular vs. paratesticular:
- Solid vs. cystic (2%).
- Solid lesions almost always require exploration.
- Simple cystic lesions are mostly benign.
- Computed tomography (CT) of the abdomen and pelvis with and without contrast for staging.
- Paratesticular tumors may spread to retroperitoneal lymph nodes or hematogenously depending on the histology of the primary tumor.
- Chest radiograph.
- CT abdomen or pelvic metastases are seen.
- Clinical staging of retroperitoneal lymph nodes.
- Radioscopy bone scan.
- Especially for elevated alkaline phosphatase or symptoms with rhabdomyosarcoma.

DIAGNOSIS

HISTORY
- Patient complains of mass within his scrotum, distinct from the testicle:
- Typically painless.
- Delays in presentation due to embarrassment.
- Occult complete history to include accompanying symptoms, duration, and constitutional changes (2%).

PHYSICAL EXAM
- Palpation of the testes, epididymis, and cord structures bilaterally including the inguinal region:
- Rhabdomyosarcoma reveals a firm mass that is usually distinct from the testis.
- Adenomatoid tumor appears clinically as small solid lumps and is most commonly found at the head of the epididymis, testicular tunics, or spermatic cord.
- Cystadenoma presents as asymptomatic cystic lumps and are bilateral in up to 1/3 of cases.
- Leiomyosarcoma normally presents as a discrete nodular mass, frequently near the spermatic cord and entirely separate from the testicle.
- Liposarcoma usually presents in an older patient as a large fatty-applying mass.
- Lymphoma presents as a hard, tender mass, separate from the testis; seen in young adults.
- Electron microscopy suggests a fluid-filled lesion such as a hydrocele.
- Cervical exam of the groin is necessary to rule out hernia and to evaluate for lymphadenopathy.
- Masculine are occasionally accompanied by hydrocele.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Ultrasonography (midstream) and culture if epididymitis is suspected (1%).
- Tumor markers to include α-fetoprotein (AFP), or human chorionic gonadotropin (hCG), α-fetoprotein (AFP), or lactate dehydrogenase (LDH) should be sent if the origin of the tumor is in question.

Imaging
- Gold standard: Scrotal ultrasound (US)/CT (1%)
- To evaluate location and characteristics of the lesion within the scrotum.
- Testicular vs. paratesticular.
- Solid vs. cystic (2%).
- Solid lesions almost always require exploration.
- Simple cystic lesions are mostly benign.
- Computed tomography (CT) of the abdomen and pelvis with and without contrast for staging.
- Paratesticular tumors may spread to retroperitoneal lymph nodes or hematogenously depending on the histology of the primary tumor.
- Chest radiograph.
- CT abdomen or pelvic metastases are seen.
- Clinical staging of retroperitoneal lymph nodes.
- Radioscopy bone scan.
- Especially for elevated alkaline phosphatase or symptoms with rhabdomyosarcoma.

Diagnostic Procedures/Surgery
- Surgery is often diagnostic and therapeutic.

ALERT
- Pericapsular biopsies are contraindicated due to the documented risk of seeding in the scrotal wall with malignancy.
- Bone marrow aspirate:
- Routine part of staging at a time of diagnosis for rhabdomyosarcoma.

Pathologic Findings
- Electron microscopy can help differentiate between the different types of sarcomas; these differences can be quite subtle.
- Leiomyosarcoma spreads 1st by lymphatics, then hematogenously, and last by local extension.

DIFFERENTIAL DIAGNOSIS
- Adenomatoid tumors:
- Most common benign paratesticular tumor.
- Angiomylipoblastoma.
- Cystadenoma of the epididymis.
- Epithelioid cyst.
- Liposarcoma.
- Fibrous pseudotumor of testicular tunic.
- Rhabdomyosarcoma.
- Leiomyosarcoma.
- Lipoma of the spermatic cord.
- Leiomyosarcoma.
- Malignant fibrous histiocytoma.
- Mesotheloma, benign, testicular tunic.
- Mesotheloma, malignant, testicular vaginismus.
- Associated with asbestos exposure.
Surgery/Other Procedures

- Testicular or paratesticular lesions suspected to be malignant should be removed by radical inguinal orchietomy with high ligation of the spermatic cord.
- Early clamping of the cord limits hematogenous spread in leiomyosarcoma.
- Rhabdomyosarcoma: Consider hemiscrotectomy for any degree of scrotal wall involvement.
- The Intergroup rhabdomyosarcoma study group (IRSG) recommended radical inguinal orchietomy and routine RPLND in all males >10 yr and in boys <10 with metastasis noted on imaging.
- Complete surgical excision with a negative margin has significant impact on local recurrence and overall survival in soft tissue sarcomas.

Additional Treatment Radiation Therapy

- Rhabdomyosarcoma: -4,000-6,000 cGy of radiation (15 Gy) over 5 wk.
- Dose and port size determined by the tumor’s primary site, patient age, and tumor burden.

Additional Therapies

- Complementary & Alternative Therapies
- Radiation Therapy
- Chemotherapy for malignant rhabdomyosarcoma
- Vincristine, cyclophosphamide, and actinomycin D-based chemotherapy in patients with gross or microscopic residual disease
- Radical inguinal orchiectomy with high ligation of the spermatic cord for any degree of scrotal wall involvement.

Complications

- Disease associated death in ~10% of malignant cases.
- Treatment associated:
  - Metastasis and/or incomplete primary resection lead to poorer overall prognosis.
  - Adjuvant treatment via radiation is warranted.

Follow-up

- Serial US for equivocal lesions, especially in the epididymis.
- Biopsy is recommended for uncertain or indeterminate lesions.
- Surveillance after local recurrence.

- Additional Therapies
- Complementary & Alternative Therapies
- Radiation Therapy
- Chemotherapy for malignant rhabdomyosarcoma
- Vincristine, cyclophosphamide, and actinomycin D-based chemotherapy in patients with gross or microscopic residual disease
- Radical inguinal orchiectomy with high ligation of the spermatic cord for any degree of scrotal wall involvement.
- The Intergroup rhabdomyosarcoma study group (IRSG) recommended radical inguinal orchietomy and routine RPLND in all males >10 yr and in boys <10 with metastasis noted on imaging.
- Complete surgical excision with a negative margin has significant impact on local recurrence and overall survival in soft tissue sarcomas.

Codes

- ICD9: 171.9 Malignant neoplasm of other specified sites of male genital organs;
- 222.8 Benign neoplasm of other specified sites of male genital organs;
- 239.3 Neoplasm of unspecified nature of other genital organs.

- ICD10: C63.7 Malignant neoplasm of other specified male genital organs;
- D29.8 Benign neoplasm of other specified male genital organs;
- E44.5 Neoplasm of unspecified behavior of other genital organs.

Clinical/Surgical Pearls

- It is impossible to distinguish a benign from a malignant tumor based on physical exam.
- Can be indistinguishable from testicular masses.
- Penetrating biopsies contraindicated due to documented seeding in scrotal wall with malignancy.

PARKINSON DISEASE, UROLOGIC CONSIDERATIONS

Robert C. Flanigan, MD, FACS
Sam J. Brancato, MD

BASICS

DESCRIPTION
Parkinson disease (PD), also called paralysis agitans, is a neurodegenerative disorder associated with loss of dopaminergic neurons.

• Three cardinal features are rest tremor, rigidity, and bradykinesia.
• Postural instability, sometimes deemed a cardinal feature, is nonspecific and usually absent in early disease.
• Autonomic dysfunction is manifested by urinary urgency and frequency, constipation, and orthostatic hypotension. Retention can also be seen.

EPIDEMIOLOGY

Incidence
• PD incidence increases with age, from 17.4 cases per 100,000 persons per year between 50–59 yr of age to 93.1 in 100,000 persons per year between 70–79 yr of age.
• Life risk of developing PD is 1.5%.
• Voiding dysfunction occurs in 40–70% of patients with PD.

Prevalence
N/A

RISK FACTORS

• Men are about 1.5 times more likely than women to develop PD.
• The median age of onset is 65 yr and the mean duration of the disease from diagnosis to death is 15 yr.
• Young-onset PD affects 5–10% of patients with the initial symptom arising before the age of 50 yr.

Genetics

• About 10% of patients with PD have a 10-q degree relative with the disease, typically without a clear mode of inheritance.
• Mutations in two genes cause autosomal dominant forms of PD:
  – α-Synuclein gene (SNCA): Located on chromosome 4q (rarely prominent early in the course of PD) (constipation) and sexual dysfunction
  – Leucine-rich repeat kinase 2 (LRRK2): located on chromosome 12q (often prominent early in the course of PD).
• To date, approximately 16 risk loci have been known to contain disease-causing mutations.

PATHOPHYSIOLOGY (1)

• The net effect of the basal ganglia on micturition is inhibitory, which is abolished due to cell loss in the substantia nigra.
  – The bladder detrusor can thus become unstable and result in urgency and frequency with urge incontinence.
  – The smooth sphincter is synergic, however pseudosynergism, as well as delay in striated sphincter relaxation (bradykinesia) leading to urinary retention (2).
• PD can be also associated with bowel dysfunction (constipation) and sexual dysfunction.

• Urinary symptoms tend to become worse in the course of the disease. Early on other reversible causes such as benign prostatic enlargement in men can cause similar symptoms.
• Centrally acting anticholinergic drugs such as trihexyphenidyl and benztropine have been used to treat PD and can cause urinary retention.

ASSOCIATED CONDITIONS

• Dementia
• Depression
• Erectile dysfunction
• Sleep disturbance
• Autonomic dysfunction
• Parkinson disease

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

• Urinary symptoms usually appear after the onset of neurologic symptoms.
• Assess for LUTS:
  – Storage symptoms: Most common, include nocturia, urgency, frequency, and incontinence.
  – Voiding symptoms: Difficult initiating stream, weak FOS/prolonged urination, and straining.
• Elevated PVRs are uncommon in PD patients.
• Assess for concurrent urologic conditions:
  – BPH in men and SUI in women.
• Assess for polypharmacy:
  – Central acting anticholinergics listed below can be used in younger patients in whom tremor is the major symptom but may exacerbate incomplete emptying and urinary retention.
  – Benzhexol meylrate (Cogentin), trihexyphenidyl (Artane), biperiden (Akineton), orphenadrine (Norflex, Flexerin)

PHYSICAL EXAM

• Cardiac features are rest tremor, rigidity, and bradykinesia.
• Slow, pill-rolling tremor of the hands (4–6 cycles/s) seen primarily at rest.
• Abolished by use of the affected hand.
• Agitated by stress and cold weather.
• Facial expressions can be immobile or rigid and speech slowed.
• Slow, shuffling gait with loss of normal arm swing (usually prominent early in the course of PD).

• Assessment of pelvic floor reflexes, motor and sensory.
  – Dystonic postural tremor.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• No diagnostic test exists for PD as the diagnosis is clinical.
• Standard urologic evaluation (UA, CBC) based on initial symptoms.

Imaging

• Brain MRI is reserved for patients suspected of having PD who fail to respond to therapeutic doses of L-dopa administered to exclude rare secondary causes.
• Routine urologic imaging is not required.

Diagnostic Procedures/Surgery

• PD is a clinical diagnosis, although the definition of PD is a postmortem finding based on the neuropathologic examination.

Uradyaynics

• Deterioration overactivity is the most common symptom.
• Sphincteric instability in the striated sphincter during involuntary bladder contraction is common, however, this does not cause obstruction.
• Pseudodysuria may occur, as well as delay in striated sphincter (bradykinesia) relaxation at the onset of voluntary micturition, both of which can be misinterpreted as true dyskinesia.
• Detrusor voiding relatively rare in PD and when present it is often be due to anticholinergic medications.

• Detrusor is a useful tool for investigating concomitant obstruction secondary to BPH.
Pathologic Findings

Irrespective Lewy bodies and Lewy neurites are the pathologic hallmarks of PD.

Differential Diagnosis

- Parkinson
  - Multiple system atrophy
  - Normal aging
  - Vascular parkinsonism (multiple infarcts within the basal ganglia and subcortical white matter)
  - Parkinson plus syndromes
  - Voiding dysfunction

General Measures

- For urologic symptoms of frequency, urgency, and incontinence, clinicians should offer behavioral therapies (eg, fluid management, clean intermittent catheterization) as 1st-line therapy.
- Evaluate medications that may result in urinary symptoms (such as retention/obstruction) with anticholinergic drugs such as trihexyphenidyl and benztropine used to treat some patients with PD.
- Assess for elevated PVRs, specifically if taking anticholinergics.
- Anticholinergic drugs such as trihexyphenidyl and benztropine may contribute to cognitive decline.
- Urinary incontinence due to detrusor overactivity may decrease urinary symptoms

Medication

First Line

- For urologic symptoms of frequency, urgency, and incontinence, anticholinergics are commonly used but should be monitored closely in elderly as they may contribute to cognitive decline.
  - oxybutynin 5 mg PO TID
  - Tolterodine 4 mg PO daily
  - Others (solifenacin, fesoterodine, darifenacin, trospium)

- β-3-Adrenergic agonist agent: Promotes detrusor muscle relaxation and can also be considered for obstructive bladder symptoms
  - Mirabegron (25–50 mg)

Second Line

- β-3-Adrenergic agonist agent: Promotes detrusor muscle relaxation and can also be considered for obstructive bladder symptoms
  - While not specifically approved for PD, is approved for treatment of urinary incontinence
  - Tolterodine LA 4 mg PO BID
  - Selective serotonin-norepinephrine reuptake inhibitors (SSNRI's): Duloxetine 20–40 mg PO BID
  - Selective serotonin reuptake inhibitors (SSRI's): Citalopram 20 mg PO BID
  - Tricyclic antidepressants (TCA): Imipramine 10–25 mg PO BID–TID

Surgery/Other Procedures

- Bladder outlet obstruction found on urodynamic testing

Additional Therapies

- Incontinence aids may be necessary and are primarily chosen by the degree of abscessing required and the ease of use. During the night, high absorbency pads are usually required.

Complementary & Alternative Therapies

- Dietary fiber, laxatives, and prokinetic drugs (such as serotonergic agonists) are used to treat PD-related bowel dysfunction.
- Ongoing Care

Prognosis

- PD is a progressive neurodegenerative disorder.
- Despite a variable disease course, the overall prognosis is poor with a mean duration of the disease from diagnosis to death of 15 y.

Complications

- Urinary incontinence
- Urinary retention

Follow-Up

- Assess for elevated PVRs, specifically if taking anticholinergics

Patient Monitoring

- Assess for elevated PVRs, specifically if taking anticholinergics

Patient Resources

- Urinary incontinence is a common feature of PD due to symptoms of obstructive bladder.
PELVIC ORGAN PROLAPSE (CYSTOCELE AND ENTEROCELE)

W. Stuart Reynolds, MD, MPH
Roger R. Dmochowski, MD, MMHC, FACS

BASICS

DESCRIPTION

Pelvic organ prolapse (POP): The descent of one or more of the anterior vaginal wall, posterior vaginal wall, uterosacral, or area of vagina (bilateral vault or cuff after hysterectomy)

Cystocele: Anatomic defect of the anterior vaginal wall in which bladder prolapses into the vagina

Enterocoele: Anatomic defect of the vaginal apex typically, small rectovaginal prolapse into the vagina

Rectocoele: Anatomic defect of the posterior vagina; the rectum prolapses into the vagina

Defects in any or many vaginal compartments (anterior, posterior, apex) may occur together

PREVALENCE

- 2% of US women report symptoms of vaginal bulging
- 40% of US women have POP on exam
- Women have an 11% lifetime risk of undergoing surgery for POP and/or UI by age 80

ASSOCIATED CONDITIONS

- Pelvic strain (high impact activity or work)
- Menopause
- Obesity
- Parity
- Race/ethnicity (Hispanic > White > African American)

RISK FACTORS

- Age
- Racemiethnicity (Hispanic > White > African American)
- Parity
- Obesity
- Menopause
- Prior POP surgery
- Menopause
- Pelvic strain (high impact activity or work)

GENETICS

- Inherited familial risk (sisters and mothers)
- 2-3 times more common if positive family history for POP
- Inherited collagen disorders (eg, Ehlers–Danlos syndrome)
- Genome-wide studies ongoing with several potential candidate genes identified, most related to elastic and collagen metabolism (eg, LAMC-1)

PATHOPHYSIOLOGY

- Integrated mander to the bony pelvic through the endopelvic fascial structure, suspensory ligaments, levator ani muscles, and pelvic organs help maintain the pelvic organs in the proper anatomic position in the pelvis.
- Classically, three levels of vaginal support are described:
  - Level I: Uterosacral and cardinal ligaments support upper 1/2 of vagina, cervix, and uterus.
  - Level II: Pubocervical and rectovaginal fascia attach laterally to the arcus tendineus fascia pelvis to support midportion of vagina
  - Level III: Direct attachment of vagina to urethra, perineal body, and levator ani muscles

DIAGNOSIS

HISTORY

- Assess for prolapse symptoms
  - Vaginal bulging, including visualization or palpation of a "bulge" in the vagina
  - Pelvic pressure, heaviness, or dragging sensation
  - Vaginal mucosal irritation, bleeding, discharge, and/or infection
- Provocative maneuvers (cough and Valsalva) to demonstrate urethral leakage; repeated with defecation
- Low backache, temporally associated with POP
- Splinting/digitation: Applying manual pressure to vagina or rectum to assist with voiding or defecation
- Vaginal mucosal irritation, bleeding, discharge, and/or infection
- Vaginal bulging, including visualization or palpation of a "bulge" in the vagina
- Vaginal pressure, heaviness, or dragging sensation
- Vaginal mucosal irritation, bleeding, discharge, and/or infection
- Abnormal examination findings:
  - Estrogen alone in postmenopausal with after menopause

PHYSICAL EXAM

- Useful to employ POP staging
  - POP quantification system (POPS)
    - Stage II: The prolapse is demonstrated
      - Stage I: Most distal portion of the prolapse is >1 cm above the level of the hymen
      - Stage II: Most distal portion of the prolapse is ≤1 cm below the hymen
    - Stage III: Complete eversion of the total length of the lower genital tract is demonstrated
  - Assessment of urinary incontinence
    - Provocative maneuvers (cough and Valsalva) to demonstrate urethral leakage, repeated with prolapse reduced to detect occult SUI

DIFFERENTIAL DIAGNOSIS

- Urethral diverticulum
- Cystocele
- Enterocele
- Rectocele
- Soft tissue vaginal mass
- Urinary incontinence

LAB

- Urinalysis and urine culture, as indicated

DIAGNOSTIC TESTS & INTERPRETATION

- Urethral function tests (leak point pressure, urethral pressure profilometry) assess urethral function and degree of SUI, if any

IMAGING

- Routine imaging is not indicated; imaging may supplement exam with complex cases
- Differentials:
  - Assess defecatory dysfunction, including degree of rectocele and rectal emptying
  - Voiding cystourethrogram
  - Urodynamic testing

- Allows dynamic assessment of pelvic organs and bladder volume
- Magnetic resonance imaging (MRI)
  - Allows dynamic imaging of functional relationships among the pelvic floor viscera and supporting structures, and assess pelvic pathology
- Expensive; clinical utility over exam alone not established

PATHOPHYSIOLOGY

- Relationships among the pelvic floor viscera and supporting structures
- Allows dynamic assessment of pelvic organs and bladder volume
- Magnetic resonance imaging (MRI)
  - Allows dynamic imaging of functional relationships among the pelvic floor viscera and supporting structures, and assess pelvic pathology
- Expensive; clinical utility over exam alone not established

TREATMENT

- General measures
  - Management is generally surgical
  - Bowel regimen for constipation
  - Hormone replacement, typical vaginal, for atrophic vaginitis
  - Estrogen alone in postmenopausal with after hysterectomy: estrogen and progesterone if uterus present, even if postmenopausal

MEDICATION

- First Line
- Second Line

276
**SURGERY/OTHER PROCEDURES**

**Additional Therapies**

**Radiation Therapy**

- Concomitant anti-incontinence procedure
  - Anterior colporrhaphy and paravaginal repair
  - Vaginal pessary: Supportive and space-occupying
- Vaginal apex fixation to the presacral fascia at S3–S4 using biologic or synthetic material
  - Transvaginal approach
  - Abdominal approach
- Colpocleisis
  - Partial colpocleisis (De La Fort colpocleisis)
- Uterosacral ligament fixation
  - Vaginal intercourse

- Mesh material complications occur in 10% of women;
- Requires routine maintenance and care (removal, cleaning, vaginal inspection)
- Synthetic mesh materials, if used in POP surgery, if anti-incontinence procedure not performed
- Perioperative complications of bleeding, pelvic organ injury, bladder dysfunction, infection
- Postoperative complications include vaginal and pelvic pain, vaginal shortening or narrowing, dyspareunia

**CLINICAL/SURGICAL PEARLS**

- Complete assessment of all vaginal compartments and symptoms, best with supervision of a physical therapist
- Requires routine maintenance and care (removal, cleaning, vaginal inspection)

**ADDITIONAL READING**

**CODES**

- ICD9: 618.6 Vaginal enterocele, congenital or acquired
- ICD10: N81.5 Vaginal enterocele

**REFERENCES**

2. Diwadker GB, Barber MD, Feiner B, et al. Prophylactic, synthetic MUS at time of vaginal POP surgery reduces need for additional surgery in women at 12 mo (OR 0.48, 95% CI 0.21–0.77 [46A])
3. Urethrocele
**PELVIC PAIN, FEMALE**
Kai-Wen Chuang, MD
Robert M. Moldwin, MD, FACS

**DIAGNOSIS**

**HISTORY**
- History of present illness
  - Urinary or rectal symptoms
  - Pain with defecation
  - Pain with bladder distension
  - Menstrual history
  - Past medical history
  - Family history

**PHYSICAL EXAM**
- Vital signs
- Head and neck exam
- Cardiovascular exam
- Respiratory exam
- Abdominal exam
- Pelvic exam
- Rectal exam
- Vaginal exam

**DIAGNOSTIC TESTS & INTERPRETATION**

**IMAGING**
- Ultrasound
- CT scan
- MRI
- Nuclear medicine
- Radiation therapy

**Pathologic Findings**
Based on diagnosis

**DIFFERENTIAL DIAGNOSIS**
- Gynecologic: Acute or chronic pelvic pain
- Urinary: UTI, bladder stones
- Gastrointestinal: Diverticulitis, appendicitis
- Musculoskeletal: Pelvic fracture, sacroiliac joint pain

**GENERAL PREVENTION**
- Prevent infection
- Safe sex practices

**RISK FACTORS**
- Prior pelvic inflammatory disease (PID)
- Prior sexually transmitted infections (STIs)
- Substance dependence
- Personal history of abuse
- Depression, anxiety

**GENETICS**
- Twin studies and familial clustering do suggest a genetic basis for increased nociception
- No established inheritance pattern

**PATHOPHYSIOLOGY**
- Exact mechanism unknown
- Complex and multifactorial, combining, biologic, psychological, and social factors

**ASSOCIATED CONDITIONS**
- Endometriosis, pelvic inflammatory, ovarian cysts, adhesions
- Urinary tract infections (UTIs), STIs, and PID
- Irritable bowel syndrome (IBS)
- Interstitial cystitis (IC)

**BASICS**
- Chronic pelvic pain (CPP) is defined as discomfort below the umbilicus lasting ≥6 mo
- Etiology often unknown and symptom severity often out of proportion to objective findings
- Bears impact on physical, mental, emotional, and sexual well-being

**Epidemiology**
- Prevalence: 1 in 7 women
- No established inheritance pattern
- Twin studies and familial clustering do suggest an increased risk

**Risk Factors**
- Substance dependence
- Personal history of abuse
- Depression, anxiety

**Etiology**
- Complex and multifactorial, combining, biologic, psychological, and social factors
- Exact mechanism unknown
Chronic Pelvic Pain Syndrome (CPP) In Females

**ON-GOING CARE**

**PROGNOSIS**

Variable and dependent on underlying etiology and treatment modalities.

**COMPICATIONS**

- Risk of pharmacologic dependence, tolerance, and abuse associated with long-term angesic therapy.
- Surgical complications such as bleeding and infections are procedure specific.

**FOLLOW-UP**

- Patient Monitoring
  - CPP is typically managed in outpatient setting.
  - Monitor serum hepatic/renal function and electrocardiogram when using antidepresants.

**Patient Resources**

- The International Pelvic Pain Society
  - www.pelvicpain.org

**REFERENCES**

**ADDITIONAL READING**

- See Also (Topic, Algorithm, Media)

- Chronic Pelvic Pain Syndrome (CPP) In Females

- Inflammatory Bowel Disease (Ulcerative Colitis and Crohn Disease), Urologic Considerations

- Neurological啪CTitis (ICP/Plaflate Bladder Syndrome)

- Prostatect, Chronic, Nodular. Inflammatory and Noninflammatory (NI-CP/CPS III A and B)

**CODES**

- ICD9 - 338.29 Other chronic pain
- ICD10 - 617.8 Endometriosis, site unspecified
- ICD10 - 625.9 Unspecified symptom associated with female genital organs

**CLINICAL/SURGICAL PEARLS**

- The pathophysiology of CPP is multifactorial, and the treatment for it is multidisciplinary.
- Initial evaluation for CPP aims to identify Ne- or organ-threatening conditions and rule out anatomic or structural abnormalities.
- Subsequent management of CPP focuses on symptom control and consistent care.
- Treatment may take time, and cure may not be possible. Therefore, it is important to set patient-centered yet realistic goals of care.

PENILE PROSTHESIS PROBLEMS (INFECTION/EXTRUSION/MALFUNCTION)
Nelson Bennett Jr., MD

BASICS
DESCRIPTION

r While generally very reliable, penile prostesis can
become infected, undergo extrusion and suffer form
mechanical failure.
r 2 types of penile prosthesis, malleable (semirigid,
noninflatable, nonhydraulic) and inflatable.
Inflatables consist of 2-piece (pump and cylinders)
and 3-piece (pump, cylinders, and reservoir).
r Implanted via suprapubic or penoscrotal approach.
r Meticulous sterility is required.
r Infections of any or all parts of the device
components require removal of the entire device.
r Extrusion/erosion of the device may occur into or
through the urethra, penile glans, proximal crura,
bladder or bowel, or adjacent vascular structures.
r Mechanical breakdown may manifest as inability to
inflate/deflate device, abnormal erectile morphology,
or auto inflation.

EPIDEMIOLOGY
Incidence
N/A

Prevalence

r Overall infection rate: 1–8%
r Prosthesis revision infection rate: 10–13%
r Prosthesis revision through infected field infection
rate: 18%
r Mechanical failure rate 2-piece: 5% @ 5 yr
r Mechanical failure rate 3-piece: 18% @ 15 yr

RISK FACTORS

r Infection: Diabetes, spinal cord injury, previous
penile prosthesis, immunocompromised state, h/o
UTI, obesity
r Extrusion/erosion: Previous surgery, previous pelvic
radiation, penile fibrosis, aggressive dilation, lack of
surgical experience, Peyronie disease, previous
penile prosthesis, upsizing of cylinders
r Mechanical failure: Inadequate dilation of reservoir
space

Genetics
N/A

PATHOPHYSIOLOGY

r Infection
– 1–8% this percentage increases with number of
revision surgeries
– Most common bacteria – Staphylococcus
epidermidis
– Other bacteria: MRSA, Pseudomonas,
Enterococcus, Prevotella, Morganella
– Gram-negative bacteria may be associated with
rapid infection
– Biofilm plays important role in bacterial adherence
and infection
r Extrusion/erosion
– Erosion through skin is inherently infected
– Pre-existing infection may hasten erosion
– Iatrogenic-facilitated erosion may result from
overaggressive dilation

280

r Malfunction
– Mechanical failure rates are 15% at 5 yr and 30%
at 10 yr
– Common reasons include aneurysm, tubing
breakage, reservoir leakage, and connector failure
– Auto inflation is usually due to improperly
positioned reservoir

HISTORY

ASSOCIATED CONDITIONS

PHYSICAL EXAM

r Conditions associated with erectile dysfunction
– Adrenal disorders
– AIDS-associated neuropathy
– Alzheimer’s
– Cardiac arterial disease
– CNS infections
– CNS tumors
– Diabetes mellitus (Type I and II)
– History of kidney or liver transplant
– History of myocardial infarction
– History of prostatectomy, cystectomy, or colectomy
– Hyperprolactinemia
– Hypertension
– Hyperthyroidism
– Hypogonadism
– Hypothyroidism
– Liver failure
– Multiple sclerosis
– Peripheral vascular disease
– Renal failure

GENERAL PREVENTION

r The preoperative assessment should include issues
such as the patients’ needs and expectations of the
device (1,2)
– Issues such as complications and the irreversibility
of the procedure should be exhaustively discussed
and documented through informed consent
r Infection
– Ensure UTI or infectious skin rash is absent
– Tight control of serum glucose and HbA1C
– Preoperative parenteral antibiotic of vancomycin
+ aminoglycoside or imipenem
– Meticulous adherence to sterile technique
– Limit OR traffic
– 10-min scrub of operative area
– 10-min scrub for OR staff
– Use of alcohol-based solution for final prep
– Avoid having prosthesis contact skin
– Use antibiotic-coated/antibiotic dripped
prosthesis (3)
◦ Postoperative oral antibiotics 7–10 days
postoperatively
r Extrusion/erosion
– Avoid aggressive corporal dilation
– Avoid upsizing of cylinders
– Avoid early/premature inflation of device
r Malfunction
– Place corporotomy closing sutures before device
insertion to avoid iatrogenic puncture
– Demonstrate proper function and placement of
the device prior to conclusion of surgery

DIAGNOSIS
Assess for fever, chills, pain, lethargy, fatigue, change
in bowel or bladder function, dysuria, frequency,
urethral discharge.
r Assess penis/scrotum for erythema, edema,
induration, pain in palpation of penis/scrotum,
presence of wound drainage, adherence of
prosthesis components to skin.
r Erosion/extrusion of device through glans, urethral
meatus, scrotal skin, or perineum.
r Assess functionality of device by
inflation/deflation—if suboptimally rigid or deflated
pump, consider fluid leak.
r Assess penile contour/morphology upon inflation:
– Buckling of cylinder or S-shaped deformity
suggests oversizing of cylinders.
– Floppy glans (SST deformity) suggests undersized
cylinders or inadequate corporal dilation.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
r Urinalysis
r Urine culture and sensitivity
r CBC with differential
r Metabolic profile
r Erythrocyte sedimentation rate

Imaging

r Usually not necessary
r Ultrasound scrotum—may reveal abscess
r MRI (with device inflated)—useful in assessment of
corporal abnormalities.

Diagnostic Procedures/Surgery
Cystourethroscopy may reveal urethral erosion of
cylinders or erosion of device component into bladder.

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS

r Intraoperative complications (4)
– During corporal body dilation: Urethral
perforation, cross over perforation of opposite
crura during dilation
– Reservoir position: Bladder perforation or
improper positioning during the implant procedure
– Component failure: Check device function before
implantation; careful technique to avoid cylinder
injury during corporal body closure
r Postoperative complications:
– Infection
– Erosion (oversized cylinder): Often associated with
pain and buckling
– Undersized cylinder (“concorde deformity” or
“floppy glans”) whereby there is excess mobility
of the glans
– Cylinder aneurysm
– Fluid leak
– Auto inflation/inability to deflate or inflate


TREATMENT
GENERAL MEASURES
- Broad-spectrum antibiotic should be started if infection is suspected.
- If sepsis is present, resuscitation is indicated prior to explanation of prosthesis.

MEDICATION
First Line
- AUA guidelines recommend the following antibiotic prophylaxis at the time of implantation (See Additional Reading):
  - Ampicillin/Tranxactin (or aztreonam with renal insufficiency) plus
  - 1st/2nd generation cephalosporin or vancomycin
- Alternative regimens include:
  - Ampicillin/Tranxactin
  - Tranxactin/Clavulanate
  - Piperacillin/Tazobactam

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Infection
  - Removal of prosthesis may be completed on a semiurgent basis (within 24 hr)
  - Immediate prosthesis salvage (replacement) may be possible in absence of frank pusulence, erosion, necrotic tissue, poorly controlled diabetes, immunosuppression
  - Mucosal protocol for prosthesis salvage (6):
    - 1. Antibiotic solution (1 g vancomycin and 80 mg gentamicin in 1 L of normal saline)
    - 2. 1/2 strength hydrogen peroxide
    - 3. 1/2 strength betadine
    - 4. Pressure washing with 1 g vancomycin and 80 mg gentamicin in 1 L of normal saline
    - 5. 1/2 strength betadine
    - 6. 1/2 strength hydrogen peroxide
    - 7. Antibiotic solution
    - 8. Change instruments, gowns, drapes, and gloves immediately before prosthesis insertion
  - Extrusion/erosion
    - Prolonged extrusion/erosion managed by affixing RTS to the interior, proximal corpora with permanent suture
    - Alternatively, placing a purse-string suture in the corpora at tubule exit site
  - Delayed extrusion/erosion (periathal) is best managed by immediately removing offending cylinder and prolonged Foley drainage. If contralateral cylinder has been placed, it may remain in place
  - Malfunction
    - Floppy glans
      - Perform corporeoplasty to reposition glans or dilate distal corpora
    - Fluid leak
      - Replace device
    - Autinflation
      - Reposition, incise fibrotic capsule, or replace reservoir

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

ONGOING CARE
PROGNOSIS
- Prosthesis satisfaction rates approach 95% for patients and partners
- Satisfaction rates for revision surgery is ~40%
- Infection rates have decreased with antibiotic coated or antibiotic-dipped prosthetics

COMPLICATIONS
- Revision surgery may result in infection, extrusion/erosion, or malfunction
- Delay replacement of device may result in corporal fibrosis

FOLLOW-UP
Patient Monitoring
- In case of revision surgery, prolonged antibiotic treatment may be required
- Biweekly follow-up is indicated until patient is cleared to use the device

Patient Resources

CODES
ICD9
- 996.39 Other mechanical complication of genitourinary device, implant, and graft
- 996.69 Infection and inflammatory reaction due to other internal prosthetic device, implant, and graft
- 996.76 Other complications due to genitourinary device, implant, and graft

ICD10
- T83.40XA Infection/infest d/f pt prosth-dev in genit ltr, init
- T83.6XXA Infect/inflm react d/t prosth dev/grft in genitrct, init
- T83.89XA Other specified complication of genitourinary prosthetic devices, implants and grafts, initial encounter
- T83.424A Displacement of penile (implanted) prosthesis, initial encounter

CLINICAL/SURGICAL PEARLS
- Metabolic stability is required during the implant in the operating room.
- Infections of any or all parts of the device components require removal of the entire device.
- Extrusion/erosion of the device may occur into or through the urethra, penile glans, proximal crus, bladder or bowel, or adjacent vascular structures.
- Mechanical breakdown may manifest as inability to inflate/prolong device, abnormal erectile morphology, or auto inflation.

PENILE PROSTHESIS PROBLEMS (INFECTION/EXTRUSION/MALFUNCTION)
PATHOPHYSIOLOGY
E-cadherin (16q22) immunoreactivity correlates with Viral genes E6 & E7 expressed on high-risk HPV, Prevalence Incidence
- In 2014 in the United States, the American Cancer Society estimates that about 1,640 new cases of penile cancer will be diagnosed and 325 will die of penile cancer
- In the United States:
  - Hispanics (8.6 per million)
  - Blacks (4.0 per million)
  - White (3.8 per million)
Prevalence
- Race in developed countries
- Most common genitourinary malignancy in Uganda
  - In Brazil 6–14/100,000 males (1)
  - Whites (3.9 per million)
  - Blacks (4.0 per million)
  - In the United States
  - 1st line is surgical excision of lesion on penis.
  - Zoon balanitis
  - Ulcer from STD
  - Seborrheic keratosis
  - Lichen sclerosis
  - Bowenoid papulosis (multiple flat, warty lesions, BXO
  - Erythroplasia of Queyrat; shiny red patches on skin of the penis typically penile shaft)
DIAGNOSTIC TESTS & INTERPRETATION
LAB
- CBC, urinalysis, urine culture
PHYSICAL EXAM
- Persistent induration, erythema, nodularity of propude and/or glans. Usually has been treated with several agents, lesions
- Growth or sore on the penis that doesn’t heal within 4 wk
- Patients often denies or ignores lesions and present at later stages
- Bleeding ulcer
- Penile pain—infected
  - New onset of priapism with a mass suggests metastatic corporeal body lesion (eg, melanoma)
DIAGNOSIS
HISTORY
- Persistent irritation, erythema, nodularity of propude and/or glans.
  - Bleeding ulcer
  - Food smell with purulence
  - Phimosis
  - Inflamed adenopathy
ASSOCIATED CONDITIONS
- Phimosis
- Balanitis
- Sexually transmitted infections (STIs/STDs)
GENERAL PREVENTION
- Good hygiene, avoid smear accumulation
- Newborn circumcision more protective than circumcision later in life
- HPV vaccines may reduce the risk of HPV and, consequently, penile cancer (unproven)
ALERT
- Presentation at advanced stage is not uncommon due to denial and poor hygiene.
Diagnosis
- SCCs are graded using the Broders System:
  - Grade IV: Cells deeply invasive, marked nuclear atypia, increased mitotic activity, dermal keratin pearls
  - Grade III: Cells deeply invasive, marked nuclear pleomorphism, nuclear mitoses, necrosis, lymphatic and perineural invasion, no keratin pearls
DIFFERENTIAL DIAGNOSIS
- BKD
  - Erythroplasia of Queyrat: shiny red patches on mucosal surfaces (glans and prepuce if uncircumcised)
  - Bowen disease (red, scaly patches on the keratinized skin of the penis typically penile shaft)
  - Bowenoid papulosis (multiple flat, warty lesions, sometimes pigmented)
  - Condyloma acuminsata: increased risk of nodal metastases
  - Giant condylomata
  - Epidermodysplasia Verruciformis disease: Adenocarcinoma of the penis
  - Accumulation of pigmented keratinous material: perianal disease
  - Acrodermatitis enteropathica
  - Condyloma lata: lichen sclerosis
  - Bowenoid papulosis
  - Seborrheic keratosis
  - Ulcer from STD
  - Zoon balanitis
Pathologic Findings
- Most malignancies involve the epithelial surface of the penis.
  - CIS (erythroplasia of Queyrat, Bowen disease of the penis, low-grade papillomas)
  - Viral genes E6 & E7 expressed on high-risk HPV
  - Viral genes E6 & E7 expressed on high-risk HPV
  - HPV types 16, 18, and 33 or HIV
  - Presence of foreskin and/or phimosis
  - Invasive cancer:
    - 95% are SCCs
    - Torres of invasive atypical keratinoepithelium with multiple mitosis inside the lamina propria or deeper. Sites with foci of aberrant and atypical keratinization called squamous pearls
    - SCCs are graded using the Broders System:
      - Grade I: Well-differentiated, keratin pearls, prominent papillar bridges
      - Grade II: Greater nuclear atypia, increased mitotic activity, dermal keratin pearls
      - Grade III: Cells deeply invasive, marked nuclear pleomorphism, nuclear mitoses, necrosis, lymphatic and perineural invasion, no keratin pearls
  - Simply malignant involve the epithelial surface of the penis.
  - CIS (erythroplasia of Queyrat, Bowen disease of the penis, low-grade papillomas)
  - Presence of foreskin and/or phimosis
  - HPV types 16, 18, and 33 or HIV
  - Presence of foreskin and/or phimosis
  - Invasive cancer:
    - 95% are SCCs
    - Torres of invasive atypical keratinoepithelium with multiple mitosis inside the lamina propria or deeper. Sites with foci of aberrant and atypical keratinization called squamous pearls
    - SCCs are graded using the Broders System:
      - Grade I: Well-differentiated, keratin pearls, prominent papillar bridges
      - Grade II: Greater nuclear atypia, increased mitotic activity, dermal keratin pearls
      - Grade III: Cells deeply invasive, marked nuclear pleomorphism, nuclear mitoses, necrosis, lymphatic and perineural invasion, no keratin pearls
DIFFERENTIAL DIAGNOSIS
- BKD
  - Bowen disease (red, scaly patches on the keratinized skin of the penis typically penile shaft)
  - Bowenoid papulosis (multiple flat, warty lesions, sometimes pigmented)
  - Condyloma acuminsata: increased risk of nodal metastases
  - Giant condylomata
  - Epidermodysplasia Verruciformis disease: Adenocarcinoma of the penis
  - Accumulation of pigmented keratinous material: perianal disease
  - Acrodermatitis enteropathica
  - Condyloma lata: lichen sclerosis
  - Bowenoid papulosis
  - Seborrheic keratosis
  - Ulcer from STD
  - Zoon balanitis
GENERAL MEASURES
- 1st line is surgical excision of lesion on penis.
- Wound care issues are paramount after excision of the primary and after inguinal node dissections.
Grossly should be taken to minimize the complications of penile deformity and/or mental stress after excision the primary and diligent attention to avoiding infection, hematoma, and lymphocele after inguinal node dissection is necessary.
- Treatment based on extent of disease and specific tumor type. Recommendations below are for invasive SCC (B). For other tumor types, see specific sections.
**PROGNOSIS**

- Depends on T-stage and nodal status
- ARCC staging:
  - Stage I: Cancer is moderately or well-differentiated and only affects the subepithelial connective tissue
  - Stage II: Cancer is poorly differentiated, affects lymphatics, or invades the corpus or urethra
  - Stage III: Deep invasion into the penis and metastasis into one lymph node
  - Stage IV: The cancer has invaded into structures adjacent to the penis, metastasized to pelvic nodes, or distant metastasis is present

- 5-yr overall survival for men with node-negative disease is 80–90%.
- 5-yr survival for N+ is max 30–40%.
- Married or previously married men have better prognosis
- African Americans tend to present with more advanced disease and have a poorer prognosis

**COMPLICATIONS**

- Infections
  - Erosion of lymphadenopathy into femoral artery
  - After radiation or brachytherapy urethral fistula, erosion of lymphadenopathy into femoral artery
- Infections
  - Radical penectomy may be required

**FOLLOW-UP**

- Patient Monitoring
  - Close inspection for local recurrence usually every 3 mo for 5 yr
  - Consider imaging for ambiguous findings on physical exam

**Patient Resources**

**CLINICAL/SURGICAL PEARLS**

- A painless lesion on the penis is the most common presentation.
- 40% of cases of penile cancer in the United States derive from HPV infections.
- 2-cm surgical margin is critical for a successful partial penectomy.
- Historically 6 wk of antibiotics are required to appropriate assessment of inguinal region adenopathy, consideration can also be given to early fine-needle biopsy.

---

**ICD9**

- 187.2 Malignant neoplasm of glans penis
- 187.3 Malignant neoplasm of body of penis
- 187.4 Malignant neoplasm of penis, part unspecified

**ICD10**

- C60.9 Malignant neoplasm of penis, unspecified
- C60.2 Malignant neoplasm of glans penis
- C60.9 Malignant neoplasm of penis, unspecified
retinoblastoma (RB) tumor suppressor proteins through interactions with tumor protein 53 (p53) and HPV contributes to the development of penile cancer.

**Genetics**
- HPV contributes to the development of penile cancer through interactions with tumor protein 53 (p53) and retinoblastoma (RB) tumor suppressor proteins.

**Pathophysiology**
- Inguinal LNs serve at the primary lymphatic drainage for the penis, scrotum, urethra, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower extremities, and lower extremities.
- Inguinal LNs lie within the femoral triangle (inguinal ligament, sartorius, and adductor longus) and are separated into superficial and deep groups by the fascia lata of thigh.

**ASSOCIATED CONDITIONS**
- Balanitis
- Phimosis
- STDs

**DIAGNOSIS**

**History**
- Circumcision
- PHIS: infection
- Penile condylomata
- Genital warts
- Sexual History (multiple partners, early age of initial intercourse)
- Smoking History
- Viral warts
- Laser treatment
- Treatment with topical and ultraviolet A phototherapy.

**Imaging**
- No imaging studies are currently utilized extensively for staging.
- Ultrasound and PET-CT can be used to detect recurrences.
- Chest x-ray and CT abdomen/pelvis can be used for follow-up.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- No tissue parameters, including HPV and p53 status, are predictive of LN involvement.

**TREATMENT**

**General Considerations**
- Pelvic LNs are palpable in 60% of presenting patients.
- Pelvic nodes should only be offered in experienced centers.
- Palpable inguinal nodes are predictive of LN involvement.
- Palpable inguinal nodes are present in 60% of presenting patients.

**DIAGNOSIS**

**Histology**
- If FNAC is positive, bilateral inguinal and pelvic LAD should involve at least 8 LNs, as this improves long-term survival.
- If contralateral frozen section is positive, deep inguinal or pelvic LAD and chemotherapy is warranted.
- If FNAC is negative, no resolution with antibiotics, excisional biopsy or inguinal LAD.
- If contralateral frozen section is negative, surveillance.
- If pelvic LNs are palpable, inguinal and pelvic LAD and contralateral superficial or modified inguinal LAD.
- T3-T4 primary tumors should undergo bilateral superficial inguinal or OSN.
- If FNAC is positive, bilateral inguinal and pelvic LAD and contralateral superficial or modified inguinal LAD.
- If contralateral frozen section is negative, surveillance.

**DIFFERENTIAL DIAGNOSIS**
- Reactive LN: Syphilis, herpes, chancroid, lymphogranuloma venereum, genital herpes disease
- Malignant diseases: Metastatic melanoma, lymphoma
- Systemic diseases: HIV, leprosy, human immunodeficiency virus, cytomegalovirus

**TREATMENT**

**GENERAL MEASURES**

**MALIGNANT DISEASES**
- HPV infection
- Phimosis
- Circumcision
- HPV vaccination may reduce risk (unproven)

**REACTIVE CONDITIONS**
- Autoimmune diseases: Sarcoidosis, lupus
- Systemic diseases: Mononucleosis, rubella, human immunodeficiency virus, cytomegalovirus

**ASSOCIATED CONDITIONS**
- Prepubertal circumcision is protective against penile cancer.
MEDICATION

First Line

- Antibiotics
  - Use of antibiotics has become controversial for enlarged LNs.
  - Historically, a 4-6 wk course of antibiotics such as a cephalosporin or augmentin was recommended to rule out infection in Tis and Ta tumors with palpable LNs.
  - Delay in LAD, a potentially curative treatment, has brought the use of antibiotics into question
  - FNAC can help determine if LNs are due to metastasis or infection

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical LAD (2,3)
  - Superior margin: Superior margin of the external ring to the anterior superior iliac spine (ASIS)
  - Inferior margin: 20 cm inferior from the ASIS to 15 cm inferior from the pubic tubercle
- Modified LAD (after Carstons)
  - Includes area lateral to the femoral artery and caudal to the fossa ovalis
  - Preservation of the saphenous vein
  - No transection of the sartorius muscles
- Conversion to radical LAD if there are positive LNs
- Endoscopic LAD (4)
- Radical LAD (2,3)
- Complete radical LAD can be performed through 3 endoscopic ports
- Nerve plexus is equivalent to open surgery
- Decreased complications
- The viability of the skin flaps developed during an inguinal LN dissection is based on the anastomotic vessels within the superficial fat layer of Campers fascia which course lateral to medial along the skin lines. This is a key anatomic dissection plane as the lymphatic drainage of the penis lies beneath Campers fascia allowing this superficial fatty layer to remain attached to the skin flaps during a groin dissection
- When performing an inguinal LN dissection for a clinically negative groin, a modified technique should be used to decrease morbidity. The key components of this technique include the following:
  - Shorter incision (~10 cm), preservation of the saphenous vein, minimizing dissection lateral to the femoral artery, and avoiding transection of the Sartorius muscle

ADDITIONAL TREATMENT

Radiation Therapy

- Adjuvant radiation therapy may improve 3-year LND survival in patients with extensive metastases and/or extranodal disease
  - Side effects include edema and pain
- Radiotherapy in clinical N0 patients is not recommended

Additional Therapies

- Adjunct chemotherapy
  - 3 courses of cisplatin and 5-fluorouracil for pN2–3
  - No adjuvant chemotherapy for pN0

COMPETITIVE COMPLEMENTARY & ALTERNATIVE THERAPIES

None are effective

ONGOING CARE

PROGNOSIS

- 5-yr cancer-specific survivals:
  - 70–80% in pN0 disease
  - 70–40% in pN1 disease
  - <30% in patients with positive pelvic LNs
- Predictors of cancer-specific survival: Pathologic stage of LNs, vascular and/or lymphatic involvement, primary tumor thickness

COMPLICATIONS

- LAD complications:
  - Wound infection
  - Skin necrosis
  - Wound dehiscence
  - Thigh numbness
  - Lymphedema
  - Lymphorrhea
  - Sartorial swelling
  - Suprapubic swelling
  - Pulmonary embolism

FOLLOW-UP

Patient Monitoring

- Recurrences occur most often within 2 yr after inguinal LAD
- Nomograms available
- Evaluation should include an exam and ultrasound-guided FNAC
- Maximum follow-up length of 5 yr
- Surveillance (patient did not have LAD)
- FNAC can help determine if LNs are due to metastasis or infection
- 30% in pN2–pN3 disease
- 90–100% in pN0 disease
- 30–70% in pN1 disease

Follow-up

- Every 6 mo for yr 1 and 2
- Every 6 mo for yr 3, 4, and 5
- Every 3 mo for yr 3, 4, and 5
- Every 6 mo for yr 4, 5, and 6

CLINICAL/SURGICAL PEARLS

- Penile cancer metastasizes to regional LNs before distant disease
- Treatment is dependent on the clinical presence of LNs, tumor stage, and tumor grade.
- Inguinal LAD is potentially curative and can improve long-term outcomes in penile cancer with nodal involvement.
- Careful tissue management, antibiotics, suction drains, and compression stockings can minimize the morbidity associated with LAD.

ADDITIONAL READING

ICD9

- 187.4 Malignant neoplasm of penis, part unspecified
- 196.5 Secondary and unspecified malignant neoplasm of lymph nodes of inguinal region and lower limb
- 196.6 Enlargement of lymph nodes

ICD10

- C60.9 Malignant neoplasm of penis, unspecified
- C77.4 Sec and unspecified malignant neoplasm of inguinal and lower limb nodes
- R59.0 Localized enlarged lymph nodes

CLINICAL/SURGICAL PEARLS

Penile cancer metastasizes to regional LNs before disseminating systemically.
- Treatment is dependent on the clinical presence of LNs, tumor stage, and tumor grade.
- Inguinal LAD is potentially curative and can improve long-term outcomes in penile cancer with nodal involvement.
- Careful tissue management, antibiotics, suction drains, and compression stockings can minimize the morbidity associated with LAD.

REFERENCEs

PATHOPHYSIOLOGY

In general, 5% of men have evidence of PD.

Prevalence

Incidence

EPIDEMIOLOGY

DESCRIPTION

In the setting of erectile trauma, an altered cell-mediated immunity and anti-elastin antibodies support an immunologic component.

Autoimmune components have been demonstrated in 38–75% of men with PD.

The result is hypertrophic microvascular hemorrhage and inflammation in the tunica albuginea, which may calcify, preventing uniform expansion of the corpora cavernosa during erection.

– Congenital chordee may present as penile curvature. If severe, it can cause dyspareunia.

– Can be a result of complications of penile prosthesis implantation.

– Congenital chordee may present as penile curvature in infants due to a deficiency in formation of the urethra or the Buck fascia ventrally.

– Leporionic chordee secondary to circumcision or other penile skin procedures.

BASICS

In general, 5% of men have evidence of PD.

RISK FACTORS

– Buckling erectile trauma

– Fracture of the tunica albuginea during sexual activity

– Intra cavernous injection of vasoactive agents

– Pharmacologic injection to assess cavernous arterial function, presence of venoocclusive dysfunction, and degree of erectile curvature, lateral indentation or circumferential wasting.

– Nipple self-photography of erect penis using instant (Polaroid) or digital film imaging is useful to classify the extent of the curvature.

– Urethroscopy for urethral pathology

Pathologic Findings

– PD is characterized by a fibrous noncompliant plaque within the tunica albuginea, which may calcify, preventing uniform expansion of the corpora cavernosa during erection.

– Microscopy: A fibrous noncompliant plaque demonstrates nonparallel arrangement of collagen fibers and disordered arrangement of elastin fibers in PD.

DIFERENTIAL DIAGNOSIS

– Balanitis, balanoposthitis, paraphimosis

– Cellulitis

– Chordee

– Congenital penile curvature

– Epididymitis

– Erectile dysfunction

– Fourier gangrene

– Hypospadias

– Idiopathic urethralgia

– Insect bite

– Leukemic infiltration of the penile shaft

– Nipple pain syndrome

– Penile prosthesis problem: 5-shaped or sigmoid curvature with buckling of prosthetic cylinders that are too long; pain also suggests infected prosthesis components

– Priapism

– Psychiatric causes of pain

– Pubic neuralgia

– Referred pain, GI (rectum, hemorrhoids, fistula, fissures)

– Referred pain, GU (prostatitis, urethritis, proctitis, retention, urethral, urethral calculus)

– Reflected syndrome

– STD (herpes, chancre)

– Torn frenulum

– Trauma (ESW, penile fracture)

– Urethral foreign bodies

– Urethral stricture following urethroplasty

– Urethral stricture

DIAGNOSIS

HISTORY

– It is critical to differentiate penile pain from urethral pain. History of voiding symptoms and/or recurrent UTIs.

– Establish duration, degree, and location of curvature and pain

– Dyspareunia

– Painful erection (suggests PD)

– Dysuria

– Establish duration, degree, and location of curvature and pain

– History of penile prosthesis

– History of priapism

– History of penile tumor

– History of penile prosthesis

– History of penile trauma

– History of penile prosthesis

– History of penile trauma

– History of penile surgery as a child

– History of penile trauma

– History of penile prosthesis

– Palpable nodule

– Painful ejaculation

– Dyspareunia

– Usually not useful unless for workup of infections

– Usually useful

– Urinary symptoms and/or recurrent UTIs

– Urethroscopy for urethral pathology

– Urethral stricture

– Urethral foreign bodies

– Urethral stricture following urethroplasty

– Urethral stricture

ASSOCIATED CONDITIONS

– Chronic Intracavernous Injection Therapy

– Dupuytren contracture

– ED (venoocclusive dysfunction)

– Leporionic disease (Plantar fascitis)

– Paget disease

– Leporionic disease (Plantar fascitis)

– Psoriatic arthritis

– Urethral stricture

– Hypoplasia

– Genital trauma

– Liposarcoma

– Penile pain syndrome

– Penile fracture, trauma, or contusion

– Penile surgery

– Penile pain syndrome

– Penile prosthesis problem: 5-shaped or sigmoid curvature with buckling of prosthetic cylinders that are too long; pain also suggests infected prosthesis components

– Priapism

– Psychiatric causes of pain

– Pubic neuralgia

– Referred pain, GI (rectum, hemorrhoids, fistula, fissures)

– Referred pain, GU (prostatitis, urethritis, proctitis, retention, urethral, urethral calculus)

– Reflected syndrome

– STD (herpes, chancre)

– Torn frenulum

– Trauma (ESW, penile fracture)

– Urethral foreign bodies

– Urethral stricture following urethroplasty

– Urethral stricture

IMAGING

– Radiograph of penile shaft if calcification is suspected.

– Duplex Doppler US with intracavernous pharmacologic injection to assess cavernous arterial function, presence of venoocclusive dysfunction, and degree of erectile curvature, lateral indentation or circumferential wasting.

– Nipple self-photography of erect penis using instant (Polaroid) or digital film imaging is useful to classify the extent of the curvature.

– Urethroscopy for urethral pathology

– Penile prosthesis problem: 5-shaped or sigmoid curvature with buckling of prosthetic cylinders that are too long; pain also suggests infected prosthesis components

– Priapism

– Psychiatric causes of pain

– Pubic neuralgia

– Referred pain, GI (rectum, hemorrhoids, fistula, fissures)

– Referred pain, GU (prostatitis, urethritis, proctitis, retention, urethral, urethral calculus)

– Reflected syndrome

– STD (herpes, chancre)

– Torn frenulum

– Trauma (ESW, penile fracture)

– Urethral foreign bodies

– Urethral stricture following urethroplasty

– Urethral stricture

DIAGNOSTIC TESTS & INTERPRETATION

Lab

– Usually not useful unless for workup of infections

– Usually useful

– Urinary symptoms and/or recurrent UTIs

– Urethroscopy for urethral pathology

– Urethral foreign bodies

– Urethral stricture following urethroplasty

– Urethral stricture
TREATMENT

GENERAL MEASURES

Identify the specific cause of the penile pain and/or curvature and treat accordingly.

MEDICATION

First Line

- PD
  - All oral agents yield insignificant therapeutic benefit:
    - Vitamin E (antioxidant), palbociclib (antifibrotic), colchicine (antifibrotic), tamoxifen (antifibrotic), L-carnitine (antioxidant), pentoxifylline
  - Paraphimosis
    - Urgent manual reduction with firm pressure ± local anesthetic (see section on paraphimosis for details)
  - Priapism
    - Irrigation and aspiration
    - Intravesical phenylephrine injection (100-500 mcg/mL)
  - Referred pain to penis or urethra should be aimed at treating primary problem

Second Line

- PD intralesional therapy
  - Plaque incision with graft interposition
  - Steroid therapy
  - Other intralesional agents (off-label) Verapamil, Collagenase clostridium histolyticum (CCH), antimicrobials
  - All oral agents yield insignificant therapeutic benefit:
    - Vitamin E (antioxidant), palbociclib (antifibrotic), colchicine (antifibrotic), tamoxifen (antifibrotic), L-carnitine (antioxidant), pentoxifylline
  - Paraphimosis
    - Urgent manual reduction with firm pressure ± local anesthetic (see section on paraphimosis for details)
  - Priapism
    - Irrigation and aspiration
    - Intravesical phenylephrine injection (100-500 mcg/mL)
  - Referred pain to penis or urethra should be aimed at treating primary problem

Additional Therapies

- Paraphimosis
  - See specific topic for surgical correction
  - Penile fracture
    - See specific topic for surgical correction
  - Priapism
    - Local anesthetic ± regional anesthetic

ADDITIONAL TREATMENT

Radiation Therapy

Indications

- PD or surgical repair

COMPLICATIONS

- Referred pain to penis or urethra

ONGOING CARE

PROGNOSIS

- Prognosis dependent on primary etiology of penile curvature and/or pain.
- Surgical straightening of erection is predictably successful (>95%).
- Shortened penile length and sensory loss may be noted postoperatively.

COMPICATIONS

- Residual pain and curvature
- Dyspareunia
- Erectile dysfunction and loss of penile length due to PD or surgical repair

FOLLOW-UP

Patient Monitoring

Periodic monitoring of erectile function, penile length, and sensory function.

Patient Resources

- The Peyronie Disease Society (www.peyroniesociety.org)
- Urology Care Foundation (http://www.urologyhealth.org/urology/index.cfm?article=115)

PENIS, CUTANEOUS LESION
Kiranpeet K. Khurana, MD
Edmund S. Sabanegh, Jr., MD

BASICS
DESCRIPTION
– Cremasteric, benign, premalignant, malignant
– May be male genitalia-specific (primary) or associated with other cutaneous lesions or systemic disease (secondary)
– May occur at any age

EPIDEMIOLOGY
Prevalence
Varies widely by etiology
Incidence

RISK FACTORS
Systemic disease, irritant or allergic, sexual contact, trauma, uncircumcised penis, family history, inflammation, infections, medications, local skin trauma, obesity, age, smoking

GENETICS
– Reiter syndrome: Associated with HLA-B27 haplotype
– Hailey–Hailey disease: Autosomal dominant
– Perilecan: Associated with altered expression of P53, FAS, c-erb, myc, Rb genes

PATHOPHYSIOLOGY
– Idiopathic, allergic, infectious, autoimmune, inflammatory, sensory, sexual transmission, genetic
– Lesions appear similar; biopsy often needed for diagnosis

ASSOCIATED CONDITIONS
– Leiden–rheumatoid syndrome: increase in size and number of subcutaneous keloidal lesions sometimes signifying internal malignancy
– Stevens–johnson syndrome and toxic epidermal necrolysis: Protracted upper respiratory illness followed by life-threatening desquamating lesions due to medications, infections, or cancers
– Poriodic: Lesions under preputial skin, genitals, or prepuce
– Reiter syndrome (reactive arthritis): Urethritis, arthritus, conjunctivitis, Cervicofacial balanitis
– Behcet disease: Painful ulcers found in 37–89% of patients, mostly on mouth (80%), but glans and shaft also affected
– Inflammatory bowel disease: Arterial thrombosis of penis, periurethral, and perineal granulomas on biopsy, also pyoderma gangrenosum
– Hailey–Hailey disease: Vesiculobullous rash
– Diabetes: Pierce
– HIV: Kaposi sarcoma, serebic dermatitis

GENERAL PREVENTION
– Cremasteric in some cases
– Proper hygiene
– Safe sex practices
– Avoid contact with allergens or irritants

DIAGNOSIS
HISTORY
– Age
– Symptoms: Pain, pruritus, burning, discharge
– Location: Scrotum, glans, shaft, preputial skin, urethral/bladder lining, other sites
– Duration
– Rate of onset: Acute or chronic
– Exposures: New bath/laundry soap, lotions, oils, travel (exotic plants, animals, insects, people), shared towels/linens, new medications, industrial, chemical
– Sexual history: Sexual partner with lesions
– Trauma
– History of systemic diseases or cancers
– Allergies
– Family history
– Previous treatment

PHYSICAL EXAM
– Examine and describe lesion(s): – Elevated, nonelevated
– Color of lesion
– Morphology of lesion
– Configuration of lesion (linear vs. serpiginous)
– Degree of margination
– Degree of firmness
– Examine genitalia: Circumcised, uncircumcised, local skin
– Degree of firmness
– Morphology of lesion
– Color of lesion
– Previous treatment
– Family history
– Previous treatment

DIAGNOSIS
HISTORY
– Age
– Symptoms: Pain, pruritus, burning, discharge
– Location: Scrotum, glans, shaft, preputial skin, urethral/bladder lining, other sites
– Duration
– Rate of onset: Acute or chronic
– Exposures: New bath/laundry soap, lotions, oils, travel (exotic plants, animals, insects, people), shared towels/linens, new medications, industrial, chemical
– Sexual history: Sexual partner with lesions
– Trauma
– History of systemic diseases or cancers
– Allergies
– Family history
– Previous treatment

PHYSICAL EXAM
– Examine and describe lesion(s): – Elevated, nonelevated
– Color of lesion
– Morphology of lesion
– Configuration of lesion (linear vs. serpiginous)
– Degree of margination
– Degree of firmness
– Examine genitalia: Circumcised, uncircumcised, proper placement of foreskin
– Describe primary lesion(s) (1/4A):
  – Pearly penile papule: Small, white/flesh colored, 0.5 cm, solid, dome-shaped
  – Plaque: >0.5 cm, solid, elevated, well-circumscribed
  – Vesicle: <0.5 cm, fluid-filled, well-circumscribed

DIFFERENTIAL DIAGNOSIS
Common benign lesions (1/4A)
– Viral: Human papilloma virus infection with verruca vulgaris
– Acrochordon: “Skin tag”
– Angiokeratoma of Fordyce: Red papules on penis, scrotum, eschara of dermal blood vessels
– Inflammatory: Vasculitis: Arterial, venous, lymphatic
– Infected: Due to sexually transmitted disease or other infection
– Neoplastic: Benign, premalignant, malignant

IMAGING
– If locally advanced lesion or internal lesions/tumors/malignancies suspected
– Workup for associated abnormalities

PROCEDURE/SURGERY
– Cryosurgery: Lesions are treated by freezing
– Excision: Lesion is surgically removed

PATHOLOGIC FINDINGS
– Depth of lesion
– Exam of epidermis, dermis, and subcutaneous tissue and any changes noted
– Infiltration with other cells or infectious agents

DIAGNOSTIC TESTS & INTERPRETATION
Lab
– Urinalysis, Gram stain, culture
– Complete blood count
– Sexen chemistry profile
– STD screening if suspected
Common benign lesions (1)[A]:

- Lipomas
- Papillomas
- Sebaceous cysts
- Hemangiomas

Infections and infestations (1)[A]

- Noninfectious ulcers, lesions extending to dermis
- Vesicobullous disorders, autoimmune blisters
- Fixed drug eruption

TREATMENT

If left untreated, lesions may progress locally or systemically.

General Measures

- Local care
- Analgesics
- Topical care
- Systemic care

For more information, visit: [source](http://www.aad.org/skin-conditions/differential-diagnosis)

MEDICATION

First Line

- Topical antibiotics
- Antiviral agents

Second Line

- Systemic antibiotics

SURGERY/OTHER PROCEDURES

- Surgical excision
- Laser ablation
- Electrocautery

Additional Therapy

- Brachytherapy
- Immunotherapy

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Massage therapy
- Acupuncture

ONGOING CARE

- Follow-up visits
- Education

FOR MORE INFORMATION

- [American Academy of Dermatology](http://www.aad.org)
- [American Urological Association](http://www.auanet.org)

ADDITIONAL READING

PHENOMENA

- Lipomas: Topical corticosteroids, diathermy, or systemic treatment
- Lipomas: Biopsy to exclude SCC
- Long-term follow-up required
- Cytotoxic agents
- Oral corticosteroids, immunosuppressive therapy
- Oral corticosteroids, immunosuppressive therapy
- Topical corticosteroids
-systemic treatment

PHENOMENA
**PATHOPHYSIOLOGY**

- Risk factors: 
  - Human papilloma virus (HPV) types 16, 18, 31, and 33 (associated with 45–80%)
  - Presence of foreskin and/or phimosis
  - Presence of smegma accumulation
  - Poor hygiene
  - Presence of foreskin and/or phimosis
  - Human papilloma virus (HPV) types 16, 18, 31, and 33
  - Accounts for up to 10% of cancers in men in South America.

**EPIDEMIOLOGY**

- Incidence: 
  - Rare in developed countries. Approximately 1,640 new cases annually in US with approximately 320 deaths in 2014.
  - Hispanics are more commonly affected than whites.
  - Rare in developed countries. Approximately 1,640 new cases annually in US with approximately 320 deaths in 2014.

- Prevalence: 
  - Accounts for 0.4–0.6% of cancers in men

**RISK FACTORS**

- Human papilloma virus (HPV) types 16, 18, 31, and 33 (associated with 45–80%)
- Presence of foreskin and/or phimosis
- Poor hygiene
- Sexually transmitted disease (STD)
- HIV infection
- Chronic inflammation
- Lichen sclerosus
- Smoking

**GENETICS**

- HPV-associated DNA and chromosomal changes
- Smear that forms from desquamated epithelial cells is thought to be a primary instigating factor in penile cancer; good hygiene and circumcision limit smegma accumulation
- Penile SCC spreads by a reliable pattern: Superficial invaginal lymph nodes to deep inguinal lymph nodes

**DESCRIPTION**

- The majority of penile carcinomas are squamous cell carcinoma (SCC) histology
- Can be SCC in situ (erythroplasia of Queyrat, Bowen disease of the penis, boweroid papillosis), low-grade noninvasive (eg, verruous carcinoma), or invasive carcinoma
- Other rare types of penile cancer histologies include adenoid- and adenosquamous carcinoma, basal cell carcinoma, melanoma, sarcomas, Kaposi sarcoma, neuroendocrine (small cell) undifferentiated carcinoma, sebaceous gland carcinoma, and rarely, metastases from other sites (prostate, bladder, colon, kidney)
- Inguinal and pelvic lymph nodes are common sites of metastases

**DIAGNOSIS**

**HISTORY**

- Induration, erythema, nodularity of prepuce and/or shaft
- Bleeding ulcer on glans and/or penis shaft
- Inguinal adenopathy
- Patients often deny or ignore symptoms resulting in presentation at advanced stage

**PHYSICAL EXAM**

- Induration, erythema, nodularity of prepuce and/or shaft
- Bleeding ulcer on glans and/or penis shaft
- Inguinal adenopathy
- Patients often deny or ignore symptoms resulting in presentation at advanced stage

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- Serum CBC, electrolytes (including calcium), and liver function studies
- Urinalysis, urine culture

**Imaging**

- US or MRI of penis for local tumor (T) staging
- CT/ MRI of penis and regional lymph nodes to evaluate for lymphadenopathy and metastatic disease

**Pathologic Findings**

- Most malignancies involve the epithelial surface of the penis.
- Subtypes of SCC:
  - Well differentiated (50–90%)
  - Moderately differentiated (>50% anaplastic cells)
  - Poorly differentiated (<10% anaplastic cells)

**DIFFERENTIAL DIAGNOSIS**

- BKO
- Brown disease (red, flat papules on keratinized skin of the penis typically penile shaft)
- Erythroplasia of Queyrat; shiny red patches on mucosal surfaces (glans and prepuce if uncircumcised)
- Buschke–Löwenstein tumor, and giant condyloma are terms used to describe infrequently seen rare tumors that may invade locally but do not metastasize. Mostly considered to be benign, but malignant degeneration has been reported

**ASSOCIATED CONDITIONS**

- Erythroplasia of Queyrat, Bowen disease of the penis, boweroid papillosis
- Human papilloma virus (HPV) types 16, 18, 31, and 33
- Accounts for up to 10% of cancers in men in South America.
- Hispanic population is more commonly affected than whites.
- Rare in developed countries. Approximately 1,640 new cases annually in US with approximately 320 deaths in 2014.
**TREATMENT**

**GENERAL MEASURES**
- Treatment typically based on grade and stage of primary tumor (1)
- Radiotherapy
  - Fine-needle aspiration (FNA)
  - 4-wk course of oral antibiotics followed by repeat physical exam

**MEDICATION**

**First Line**
- Topical: Imiquimod 5% cream applied for 5 d/wk for 4–6 wk or 5–10% cream every other day for 4–6 wk

**Second Line**
-以外

**SURGERY/OTHER PROCEDURES**
- Primary lesions
  - T1b lesions
  - Lyphadenectomy
  - Wide local excision, Mohs surgery, glansectomy, glansectomy
  - T1 grade 1–2
  - Mohs, wide local excision
  - External beam radiation therapy
  - Radiotherapy with interstitial placement
  - Laser ablation
  - T1 grade 3–4 or T1c
  - Partial penectomy
  - Pelvic lymph node dissection if ≥ 4 cm

- Secondary lesions
- Tis/Ta lesions
- Lasix 5% cream applied for 5 d/wk
- 6-wk course of oral antibiotics followed by repeat physical exam
- Fine-needle aspiration (FNA)

- When applicable, UNL associated with improved disease-specific survival

**COMPLICATIONS**
- Infections
- Vascular injury
- Lymphedema
- Wound breakdown (16%)
- Seroma (24%)
- Infection (43%)
- Urethral stenosis
- Vesical injury
- Erosion of lymphadenopathy into femoral vessels

**FOLLOW-UP**

- Close inspection for local recurrence usually every 3 mo for 5 yr (frequency depends on grade and stage)
- Consider imaging for ambiguous findings on physical exam

**Patient Resources**

**ICD9**
- 170.0 Kaposi’s sarcoma, skin
- 174.9 Malignant neoplasm of penis, unspecified
- 233.5 Carcinoma in situ of penis

**ICD10**
- C46.0 Carcinoma of penis
- C46.9 Malignant neoplasm of penis, unspecified
- D07.4 Carcinoma in situ of penis

**REFERENCES**

**ADDITIONAL READING**

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- External radiation to primary lesion or inguinal lymph nodes
- Typical doses are 50–60 Gy over 4–6 wk
- Intermal brachytherapy for clinically indicated lesions

**Additional Therapies**
- Neoadjuvant chemotherapy
  - TIP: Brachytherapy, paclitaxel, cisplatin
  - Adjunct for high-risk disease
- Pelvic lymph node involvement
- Neoadjuvant chemotherapy

- Metastatic disease
  - TIP
  - Clinical trial
  - Supportive/palliative care

**ONGOING CARE**

**PROGNOSIS**
- Depends on stage and nodal status
- Overall survival for men with node-negative disease is 85–90%
- 20–30% of men with inguinal lymph node metastasis will have pelvic lymph node metastasis
- Pelvic nodal metastasis have a 10%–5 yr survival
- When applicable, UNL associated with improved disease-specific survival

**CODES**

**CLINICAL/SURGICAL PEARLS**
- Grade and stage associated with prognosis
- PNA of palpable nodes is preferred over 6-wk course of oral antibiotics
- Modified ELD is associated with improved nodal clearance
- Bulky inguinital lymph node metastases should be managed by multidisciplinary therapy consisting of neoadjuvant systemic chemotherapy followed by surgical resection (± radiation)
PATHOPHYSIOLOGY
Incidence
- Penile wounds and penetrating injuries make up 40–60% of battlefield wound injuries during times of war. Likely due to lack of protection to external genitalia.
- In the battlefield, use of fragmentation devices (mines, IED) and high-velocity missiles cause a significantly greater percentage of genitourinary injuries to involve the penis and genitalia.
- Pelvic fracture infrequently seen in US, with incidence of 1 in 175,000 hospital admissions.
- Penile fractures are common in Iran where it is a state-sponsored sport.
- Retrograde ejaculation is common in patients prescribed penile constriction devices for the management of erectile dysfunction.

DIAGNOSIS
DESCRIPTION
Acute traumatic injury to the penis may be due to: blunt trauma (penile fracture to the erect penis), penetrating injury (stab wound, firearm, improvised explosive device [IED], or amputation), degloving (blunt force trauma to the erect penis), burns, human and animal bites, or constriction with reduced blood flow.

EPIDEMIOLOGY
Incidence
- Penile wound
- Penile strangulation
- Penile fractures
- Penile amputation
- Rupture of superficial dorsal vein
- Fournier gangrene
- Burn
- Penile “fracture”
- Penetrating injury
- Penile fracture:
  - Type of Injury
  - Magnitude of force transmitted
  - Type of object in penetrating injury
  - Pattern of erections, ecchymosis
  - Associated abdominal pain, nausea, emesis
  - Typical results from impact with partner’s pubic symphysis or perineum
  - Mantle of deep fascia (Buck’s fascia) and superficial skin vascularized all protect from ischemic loss of the penis
  - Penile strangulation:
  - Constricts blood flow, leading to edema, ischemia, constriction
  - Poor perfusion of the corpora cavernosa
  - Adult patients: Penile constricting devices designed for sexual enhancement
  - Pediatric patients: Hair or string causes constriction
  - Associated injuries are common due to the proximity to other pelvic organs
  - Degloving injuries: Loss of superficial penile tissue (skin and dartos fascia)

ASSOCIATED CONDITIONS
- Injury to scrotum, testicles, urethra, or rectum may accompany penile trauma
- Pelvic fracture

GENERAL DIAGNOSIS
- History
  - Type of injury
  - Magnitude of force transmitted
  - Type of object in penetrating injury
  - Pattern of erections, ecchymosis
  - Associated abdominal pain, nausea, emesis
  - Typical results from impact with partner’s pubic symphysis or perineum
  - Mantle of deep fascia (Buck’s fascia) and superficial skin vascularized all protect from ischemic loss of the penis
  - Penile strangulation:
  - Constricts blood flow, leading to edema, ischemia, constriction
  - Poor perfusion of the corpora cavernosa
  - Adult patients: Penile constricting devices designed for sexual enhancement
  - Pediatric patients: Hair or string causes constriction
  - Associated injuries are common due to the proximity to other pelvic organs
  - Degloving injuries: Loss of superficial penile tissue (skin and dartos fascia)

BASICS
- Transferring energy to the penis is most devastating due to penetrating mechanisms
- Adult patients: Penile constricting devices
- Pediatric patients: Hair or string causes constriction

RISK FACTORS
- Occupational (mining, farming, heavy machinery)
- Bicycling is leading sport associated with injury to the external genitalia

GENETICS
- N/A

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urethral culture if infection suspected
- CBC
- For delayed presentation with abscess formation, culture abscesses

Imaging
- Suspect of urethral injury warrants evaluation with retrograde urethrography to evaluate for the presence of injury and injury location
- Penile fracture:
  - MRI or US if useful if rupture of superficial dorsal vein suspected
  - Cavernosography historically described
  - Rectal ultrasound or CT scan may be useful if suspicious for associated injuries

DIFFERENTIAL DIAGNOSIS
- Burn
  - Constriction injury (band or other device placed around base of penis) can include medically approved devices
  - Firefighter's burn
  - Human or animal bite
  - Laceration
  - Penetrating injury
  - Penile “fracture”
  - Rupture of superficial dorsal vein
  - Penile amputation

PHYSICAL EXAM
- Pattern of erythema, ecchymosis
- Assess for injuries of adjacent organs
- Blood at meatus concerning for urethral injury
- Size of laceration, if present
- Transilluminate any palpable scrotal mass
- Symmetry of the penis
- Presence of injury and injury location.

TREATMENT
GENERAL MEASURES
- Establish the overall stability of the patient (1)
- Recognize and appropriately manage injuries to the external genitalia
- Maintain high index of suspicion for urethral injury and assess with retrograde urethrography or cystoscopy
- Association for the Surgery of Trauma (AST) organ injury scale classification (2):
  - I: Cavernosal laceration/contusion
  - II: Buck’s fascia (cavernosal) laceration without tissue loss
  - III: Cavernosal avulsion, laceration through glansmeatus, cavernosal/urethral defect < 2 cm
  - IV: Partial penectomy, cavernosal or urethral defect > 2 cm
  - V: Total penectomy

- For burns see section on “Burns, External Genitalia, and Perineum”
Penile strangulation:
- Penile fracture:
  - Penile amputation
  - Primary skin closure is appropriate unless significant defects due to fracture, gunshot, or stab wound.
  - Surgical exploration is required in almost all cases of penile injury (3–5).

Penile injuries have high likelihood of associated injuries to the external and internal pelvic organs.

With penile fracture there is 10–22% associated urethral injury; surgical repair is associated with lower rates of erectile dysfunction or curvature.

Penile injuries have high likelihood of associated injuries to the external and internal pelvic organs. Urethral injury must be excluded.

Tetanus prophylaxis for all penetrating injuries.

Human bites:
- Should not be closed; antibiotic therapy includes oral dicloxacillin or cephalaxin.

**Additional Reading**
- See Also (Topic, Algorithm, Media):
  - Bites to Penis (Animal and Human)
  - Burns, External Genitalia and Perineum
  - Penis, Transection
  - Penis, Trauma Algorithm
  - Penis, Trauma Images
  - Scrotum and Testicle, Trauma
  - Taghaandan

**Prognosis**
- Most penile injuries can be successfully repaired with low rate of erectile dysfunction when immediate revascularization is performed.
- Delayed repair or nonoperative approach to penile injuries may lead to penile curvature and erectile dysfunction.
- Even after penile amputation, with successful replantation patients can have sensation with erectile function.

**Complications**
- Decreased sensation
- Impotence
- Penile curvature
- Skin loss (particularly with nonmicrovascular penile replantation)
- Urethral stricture
- Urethral stricture or fistula
- Wound infections

**Follow-Up**
- Patient monitoring is required for detection for complications.
- Traumatic injury may result in erectile dysfunction requiring additional therapy.

**Patient Monitoring**
- Euvolemic status should be maintained.
- Adequate fluid resuscitation is critical.
- Urinary drainage should be maintained.
- Temperature control should be maintained.

**Pharmacology**
- Analgesics (local/regional/spinal/local anesthetic):
  - Narcotics (morphine, fentanyl, hydromorphone, meperidine)
  - Benzodiazepines (diazepam, lorazepam)
  - Nonsteroidal anti-inflammatory drugs (ibuprofen, ketorolac)

**Surgical Considerations**
- Penile fracture:
  - Circumferential incision via subcoronal approach with excision of hematoma
  - Close cavernous injuries with absorbable suture (5-0 PDS)
  - Explore for urethral injuries and, if present, repair (5-0 PDS)

**Penile lacerations**:
- Incision of offending agent if possible (cat hair, string, band, soft rings with scissors).
- Solid constraining devices: Attempt removal with lubrication; detailed penile compression with manual pressure may decrease tissue edema long enough to remove foreign body.
- Some devices may require ring cutters, operative drills, industrial drills, various saws; protect phallic with tongue depressor, markable retractor.

**Penile amputation**
- Avulsion (leaving a stump): Neovascularization is a possibility.
- Preservation of the corpus cavernosum at the base of the penis is important.

**Penile amputation**
- Incision of offending agent if possible (cut hair, string, band, soft rings with scissors).
- Incision of offending agent if possible (cut hair, string, band, soft rings with scissors).
- Penile amputation:
  - Euvolemic status should be maintained.
  - Adequate fluid resuscitation is critical.
  - Urinary drainage should be maintained.
  - Temperature control should be maintained.

**Penile amputation**

**Penile amputation**
- Incision of offending agent if possible (cut hair, string, band, soft rings with scissors).
- Incision of offending agent if possible (cut hair, string, band, soft rings with scissors).
PEYRONIE DISEASE
Irvin H. Hirsch, MD

ASSOCIATED CONDITIONS
- ED: Occurs in 20% men with PD (1,3)
- Diabetes, Hypertension, Dyslipidemia, Smoking, Coronary disease
- PD is found in 10% men with ED
- Urethral stenosis may occur

GENERAL PREVENTION
Avoidance of penile trauma during intercourse

DIAGNOSIS

HISTORY
- Duration and onset of symptoms, history of erectile trauma. Slight pain or snapping during intercourse
- Pain: With or without erection, during intercourse
- Sensory Loss, partner’s perception

PHYSICAL EXAM
- Erections: Quantify rigidity; sufficient for intercourse
- Pain: With or without erection, during intercourse
- Distress and depression resulting from Peyronie disease

DIAGNOSTIC TESTS & INTERPRETATION
- Lab: Imaging
- No imaging necessary for diagnosis/medical therapy

Prognostic indicators:
- Acute phase:
  - Occurs in 1st 6–18 mo
  - Inflammation of fibroblasts, myofibroblasts, and collagen deposition
  - Pain with erection, slight penile curvature, and nodular formation
- Chronic phase:
  - Medical therapy most effective in acute phase
  - Remodeling of connective tissue into a dense fibrotic plaque
- Stable plaque size, penile curvature possibly causing ED, erections less painful

Natural history: Minority of patients (10%) will have spontaneous regression, yet most patients will not develop disease significant enough to require surgery.

DIAGNOSIS
- Excess collagen deposition and inflammatory infiltrate is found in the tunica albuginea
- Pale plaque: Significant fibrosis
- Deep plaque: Muscle and perineal connective tissue

DIFFERENTIAL DIAGNOSIS
- Cancer: Primary or metastatic to corpora
- Chordee: Usually associated with hypospadias
- Keloid syndrome: Fibrosis of the corpus spongiosum that limits expansion of the ventral corpus cavernosum
- Penile fracture (hematoma)

TREATMENT

GENERAL MEASURES
- A small percent of men will undergo spontaneous remission.
- ED is not a common 1st-line option but ultimately offers definitive resolution of curvature and deformity
- The lack of randomized, placebo-controlled trials makes evaluation of efficacy and comparison between any medical therapies for PD difficult.
- Patients most likely to respond to medical therapy: Young patients in acute phase (1,3)
- Introduction of sexual activity incites healing, trauma. Severe pain or snap or popping during intercourse

PHYSICAL EXAM
- Erections: Quantify rigidity; sufficient for intercourse
- Pain: With or without erection, during intercourse
- Sensory Loss, partner’s perception

DIAGNOSTIC TESTS & INTERPRETATION
- Lab: Imaging
- No imaging necessary for diagnosis/medical therapy

MEDICATION

GENERAL MEASURES
- Oral therapy (2):
  - Acetyl-L-carnitine, 400 mg PO BID
  - Growth factor blocker and anti-inflammatory

DIFERENTIAL DIAGNOSIS
- Cancer: Primary or metastatic to corpora
- Chordee: Usually associated with hypospadias
- Keloid syndrome: Fibrosis of the corpus spongiosum that limits expansion of the ventral corpus cavernosum
- Penile fracture (hematoma)

TREATMENT

GENERAL MEASURES
- A small percent of men will undergo spontaneous remission.
- Surgery is not a common 1st-line option but ultimately offers definitive resolution of curvature and deformity
- The lack of randomized, placebo-controlled trials makes evaluation of efficacy and comparison between any medical therapies for PD difficult.
- Patients most likely to respond to medical therapy: Young patients in acute phase (1,3)
- All medical therapies provide varying decrease in pain, curvature, or plaque size; complete resolution of curvature is uncommon.

MEDICATION

First Line
- Oral therapy (2)
  - No therapy has proven more or less effective than another

TREATMENT

GENERAL MEASURES
- A small percent of men will undergo spontaneous remission.
- Surgery is not a common 1st-line option but ultimately offers definitive resolution of curvature and deformity
- The lack of randomized, placebo-controlled trials makes evaluation of efficacy and comparison between any medical therapies for PD difficult.
- Patients most likely to respond to medical therapy: Young patients in acute phase (1,3)
- All medical therapies provide varying decrease in pain, curvature, or plaque size; complete resolution of curvature is uncommon.

MEDICATION

First Line
- Oral therapy (2)
  - No therapy has proven more or less effective than another

TREATMENT

- The lack of randomized, placebo-controlled trials makes evaluation of efficacy and comparison between any medical therapies for PD difficult.
- Patients most likely to respond to medical therapy: Young patients in acute phase (1,3)
- All medical therapies provide varying decrease in pain, curvature, or plaque size; complete resolution of curvature is uncommon.
SURGERY/OTHER PROCEDURES

- Indications: Curvature or erectile dysfunction that preclude intercourse (CHC)
- Patient must be in chronic phase with stable painless plaques
- Progressive US with intracavernous vasoactive challenge is useful to evaluate vasculature and avoid shortening
- Candidates: Shorter penis, proximal plaque, severe erosion/granuloma, penile shortening
- Relative to corporal plaque, plication of opposite side is not recommended
- Intralesional corticosteroids no longer recommended due to local side effects

Second Line

Radiation Therapy

- Mixed results reported; not recommended
- Extracorporeal shockwave therapy: No good studies to support efficacy; not recommended
- Additional Therapies
  - Mixed results reported; not recommended
  - Carnitine supplementation: Mixed results

ONGOING CARE

Erectile Dysfunction/Impotence (ED)

- Patient Monitoring
  - Patients should be re-examined frequently to assess disease status and response to therapy.
  - Depression can be associated

FOLLOW-UP

- Patients with mild curvature and no evidence of erectile dysfunction should be observed.
- Recent studies suggest up to 48% of men with PD should be considered for mental health screening.

PEARLS

- Diagnosis of Peyronie disease is exclusively based on history and physical exam.
- Patients with mild curvature and no evidence of erectile dysfunction should be observed.
- New data suggests that CCH can significantly reduce the symptoms of Peyronie disease.
- The ideal candidate for CCH is having Peyronie disease for at least 12 mo, has stable disease, and a curvature of 30 degrees or greater.

REFERENCES

PHENOCROMOCYTOMA
Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

PATHOPHYSIOLOGY
- Tumors arise from chromaffin cells of neural crest origin in the sympathetic nervous system
- Rule of 10 (10% bilateral, 10% extra-adrenal, 10% familial, 10% malignant) no longer accurate:
  - 10% of sporadic tumors bilateral
  - Extra-adrenal up to 20%
  - Hereditary 20–30%
  - Malignant up to 5% in adrenal pheochromocytoma
- Histologic determination of malignancy is not possible; diagnosed based on metastases
- Tumors contain enzymes necessary to convert tyrosine to catecholamines
- Clinical manifestations secondary to the release of these catecholamines, NE, and EPI
- Sustained hypertension with superimposed paroxysms: 50% incidence
- Paroxysmal HTNL: dramatic attacks, 3–4 times a week
- Sustained hypertension with superimposed paroxysms: 10% incidence
- Fine tremors, pallor, perspiration
- Papilledema, accelerated hypertensive retinopathy

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Plasma or urinary fractionated metabolites are the best screening tests:
  - Chromaffin cells metabolize NE to NMN and EPI to MN
- Fractionated metabolites refer to MN and NMN
- Both plasma metabolites and urine metabolites are acceptable options; current recommendations do not recommend either test over the other
- Plasma metabolites have a high sensitivity (96–100%) but poor specificity, particularly in older patients (77–89%) (2)
- Urine test: 24 hr urine for NE, EPI, MN, NMN, and VMA
- VMA highly specific (95%) but not sensitive (64%)
- If urinary values are 3 times normal, then proceed to localize the tumor
- If urinary values are 3 times normal and suspicious, then repeat the test and proceed to pharmacoergic testing
- Plasma metanephrine testing
  - No caffeine prior
  - No acetaminophen for 5 days prior
  - No aspirin for 24 hr prior to draw
  - MN > 96 pg/mL, NMN > 130 pg/mL, or total metanephrines > 200 abnormal (2)
- Pharmacologic testing:
  - Stimulation and suppression tests are generally not utilized
  - Provocative tests dangerous, with several reported deaths
  - Clonidine suppression test:
    - Centrally acting α2 agonist that suppresses sympathetic outflow
    - Normally results in decreased BP and lower levels of plasma catecholamines
    - Draw blood for NE/EPI before and 3 hr after administering clonidine (0.3 mg/kg)
    - Plasma metanephrines have a high sensitivity (96–100%) but poor specificity, particularly in older patients (77–89%) (2)
- Histologic determination of malignancy is not possible; diagnosed based on metastases

BASICS
DESCRIPTION
- Phaeochromocytoma is a rare catecholamine-producing tumor arising from chromaffin cells in the adrenal medulla
- Paragangliomas refer to lesions found in extra-adrenal sites arising from the sympathetic nervous system

EPIDEMIOLOGY
- Syndromes are all autosomal dominant
- Germ-line mutations specific to each syndrome
- Von Hippel–Lindau disease (retinal cerebellar hemangioblastomatosis): 10% with brain and spinal cord tumors
- Neurofibromatosis Type 1 (von Recklinghausen disease): 40% with pheochromocytoma
- MEN IIB (MEN III): Pheochromocytoma (50%), medullary carcinoma of the thyroid (50%), and parathyroid adenoma (25%)
- MEN II (MEN III): Phaeochromocytoma (50%), medullary carcinoma of the thyroid (50%), and parathyroid adenoma (25%)
- MEN IIA
- NF1
- NF2

RISK FACTORS
- Familial tumors associated with MEN multiple endocrine neoplasia (MEN) syndromes:
  - MEN IIA (Sipple syndrome):
  - Phaeochromocytoma (50%), medullary carcinoma of the thyroid (50%), and parathyroid adenoma (25%)
  - MEN II (MEN III):
    - Phaeochromocytoma (50%), medullary carcinoma of the thyroid (50%), ganglioneuromatosis, multiple mucosal neuromas (of eyelids, lips, tongue)
    - Neurofibromatosis Type 1 (von Recklinghausen syndrome): 1% has phaeochromocytoma; 5% of patients with neurofibromatosis have neurofibromatosis
    - Von Hippel–Lindau disease (retinal cerebellar hemangioblastomatosis): 10% with pheochromocytoma

GENETICS
- Germ-line mutations specific to each syndrome
- Syndromes are all autosomal dominant
- MEN IIA: Mutation in intracellular domain of RET protein
- Von Hippel–Lindau: VHL tumor suppressor gene on chromosome 3p35
- Von Recklinghausen syndrome: Neurofibromatosis type 1 gene
- Familial neuro-endocrine paraganglioma: Sustinate dehydrogenase gene (1)

HISTORY
- Most patients symptomatic
- Paroxysmal HTNL with severe headache, drenching perspiration, palpitation, and palpitations
- Additional symptoms include nervousness, tremor, palpitations in the chest and abdomen, nausea, fever, and flushing

PHYSICAL EXAM
- Hypertension: Most common sign
- Palpable tumor (rare)
- Fine tremors, pallor, perspiration
- Papilledema, accelerated hypertensive retinopathy
- Sustained hypertension with superimposed paroxysms: 10% incidence
- Paroxysmal HTNL: dramatic attacks, 3–4 times a week
- Sustained hypertension with superimposed paroxysms: 10% incidence
- Fine tremors, palpitation
- Palpable tumor (rare)
- Accelerated hypertensive retinopathy: Papilledema, exudate, A-V nicking
- Raynaud phenomenon
- Hypertrophia cardiaca

IMAGING
- Localization studies should be started only if clinical evidence for the tumor’s existence is strong
- Renal, ureteric, and suprarenal with very high IVU/MRI
- CT or MRI for initial localization
- Neither CT nor MRI is recommended above the diaphragm
- Phaeochromocytoma characteristically hypointense on T2-weighted images
- Scan abdomen and pelvis 1st
- If no tumor found, scan chest and neck
- Metastases in long bones may be missed
- Cannot reliably differentiate between types of adrenal tumors
**PHEOCHROMOCYTOMA**

- Iodine-123-labeled MIBG scintigraphy is more specific for localization of pheo: – Provides both anatomic and functional characterization of the tumor – Concentrated in sympathomedullary tissue through the catecholamine pump – Useful to evaluate for residual or multiple tumors, and MEN syndromes

**Diagnostic Procedures/Surgery**

**Alert**

- Biopsy of adrenal mass should not be performed until pheochromocytoma has been ruled out.

**Pathologic Findings**

- Sporadic tumors are solitary, well-circumscribed, and encapsulated.
- Malignant phae (cannot be differentiated from benign phae) by exam of primary tumor. Malignant phae is defined by metastasis.

**Differential Diagnosis**

- Essential HTN
- Renovascular disease
- Anxiety, tension states, psychoneurosis (rarely)
- Paroxysmal tachycardia
- Hyperthyroidism
- Renovascular disease
- Anemia (rarely)
- Acute hypertension (rarely)
- Nephrologic diseases
- Malignant phae

**TREATMENT**

**General Measures**

- Surgical removal of the tumor is the only definitive method of treatment.

**Medication**

**First Line**

- Alpha-adrenergic blocking agents essential before surgery:
  - Phenoxybenzamine (0-40 mg bid or tid)
  - Prazosin (1-10 mg bid)

- Beta-blocking agents contraindicated in absence of established ad blockades
  - Use only with concurrent cardiac arrhythmias or persistent tachycardia
  - Blockade of peripheral vasodilator beta-adrenergic receptors results in unopposed alpha-adrenergic stimulation with resultant hypertension

- Can precipitate cardiomyopathy and pulmonary edema due to chronic catecholamine excess

**Second Line**

See “Additional Therapies”

**SURGERY/OTHER PROCEDURES**

- Preoperative adrenal blockade is mandatory
- Volume expansion with high sodium diet
- Initial surgery aimed at early ligation and division of the adrenal vein before manipulation of the tumor
- Preoperative adrenergic blockade is mandatory
- Iodine-123-MIBG radiation is the most effective radiation therapy
- Combination chemotherapy with cytokines and interferon may be considered

**Additional Therapies**

- Malignant pheochromocytoma
  - Iodine-123-MIBG scintigraphy is more specific for localization of pheo
  - Initial dissection aimed at early ligation and division of the adrenal vein before manipulation of the tumor
  - Malignant pheochromocytoma is slow growing
  - Re-SECTION should be attempted
  - Large masses can be debulked for palliative surgery

**Follow-up**

- Ongoing care
- 10-yr survival for nonmalignant tumors: >80%
- 5-yr survival for malignant pheo: 34-46%
- Currenty no cure for malignant pheo

**Complications**

- Renal insufficiency
- Hypertensive crisis
- Cerebral vascular accident
- Hemorrhagic necrosis
- Neurogenic pulmonary edema
- Neurogenic pulmonary edema

**Pearls**

**References**

**Additional Reading**

**See Also** (Topic, Algorithm, Media)

- Adrenal Mass
- Adrenal Mass, Algorithm
- Multiple Endocrine Neoplasia (MEN I and II)
- Phaeochromocytoma Image

**Codes**

- ICD9: 237.0 Benign neoplasm of adrenal gland
- ICD10: D35.00 Benign neoplasm of unspecified adrenal gland
- ICD10: D35.01 Benign neoplasm of right adrenal gland
- ICD10: D35.02 Benign neoplasm of left adrenal gland
- ICD10: D55.2 Benign neoplasm of left adrenal gland

**Clinical/Surgical Pearls**

- Hydration and adequate alpha-adrenergic blockade prior to surgery
- Laparoscopic adrenalectomy treatment of choice with early control and ligation of adrenal vein

**Patient Monitoring**

- Because of uncertainties about which tumors are malignant, measure urinary or plasma catecholamines 1-2 wk postoperatively and annually for 5 yr.
- BP should be monitored every month for the 1st 6 mo, then every 6 mo thereafter.
- 25% of patients have persistent HTN after surgery.

**Patient Resources**

PHIMOSIS AND PARAPHIMOSIS

Michael A. Poch, MD
Philippe E. Spiess, MD

BASICS

DESCRIPTION
- Phimosis (preputial stenosis) is the inability to retract the foreskin.
- Can be seen in children and adults
  - Physiologic (congenital) phimosis: Foreskin (prepuce) is usually not retractile in a newborn.
    - The majority can be retracted by 3–5 yr of age
  - Pathologic (acquired) phimosis: The prepuce cannot be retracted when previously possible or it has never been retractile and is associated with symptoms and/or complications
- Paraphimosis: The prepuce is retracted, left in position causing vascular engorgement of the glans preventing reduction

EPIDEMIOLOGY

Incidence
- Phimosis:
  - 10% nonretractile at 3–5
  - ≤1% nonretractile at puberty
- Paraphimosis:
  - 0.7% of uncircumcised boys

Prevalence
- N/A

RISK FACTORS
- Physiologic phimosis:
  - Local irritation and redness
  - Penile pain
  - Postvoid dribbling
  - Ballooning of the foreskin with voiding
  - Cracking or bleeding from the foreskin
- Penile discharge
  - Dysuria and/or other voiding symptoms
  - BXO

Paraphimosis:
- Hair or thread wraps around a child’s penis and causes penile edema or strangulation
- Diabetes mellitus
- Balanitis xerotica obliterans (BXO)
- Balanoposthitis
- Penile cancer

ASSOCIATED CONDITIONS
- Penis cancer
- Balanitis (inflammation of the glans)
- Posthitis (inflammation of the prepuce)
- Balanoposthitis
- Balanitis xerotica obliterans (BXO)
- Diabetic meatalitis

GENERAL PREVENTION
- Good hygiene
- Don’t prematurely manipulate the foreskin

DIAGNOSIS

HISTORY
- Was foreskin previously retractile?
- Recent urethral manipulation (Foley catheter placement, cystoscopy)
- Circumcision status
- Recent urethral manipulation (Foley catheter placement, cystoscopy)
- Was foreskin previously retractile?

GENERAL MEASURES
- Observation and reassurance
- Manual reduction technique:
  - 1st attempt manual compression for 5 min to reduce edema and reposition foreskin
- Manual reduction should be attempted 1st prior to medication or surgical procedure
- Hair/thread tourniquet:
  - Penile edema
  - Baloconic or circumcised
- Hair or thread wraps around a child’s penis and causes penile edema or strangulation

DIFFERENTIAL DIAGNOSIS
- Phimosis
  - Physiologic vs. pathologic
  - Trapped penis occurs when a dense cicatricial scar traps the penis under the preputial or coronal skin after neonatal circumcision.
  - BXO
- Paraphimosis
  - Penile edema
  - Postcircumcision cicatrix
  - Hair or thread tourniquet
- Urinary tract infection (UTI) or sexually transmitted infection (STI)
- BXO

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Usually not necessary unless symptoms of urinary tract infection (UTI) or sexually transmitted infection (STI) are present
- Imaging
  - Not usually performed

TREATMENT

GENERAL MEASURES
- In the elderly male undergoing bladder catheterization, failure to replace the foreskin to its normal reduced position may result in paraphimosis (1,2)

DIFFERENTIAL DIAGNOSIS
- Phimosis
  - Physiologic vs. pathologic
  - Trapped penis occurs when a dense cicatricial scar traps the penis under the preputial or coronal skin after neonatal circumcision.
  - BXO
- Paraphimosis
  - Penile edema
  - Postcircumcision cicatrix
  - Hair or thread tourniquet
  - Urinary tract infection (UTI) or sexually transmitted infection (STI)
  - BXO

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Usually not necessary unless symptoms of urinary tract infection (UTI) or sexually transmitted infection (STI) are present
- Imaging
  - Not usually performed

DIFFERENTIAL DIAGNOSIS
- Phimosis
  - Physiologic vs. pathologic
  - Trapped penis occurs when a dense cicatricial scar traps the penis under the preputial or coronal skin after neonatal circumcision.
  - BXO
- Paraphimosis
  - Penile edema
  - Postcircumcision cicatrix
  - Hair or thread tourniquet

Lab
- Usually not necessary unless symptoms of urinary tract infection (UTI) or sexually transmitted infection (STI) are present
- Imaging
  - Not usually performed

DIFFERENTIAL DIAGNOSIS
- Phimosis
  - Physiologic vs. pathologic
  - Trapped penis occurs when a dense cicatricial scar traps the penis under the preputial or coronal skin after neonatal circumcision.
  - BXO
- Paraphimosis
  - Penile edema
  - Postcircumcision cicatrix
  - Hair or thread tourniquet
  - Urinary tract infection (UTI) or sexually transmitted infection (STI)
  - BXO
PHIMOSIS AND PARAPHIMOSIS

PHIMOSIS

First Line

- Physiologic phimosis:
  - Topical steroids (0.05% betamethasone) may allow atraumatic retraction (3)
  - Parents should be taught to never force back the foreskin but gradually retract it over time.

- Pathologic phimosis:
  - Topical steroid
  - Aggressive retraction can cause worsening of preputial scarring

Paraphimosis:

- Immediate manual reduction should be attempted
- Pain medication (eg, morphine, Demerol) or local anesthesia (lidocaine without epinephrine, infiltration, or penile block) may be necessary

Second Line

- Paraphimosis:
  - Hyaluronidase injection
  - If manual reduction fails, a dorsal slit or incision of constricting band is indicated
- Recurrent paraphimosis may need definitive circumcision to prevent recurrence.

SURGERY/OTHER PROCEDURES

- Phimosis:
  - Preputioplasty (dorsal slit with transverse closure) for patients wanting to maintain foreskin
  - Circumcision is curative; should be generally avoided in children unless for indications such as recurrent UTI, vesicoureteral reflux, or superficial infections
  - Circumcision is contraindicated in newborns with penile deformities (hypospadias, chordee, webbed penis, etc.) as foreskin may be needed for possible reconstructive surgery

- Paraphimosis:
  - Dorsal or ventral slit urgently treats narrowing and preserves the foreskin
  - Immediate circumcision is occasionally necessary

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Compression wraps
- Topical nystatin

REFERENCES

ADDITIONAL READING

CLINICAL/SURGICAL PEARLS

- In most cases physiologic phimosis will resolve. Aggressive retraction of phimosis can cause preputial scarring.
- Manual reduction of paraphimosis should be attempted first prior to surgical intervention.
PNEUMATURIA (GAS IN URINE)
Michael Perrotti, MD

**BASICS**

**DESCRIPTION**
Passage of gas in the urine

**EPIDEMIOLOGY**

**Incidence**
This is a rare disorder.

**RISK FACTORS**
- Diverticular disease
- Other disease of the colon
- Crohn disease
- Advanced age
- Diabetes

**PATHOPHYSIOLOGY**
- Most commonly there is an abnormal connection between the enteric and urinary system secondary to inflammation
- Much less common in gas-producing bacterial urinary tract infection (UTI) (Escherichia coli, Klebsiella pneumoniae) seen most frequently in elderly diabetic females

**ASSOCIATED CONDITIONS**
- Diverticulitis of sigmoid colon
- Colon cancer
- Crohn disease
- Diabetes
- Iatrogenic (radical prostatectomy, radiation)

**GENERAL PREVENTION**
- Colon health
- Prompt treatment of UTI

**DIAGNOSIS**

**HISTORY**
- Pneumaturia
- Dysuria
- Irritative urinary symptoms
- Fecaluria

**PHYSICAL EXAM**
- Depends upon etiology
- May have no significant findings if acute diverticular abscess has resolved
- In emphysematous cystitis there is frequently fever and abdominal tenderness

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urine analysis
- Urine culture
- Complete blood count
- Comprehensive metabolic profile

**Imaging**
- Computed tomography scan identifies air or orally administered contrast in the bladder, colonic, and bladder wall thickening, abscess [1,A]
- Barium enema (definitive: 25%; suggestive: 100%)

**Diagnostic Procedures/Surgery**
- Colonoscopy may directly visualize the fistula, and is essential to inspect the remainder of the colon
- Cystoscopy may visualize the actual fistula, or identify suggestive localized inflammation and edema

**Pathologic Findings**
- Diverticular disease with abscess
- Colon malignancy
- Crohn disease
- Bladder malignancy
- Radiation or surgical induced fistula

**DIFFERENTIAL DIAGNOSIS**
- Emphysematous cystitis
- Emphysematous pyelonephritis
- Unilateral vesical fistula
- Vesical enteric fistula

**TREATMENT**

**GENERAL MEASURES**
- Antibiotic therapy for acute diverticulitis
  - Ciprofloxacin 500 mg PO BID with metronidazole 500 mg PO TID [A]
  - Ampicillin-sulbactam 3 g IV q6h
  - Piperacillin-tazobactam 3.375 g IV q6h
  - Ticarcillin clavulanate 3 g IV q6h
  - Ceftriaxone 1 g IV q24h with metronidazole 500 mg IV q8h

**SURGERY/OTHER PROCEDURES**
- **Emphysematous UTI**
  - Percutaneous management of purulent material and gas
  - Percutaneous nephrostomy placement for emphysematous pyelonephritis
  - Emergent nephrectomy is associated with very high mortality
  - Emergent vesical fistula
  - Enterovesical fistula typically do not close spontaneously
  - The portion of bowel responsible for the fistula is excised in a 1-stage procedure with resection and primary anastomosis
  - Urgent stent placement may be performed preoperatively to allow identification of the ureter intraoperatively
  - Resection of the bladder is rarely necessary
  - A small defect in the bladder can be managed with suture repair, indwelling Foley catheter, and closed suction drain in the pelvis

---
PNEUMATURIA (GAS IN URINE)

ONGOING CARE

PROGNOSIS

- Gas-producing UTI (2)[A]
  - Parenteral antibiotic therapy is successful in the majority of patients with gas limited to bladder
  - Patients with gas in the upper urinary tract are at increased risk of mortality and require percutaneous drainage with parenteral antibiotics
  - Gas in the perinephric space and paranephral tissues are at increased risk of mortality
- Diverticular abscess and enteric vesical fistula
  - Patients have an excellent prognosis after elective resection of the diseased bowel segment
  - In many cases this can be performed laparoscopically (3)[B]

COMPLICATIONS

- Patients with inflammatory disorders such as Crohn may have complex and recurrent fistula
- Patients with fistula following radiation therapy may have impaired healing and experience recurrence

FOLLOW-UP

Patient Monitoring

- Management of associated illness
- Prompt treatment of disease flare

Patient Resources

CODES

ICD9

- 596.1 Intestinovesical fistula
- 599.0 Urinary tract infection, site not specified
- 599.84 Other specified disorders of urethra

ICD10

- N32.1 Vesicointestinal fistula
- N29.0 Urinary tract infection, site not specified
- R39.89 Other symptoms and signs involving the genitourinary system

CLINICAL/SURGICAL PEARLS

- Pneumaturia is the distinct sensation by the patient of passage of air from the urinary tract.
- Pneumaturia should be considered secondary to an enteric vesical fistula unless proven otherwise.
- The CT scan finding of air in the bladder is abnormal and of high diagnostic value in the evaluation of the patient with suspected pneumaturia and is likely to reveal associated pathology.
- The most common cause of pneumaturia is diverticular disease.
POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL DOMINANT

Megan T. Bing, MD
James A. Brown, MD, FACS

ASSOCIATED CONDITIONS
- Abdominal wall hernia
- Cardiac valvular abnormalities
- Colon diverticula
- Hepatic cysts from 29–71%
- Splenic and pancreatic in a small percentage
- Intracranial aneurysms
- Only screen if patient has previous rupture
- Saccular “berry” aneurysm of cerebral arteries in 3–13%
- Pancreatic cysts
- Polycystic liver disease

POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL RECESSIVE
Kymora Scotland, MD, PhD
T. Ernesto Figueroa, MD, FAAP, FACS

DESCRIPTION
A group of inherited disorders involving cystic dilatation of the renal collecting ducts and varying degrees of biliary dysgenesis and portal fibrosis
Formerly known as infantile polycystic kidney disease
An overlap in the spectrum of renal and liver involvement precludes use of the Blyth and Ormond classification (perinatal, neonatal, infantile, and juvenile subtypes)
Best grouped as polycystic disease of newborn and young infant, polycystic disease of childhood, and congenital hepatic fibrosis

EPIDEMIOLOGY
Incidence
Most common inherited cystic renal disease in infancy and childhood
Incidence: 1–2 in 10,000 live births

Prevalence
Commonly diagnosed in perinatal period; can present early in childhood or adolescence
Survival: For patients living to 1 mo: 86% alive at 1 yr, 67% alive at 15 yr

RISK FACTORS
Definite risk factor: Heterozygous parents
Liver function tests (usually normal)
Coagulation profile
CBC (exclude anemia, hypersplenism)
Electrolytes, blood chemistry, urine analysis, urine culture

PHYSICAL EXAM
– Potter phenotype, pallor
– Polydipsia, polyuria, fatigue, unexplained fever, HTN, respiratory rate, temperature
– For older patient, may suggest evolution of disease

DIAGNOSTIC TESTS & INTERPRETATION
– Normal parents with a normal renal US suggests recessive disease

ASSOCIATED CONDITIONS
– Potter syndrome
– Ectopia cordis
– Potter–Ferguson syndrome

DIAGNOSIS
History
– Age of the patient:
  – Other cystic renal disorders rarely present in the pediatric population:
    – Younger, more exploratory and renal issues
  – Older, more hepatobiliary issues
  – 1/3 are diagnosed before age 1; 1/3 between age 1 and 20 yr; and 1/3 beyond 20 yr
– Present care
  – Characteristic changes on prenatal US after week 30, abnormal ureter growth measurements, maternal w fetoprotein levels, amniocentesis results, history of stillbirth
– Birth history:
  – Delivery: difficult delivery suggests possible flank or abdominal mass
  – Family history:
    – Normal patients with a normal renal US suggests recessive disease
    – Medical history:
      – For other patient, may suggest evolution of disease

Diagnosis
– Potter phenotype
– Polydipsia, polyuria, fatigue, unexplained fever
– Hepatosplenomegaly
– Difficulty breathing and feeding
– Infant with hypotonia
– Abnormal US

DIAGNOSIS TESTS & INTERPRETATION
– Echocardiography
– Abdominal ultrasonography
– MRI, CT scan

MAJOR COMPLICATIONS
– Progressive renal insufficiency
– Renal failure

DIAGNOSTIC PROCEDURES/SURGERY
– Nephrectomy
– Liver biopsy

DIAGNOSTIC TESTING
– Imaging
  – Ultrasound: Enlarged kidneys, oligohydramnios, normal liver, no bladder filling
  – CT scan: Enlarged liver, normal renal US
– CT may be used in confusing cases: More sensitive to inhomogeneity of cysts
– MRI may be used in confusing cases: More sensitive to inhomogeneity of cysts

IMAGING
– Ultrasound
– MRI
– CT
– Angiography
– Renal biopsy
– Liver biopsy

DIFFERENTIAL DIAGNOSIS
– Autosomal dominant polycystic kidney disease (ADPKD)
– Medullary cystic disease
– Meckel–Gruber syndrome
– Autosomal recessive polycystic kidney disease (ARPKD)

IMAGING
– Ultrasound
– MRI
– CT
– Angiography
– Renal biopsy
– Liver biopsy

DIFFERENTIAL DIAGNOSIS
– Autosomal dominant polycystic kidney disease (ADPKD)
– Medullary cystic disease
– Meckel–Gruber syndrome
– Autosomal recessive polycystic kidney disease (ARPKD)
TREATMENT

GENERAL MEASURES
- No specific therapy for ARPKD. Treatments are supportive.
- Pulmonary issues 1st priority initially; survival better with advances in perinatology.
- Goals: Delay progression to renal failure, liver failure, and portal HTN.
- Avoid nephrotoxic medications.
- Social support and intensive care.

MEDICATION

First Line
- Thiazides to help urine-concentrating defect.
- Treatment of renal osteodystrophy with vitamin D and phosphate binders.
- Recombinant human erythropoietin.
- Growth hormone treatment.

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Prophylactic bilateral nephrectomy and peritoneal dialysis catheter (significant pulmonary distress).
- Unilateral nephrectomy (improve feedings; help with breathing).
- Gastrostomy tube placement (improve feedings).
- Splanchnicectomy; or pericaval short procedures (portal HTN).
- Renal transplantation (EJSD).
- Liver transplantation (hepatic failure).
- Progressive liver fibrosis with portal hypertension.

ADDITIONAL TREATMENT

Radiation Therapy
- N/A

Additional Therapies
- Adequate hydration.
- Correct acid-base and electrolyte abnormalities.
- Aggressive HTN control.
- Peritoneal dialysis.
- Enteral feedings.
- Advanced pulmonary support as required.

Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS
- Mortal.
- Abnormal prenatal US (polysplenia, enlarged rib margins, absent egg in bladder, severe IUGR, gestational age <33 wks).
- Neonates: If present at birth, the usual clinical course is death. Patients have feeding intolerance, respiratory distress.
- Infants: Palpable flank masses, abdominal mass, Potter phenotype, GI bleed, hepatosplenomegaly, polyuria, polydipsia, polyuria, HTN, nonspecific GI complaints, edema, growth retardation, fatigue, infection. Will eventually develop renal failure and HTN.
- All patients with ARPKD have liver involvement.
- Those with severe ARPKD have mild congenital hepatic fibrosis and those with severe congenital hepatic fibrosis have mild ARPKD.

COMPLICATIONS
- Renal: Renal failure (concentrating defect with polydipsia and polyuria), HTN, anemia, occasional metabolic acidosis, hyperuricemia, osteodystrophy, growth failure, UTI.
- Hepatobiliary: Hepatoplenomegaly, bleeding esophageal varices, portal thrombosis, cholangitis.
- Pulmonary: Respiratory failure, portal HTN.
- Complications: GI feeding intolerance, failure to thrive.

FOLLOW-UP

Patient Monitoring
- Progressive renal failure in most patients requiring ongoing renal assessments.
- Blood pressure.
- Liver functions and ultrasound at least annually.
- Overall assessment of growth and nutritional status.
- Parental counseling is critical as there is a 1 in 4 chance of another child having the disease.

Patient Resources

Clinical/Surgical Pearls
- Renal and liver involvement is typical.
- Often fatal if present at birth.
- Treatments are supportive; no specific therapy.
**Polyhydramnios/Oligohydramnios**

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

**BASICS**

**DESCRIPTION**
- Oligohydramnios is defined as an abnormally low amniotic fluid (AF) volume.
- Associated with increased fetal morbidity and mortality
- Polyhydramnios is defined as an abnormally high AF volume:
  - Up to 25% of neonates will have a congenital anomaly
  - Associated with increase in aneuploidy, congenital malformations, prematurity, and perinatal death
- These conditions are diagnosed using prenatal US with strict criterion described below

**EPIDEMIOLOGY**

**Incidence**
- Oligohydramnios in 3–5% of pregnancies (1)
- Polyhydramnios in 1–3% of pregnancies (1)
- Usually discovered in 2nd trimester with 40% normal by term

**Prevalence**
- N/A

**RISK FACTORS**
- **Oligohydramnios**
  - Prerenal: Placental insufficiency, umbilical cord
  - Spontaneous/idiopathic
  - Iatrogenic: Amniocentesis
- **Polyhydramnios**
  - Maternal diabetes
  - Nonimmune hydrops fetalis
  - GI obstruction (esophageal atresia, duodenal atresia)
  - Neural tube defects
  - Anencephaly
  - Potter syndrome:
    - Pulmonary hypoplasia, limb abnormalities
    - Multicystic dysplastic kidney or prune-belly syndrome
    - Oligohydramnios: Decreased maternal fundal height
    - Polyhydramnios: Increased maternal fundal height

**ASSOCIATED CONDITIONS**
- **Polyhydramnios:**
  - Pulmonary hypoplasia: Correlated with fetal outcome and main cause of fetal death
  - Intrauterine growth restriction
  - Potter facies with severe oligohydramnios
  - Better outcome if presents in 3rd trimester vs. 2nd trimester (3)
  - Better outcome if cause is PROM vs. congenital anomaly (3)
- **Causes of polyhydramnios**
  - Obligatory: >60%
  - Better outcomes:
    - Maternal causes: ∼15%
    - Maternal diabetes
    - Infections: Syphilis, rubella, TORCH, toxoplasmosis, parvovirus, RH immunization
    - Drug abuse: Polyhydramnios in ∼25–30% of drug-addicted women. Leads to decreased neurologic function of fetus and decreased swallowing
  - Fetal causes:
    - Reduced fetal swallowing: Maternal drug use, fetal neurologic anomalies, aneuploidy
    - GI anomalies: T-E fistula, choanal atresia, facial cleft, esophageal atresia, imperforate anus
    - Cardiac failure with diuresis

**DIAGNOSTIC TESTS & INTERPRETATION**

**PHYSICAL EXAM**
- **Polyhydramnios:**
  - Increased maternal fundal height
  - Pulmonary hypoplasia: Correlated with fetal outcome and main cause of fetal death

**LABORATORY EXAM**
- **Polyhydramnios:**
  - Increased maternal weight
  - Maternal infectious exposure
- **Oligohydramnios:**
  - Poor weight gain
  - Medication history

**GENERAL PREVENTION**
- **Polyhydramnios:**
  - Avoid known medications (NSAIDs, etc.)
  - Avoid maternal dehydration
- **Oligohydramnios:**
  - Prevention of infections transmissible from mother to fetus
  - Avoid drug abuse

**DIAGNOSIS**

**HISTORY**
- **Polyhydramnios:**
  - Increased maternal weight
  - Maternal drug use
  - Maternal infectious exposure
- **Oligohydramnios:**
  - Poor weight gain
  - Medication history

**PHYSICAL EXAM**
- **Polyhydramnios:**
  - Increased maternal fundal height
  - Pulmonary hypoplasia: Correlated with fetal outcome and main cause of fetal death

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- **Polyhydramnios:**
  - Maternal testing for glucose, autoantibodies, TORCH screen, parvovirus, fetal karotype
- **Oligohydramnios:**
  - General: Fetal karotype, pulmonary maturity, maternal autoantibodies (lupus, antiphospholipid, anticonvulsant)
  - Renal: Maternal urinary electrolytes
  - Better outcome associated with β2-microglobulin, α2-microglobulin, and retinal-binding protein

**Imaging**
- US measurements of AF volumes are very operator-dependent and very variable (4)
- No perfect means to determine actual volume, but several surrogate markers are used:
  - Maximum vertical pocket: Polyhydramnios >7 cm, oligohydramnios <1 cm
  - AFI: Sum of largest volumes from each of 4 placental quadrants:
    - Oligohydramnios <5 cm, polyhydramnios >25 cm
  - Fetal MRI increasingly used for better anatomic detail
Differential Diagnosis

- Polyhydramnios
  - Premature rupture of membranes (PROM)
  - Maternal: Rh isoimmunization, neural tube defects, maternal diabetes, maternal HTN, autoimmune disorders, drugs (NSAIDs, ACE inhibitors)
  - Internal: Renal dysplasia, renal agenesis
  - Obstetric: Polyhydramnios, pruritis, blunt trauma, ureteral obstruction, bilateral hydronephrosis
  - Prolonged gestation can lead to polyhydramnios late in pregnancy

- Oligohydramnios
  - Idiopathic — 60%
  - Better outcomes
    - Maternal causes: ~15%
    - Maternal diabetes
    - Infections: Syphilis, rubella, MRSA
    - Drug abuse: Polyhydramnios in ~25–30% of drug-addicted women. Leads to decreased neurologic function of fetus and decreased swallowing
    - Placental chorangioma or arteriovenous fistula
    - Fetal causes:
      - Reduced fetal swallowing: Maternal drug use, anemia, renal tube defects, muscular dystrophy syndromes, aneuploidy
      - GI anomalies: Tetralogy of Fallot, intestinal atresia, facial defects, esophageal atresia, imperforate anus, gastroschisis, duodenal atresia/stenosis, cleft, esophageal atresia, imperforate anus, congenital anomalies (3)
      - Heart failure: Congestive heart failure, severe anemia
      - Karyotype anomalies: Trisomy 21, etc.
      - Multiple malformations: Rh disease, severe anemia, infections in mother (e.g., pneumonia, CMV), twin–twin transfusion syndrome, maternal hypertension, disorders of glycosylation
      - Other: Sclerocystic teratoma, skeletal dysplasia, thrombocytopenia

Prognosis

- Polyhydramnios: If idiopathic, the prognosis is usually good
- Oligohydramnios:
  - With normal agenesis, mortality rate is 100%
  - Fetal outcomes correlated to degree of pulmonary hypoplasia
  - Mild forms of obstructive uropathy may cause renal insufficiency
  - Better prognosis with presentation in 3rd vs. 2nd trimester (c)
  - Better prognosis with PROM as cause vs. congenital anomalies (d)

Complications

- Polyhydramnios can cause increased prematurity labor
- Oligohydramnios can cause fetal distress before or during labor and severe respiratory distress and pneumonia due to pulmonary hypoplasia

Treatment

General Measures

- Polyhydramnios:
  - US every 3–4 wk
  - Follow pregnancy to 38 wk
  - Monitor for UTI
  - Amnioinfusion
- Oligohydramnios:
  - US every 3–4 wk for fetal viability and IUP

Follow-Up

- Close monitoring by prenatal sonography

Prevention

- Early delivery with steroids for severe oligohydramnios and pulmonary hypoplasia
- Consider early delivery with steroids for oligohydramnios due to bladder outlet obstruction

ADDITIONAL READING

ICD9

- 657.00 Oligohydramnios, unspecified as to episode of care or not applicable
- 658.00 Polyhydramnios, unspecified as to episode of care or not applicable
- 761.2 Oligohydramnios affecting fetus or newborn

ICD10

- O41.00X0 Oligohydramnios, unspecified trimester
- O40.9XX0 Polyhydramnios, unspecified trimester
- A21.9000 Oligohydramnios, unspecified trimester, not applicable or unspecified
- A01.00X0 Polyhydramnios, unspecified trimester, not applicable or unspecified
- P01.2 Newborn (suspected to be) affected by oligohydramnios

Clinical/Surgical Pearls

- If amniotic fluid (AF) levels are normal, the fetus is very likely to have adequate urine production even with bilateral hydramnios.
- In cases of intervention with vesicoamniotic shunt, it is controversial.
- Idiopathic polyhydramnios has good outcomes.
POLYOMA VIRUS (BK, JC), UROLOGIC CONSIDERATIONS

Nathan Roberts, MD
Patrick J. Shenot, MD, FACS

DESCRIPTION

- JC and BK viruses are 2 of 10 different human polyoma viruses
- Small DNA viruses in the papovavidae family
- JC and BK viruses named after 1st patients the viruses were isolated from in 1971
- These viruses typically manifest clinical sequelae only in immunocompromised hosts
- BK virus has a tropism for genitourinary epithelium
  - Clinical manifestations: Hemorrhagic cystitis (HC), ureteral stenosis, nephropathy, and rare GU-associated malignancies

EPIDEMIOLOGY

Incidence

- Prevalence
  - BK virus has an 82–99% seroprevalence in adults of the United States, Italy, and Australia
  - 50% at 2 yr of age, 90% at 10 yr of age
  - JC virus has a 38–81% seroprevalence in same regions
  - Clinically manifest only in immunocompromised subjects
- Universal serostatus due to BK virus infection among allograft recipients is approximately 4%
- BK-induced nephropathy: 1–10% of transplants

Hemorrhagic cystitis

- Reported to cause hemorrhagic cystitis in 5.7–7.7% of bone marrow transplant recipients

ASSOCIATED CONDITIONS

- Immunocompromised host
  - Degree of immunosuppression
  - Transplant recipients
    - Solid organ (especially kidney), stem cell transplants
    - HIV/AIDS
  - Prophylaxis toward hemorrhagic cystitis
  - Autoimmune disorders requiring immunosuppression
  - Multiple sclerosis

Genetics

- Small nonenveloped (icosahedral particles of 40–45-nm diameter with a nonenveloped, circular double-stranded DNA genome
- Polyoma viruses encode 6 proteins
  - 3 structural capsid proteins
  - 3 noncapid regulatory proteins
  - Large and small T antigen (cell immortalization and latency), and agnoprotein (assembly of viral particles)
  - Proteins interact with cellular target proteins and impair pathways involved with cell cycle and DNA repair

PATHOPHYSIOLOGY

- Route of transmission is unknown but seems to occur early in life most likely seak spharyngeal exposure (1,2)
- Hyperplasia of subclinical infection leads to viremia that seeds the kidneys
- Pathology is postulated to occur from reactivation of latent infection and not reactivation
- Immunocompromise/inflammation syndrome
  - Dominant inflammatory response to BK virus antigen followed by brisk recovery of the cellular immune response
    - Seen in BKV-associated hemorrhagic cystitis
      - After allogeneic stem cell transplantation
  - Cytopathic inflammatory polyomavirus pathology
    - High-level virus replication and a significant inflammatory response due to lytic viral T-lymphocytic necrosis, with infiltration of granulocytes and lymphocytes
    - Dominant inflammatory response to abundant polyoma virus antigen followed by brisk recovery of the cellular immune response
    - Seen in BKV-associated nephropathy in kidney allografts
- Oncogenic polyomavirus pathology
  - Early viral gene expression activating host cells but without sufficient late gene expression to cause rapid host cell lysis
  - Seen in rare BKV-associated urethral and renal tubular cancers
  - There is conflicting evidence of BK virus involvement in these tumors
- Hemorrhagic cystitis
  - Another theory suggests 3 phases
    - Conditioning regimen for stem cell transplant damages the bladder mucosa providing environment for virus replication
    - Viral replication unchecked in the absence of functional immunity
    - Further damage to the bladder mucosa with immune reconstitution and return of anti-BK immunity
- Immuno-reconstitution inflammatory syndrome
  - Due to denervation of transplanted kidney, patient may not present with pain

ASSOCIATED CONDITIONS

- BK virus has a tropism for genitourinary epithelium
  - Kidney transplant recipients
    - Tubulointerstitial nephritis
    - Ureteral stenosis
  - Stem cell transplant recipients
    - Hemorrhagic cystis
    - JC virus has a tropism for neural tissue
    - Causes progressive multifocal leukoencephalopathy
    - Not as common, but JC can also be related to genitourinary manifestations like BK virus and vice versa

ASSOCIATED CONDITIONS

- Route of transmission is unknown so difficult to prevent
- Competent immune system will prevent clinical sequelae

DIAGNOSIS

HISTORY

- Hemorrhagic cystitis
  - From pink colored urine to clot retention
  - Pt can also have bladder pain
  - Pt may have UTI
  - BK virus nephropathy
    - Typically occurs 10–13 mo after transplant
    - Often asymptomatic
    - May have hematuria
    - May have decreased urine output
    - Transplanted ureteral stricture (3)
      - Typically occurs 2–4 mo after transplant
    - Often asymptomatic
    - May have decreased urine output

PHYSICAL EXAM

- Hemorrhagic cystitis
  - May present with palpable bladder if in clot retention
  - BK virus nephropathy
    - No significant findings on exam
  - Universal stenosis of kidney transplant
    - May have no significant findings
    - Pelvic mass bulge from transplant hydronephrosis
    - Due to denervation of transplanted kidney, patient may not present with pain

DIAGNOSTIC TESTS & INTERPRETATION

LAB

- Urine culture mostly used in research setting
- Takes weeks to months to grow
- Unreliable findings
- Detects virus shedding
- Characteristic finding is an enlarged nucleus with a single large basophilic intranuclear inclusion (“decoy cells”)
- Does not distinguish between various types of polyoma virus
- BK virus quantitative PCR
  - Correlates with BK virus associated nephropathy
  - Can be positive in normal controls, elderly patients and HIV-infected patients without clinical manifestations
  - Difficult to assess clinical significance
- Plasma quantitative PCR
- Hemorrhagic cystitis
  - Urine positive for blood/WBCs
  - BK virus nephropathy
  - Elevated creatinine
  - Urinalysis
    - Pyuria, hematuria, and/or cellular casts of renal tubular cells and inflammatory cells
    - May have decreased urine output
  - Transplant ureteral stricture
    - Can have elevated creatinine

IMAGING

- Hemorrhagic cystitis
  - Ultrason or CT scan show bladder thickening
  - Can show clot retention
  - Transplanted ureteral stricture
  - Hydronephrosis seen on renal ultrasound, CT or MRI
  - Pelvic mass bulge from transplant hydronephrosis
  - May present with pain
POLYOMA VIRUS (BK, JC), UROLOGIC CONSIDERATIONS

Diagnostic Procedures/Surgery
- Hemorrhagic cystitis
  - Cystoscopy can show evidence of obstructive bleeding
- BK virus nephropathy
  - Renal biopsy
  - Most often percutaneous approach
  - Histopathology results listed below
  - Can also use Immunohistologic or in situ hybridization evidence of virally infected cells to make diagnosis
  - Strongly positive using an SV40 immunohistochemical stain

Pathologic Findings
- BK Virus nephropathy
  - Usually infects tubule epithelial cells
  - Adenoviruses, Herpesviridae, and Chromatin clumping of infected cells
  - Interstitial mononuclear or polymorphonuclear cell infiltrates in the areas of tubular damage
  - Tubular injury with tubular cell apoptosis
  - Intravascular bafilomycin viral inclusions with a surrounding halo
- Not pathognomonic for BK virus
- CMV has cytopathic inclusion
- HSV has both intranuclear and cytoplasmic inclusions

Differential Diagnosis
- Hemorrhagic cystitis
  - Medication related (high-dose cyclophosphamide)
    - Often occurs within 7–14 days
  - Adenovirus related
  - Radiation induced
  - Infectious source
  - Trauma
    - Possibly from urethral catheter placement
- BK virus nephropathy
  - Cellular rejection
  - Transplant ureteral stenosis
  - Surgical technique, ischemia of distal ureter
    - Typically occurs in 7–10 days

TREATMENT
GENERAL MEASURES
- Reduction of immunosuppression if possible (4)
  - Often most effective strategy

MEDICATION
First Line
- Quinolones antibiotic (ciprofloxacin, etc.)
  - Suggested for prophylactic role
- Intravenous Immunoglobulin
  - Can be used in hypogammaglobulinemic patients
- Leflunomide: Antiviral activity

Second Line
- Intravenous or intravenous clindamycin
  - Nucleotide analog of cytosine
  - Active against DNA viruses
- Anecdotical evidence for use against polyoma viruses
- Highly nephrotoxic

OTHER PROCEDURES
- Hemorrhagic cystitis
  - Cystoscopic fulguration (electro cautery or laser)
  - Conjugated estrogens: Act by stabilization of microvasculature
  - Intravesical instillation of formalin
    - 60%–1% instilled for 10–20 min
    - May lead to renal failure due to precipitation and obstruction of upper tracts
    - E-aminocaproic acid
      - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
      - Given orally, peripherally, or intravesically
      - Patients can form hard clots that are difficult to flush from the bladder
- Intravesical instillation of prostaglandin
  - PGF2a. May encourage platelet aggregation and induce vasoconstriction
  - PGF2a 0.75 mg in 200 mL of normal saline and left indwelling
  - May cause bladder spasms
    - Painful and needs to be done with general anesthesia
- Intravesical instillation of formalin
  - 40% formoldehyde
    - Hydrolizes proteins and coagulates tissue on superficial level
- Intravesical instillation of silver nitrate
  - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
    - Can result in small contracted bladder
- Intravesical instillation of cadaverine

SPECIAL WEBSITES
- Hemorrhagic cystitis
  - Cystoscopic instillation (electro cautery or laser)
  - Conjugated estrogens: Act by stabilization of microvasculature
  - Intravesical instillation of formalin
    - 40% formoldehyde
    - Hydrolizes proteins and coagulates tissue on superficial level
  - Intravesical instillation of prostaglandin
    - PGF2a. May encourage platelet aggregation and induce vasoconstriction
    - PGF2a 0.75 mg in 200 mL of normal saline and left indwelling
    - May cause bladder spasms
    - Painful and needs to be done with general anesthesia
- Intravesical instillation of formalin
  - 40% formoldehyde
    - Hydrolizes proteins and coagulates tissue on superficial level
- Intravesical instillation of silver nitrate
  - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
    - Can result in small contracted bladder

SURGERY/OTHER PROCEDURES
- Hemorrhagic cystitis
  - Cystoscopic instillation (electro cautery or laser)
  - Selective embolization
  - Vescical or internal iliac artery
- BK virus Nephropathy
  - Kidney re-transplant
  - Limited information for outcomes
  - Recommended patients have absence of BK replication prior to re-transplantation
  - Transplant ureteral stenosis
  - Decompression of the transplanted kidney
  - Periureteral nephroptosis tube
  - Urinary stent placement
  - Surgical excision of stenotic segment

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Hemorrhagic cystitis
  - Hyperbaric oxygen: Promotes healing of hypoxic tissues and aid in angiogenesis

COMPLEMENTARY & ALTERNATIVE THERAPIES
N/A

ONGOING CARE
PROGNOSIS
- Hemorrhagic cystitis: Dramatic in presentation but usually resolves spontaneously within 2 wk with supportive care
- BK virus nephropathy: Graft failure in 15–50%

FOLLOW-UP
Patient Monitoring
BK virus nephropathy: After transplant same recommended periodic monitoring for viremia

Patient Resources
N/A

REFERENCES

ADDITIONAL READING

CLINICAL/SURGICAL PEARLS
Polyoma virus will only have clinical sequelae in immunocompromised patients.
POSTERIOR URETHRAL VALVES

Steve J. Hodges, MD
Anthony Atala, MD

**DESCRIPTION**

- Congenital obstruction of the posterior urethra that can cause variable degrees of dysfunction of all segments of the urinary tract, including the bladder, ureters, and kidneys.
- Urinary tract dysfunction can include:
  - Functional bladder disorders including increased bladder wall thickness, fibrosis, and hypercontractility that may progress to incontinence and poor function
  - The bladder changes may affect the upper tracts by transmitting high pressures to the renal parenchyma, causing deterioration of renal function
  - Patients may have congenital renal dysplasia

**Epidemiology**

- Incidence/Prevalence
  - The prevalence is 1:2,400–1:8,000
  - 1 in 4,000–7,500 live male births
  - Congenital disorder
  - Urinary tract dysfunction can include:
    - Type III: Transverse membrane in the posterior urethra
    - Type II: Folds extending from the verumontanum
    - Type I: Folds that extend distally from the posterior urethra

- Risk Factors
  - Only affects males
  - No racial predilection

- Diagnosis
  - High risk of end-stage renal disease in urethral valve patients

**Associated Conditions**

- Renal dysplasia
- Bladder diverticula
- Acholuria
- Urine extravasation
- Vesicoureteral reflux
- Anal stenosis
- Hydroureteronephrosis
- VURD

**Genetics**

- This disorder is usually sporadic
- Cases have been seen in twins and siblings suggesting a poorly understood genetic component

**Pathophysiology**

- Congenital muscular membrane (folds/lisae) in the posterior urethra
- Hugh H. Young Classification (1919)
  - Type I: Folds that extend distally from the verumontanum to divide into 2 membranes that attach to the anterolateral wall, most common variant (95%)
  - Type II: Folds extending from the verumontanum to the bladder neck superiorly, not clinically obstructing, only of historical significance
  - Type III: Transverse membrane in the posterior urethra, has a central aperture, located distal to verumontanum, rare (0.4%)

**Associated Conditions**

- Renal dysplasia
- Bladder diverticula
- Acholuria
- Urine extravasation
- Vesicoureteral reflux
- Anal stenosis
- Hydroureteronephrosis
- VURD

**General Prevention**

- No known methods of prevention

**Differential Diagnosis**

- Anterior urethral valves
- Bilateral urethral obstruction
- Congenital urethral palse
- Congenital urethral stenosis (Cobb collar)
- Megacystis-megaureter
- Megacystis-megaureter
- Multicystic dysplastic kidney
- Neurogenic bladder
- Neurogenic neurogenic bladder (Herman syndrome)
- Phallic caliciform
- Normal anatomic finding
- Represents this folds of mucosa that extend from the verumontanum in the prostatic urethra to the membranous urethra
- Prune belly syndrome
- Urethral atresia

**Diagnostic Tests & Interpretation**

- Lab
  - Urinalysis and urine culture
  - Serum electrolytes, BUN, and Cr
  - Cr has early prognostic value
  - Elevated Cr in 1st few days of life (after the 1st 5 days) indicates renal dysfunction and poor prognosis
  - Cr > 1 at the end of the 1st yr of life predicts of eventual ESRD

- Imaging
  - Renal/bladder US
  - Assesses for hydroureteronephrosis, corticomedullary differentiation, echogenicity, signs of renal dysplasia, thickness of renal parenchyma and bladder wall
  - VCUG
  - Diagnoses urethral valves, detects vesicoureteral reflux and bladder trabeculation diverticula
  - Shows dilated posterior urethra, trabeculated bladder, vesicoureteral reflux, perhaps azotemia
  - Hydroureteronephrosis
  - DMSA Renogram
  - After 6 wk of life may be used to evaluate renal function, dysplasia

- Diagnostic Procedures/Surgery

- Antenatal US: Bilateral hydroureteronephrosis (± oligohydramnios, the earlier the diagnosis the worse the prognosis)
- Postnatal
  - Urinalysis and urine culture
  - Serum electrolytes, BUN, and Cr
  - Cr has early prognostic value
  - Elevated Cr in 1st few days of life (after the 1st 5 days) indicates renal dysfunction and poor prognosis
  - Cr > 1 at the end of the 1st yr of life predictive of eventual ESRD

- Pathologic Findings

- Isolated

- Associated with:
  - Antenatal US: Bilateral hydroureteronephrosis (± oligohydramnios, the earlier the diagnosis the worse the prognosis)

- Postnatal
  - Urinalysis and urine culture
  - Serum electrolytes, BUN, and Cr
  - Cr has early prognostic value
  - Elevated Cr in 1st few days of life (after the 1st 5 days) indicates renal dysfunction and poor prognosis
  - Cr > 1 at the end of the 1st yr of life predictive of eventual ESRD

- Pathologic Findings

- Isolated

- Associated with:
  - Hydroureteronephrosis
  - Vesicoureteral reflux
  - Anal stenosis
  - Neurogenic bladder
  - Neurogenic neurogenic bladder (Herman syndrome)
  - Phallic caliciform
  - Normal anatomic finding
  - Represents this folds of mucosa that extend from the verumontanum in the prostatic urethra to the membranous urethra
  - Prune belly syndrome
  - Urethral atresia

- Pathologic Findings

- Isolated

- Associated with:
  - Hydroureteronephrosis
  - Vesicoureteral reflux
  - Anal stenosis
  - Neurogenic bladder
  - Neurogenic neurogenic bladder (Herman syndrome)
  - Phallic caliciform
  - Normal anatomic finding
  - Represents this folds of mucosa that extend from the verumontanum in the prostatic urethra to the membranous urethra
  - Prune belly syndrome
  - Urethral atresia
POSTERIOR URETHRAL VALVES

TREATMENT

GENERAL MEASURES
- Place urethral catheter immediately after birth to drain the bladder (1)
- Measure daily weights, I/O's (fluid balance), routine vital signs
- Fluid and electrolytes as needed

MEDICATION
First Line
- Prophylactic antibiotics
  - <2 mo age: Amoxicillin 20 mg/kg/d
  - ≥2 mo of age: Trimethoprim-sulfamethoxazole 2 mg/kg/d (concentrates in urine), intravenous is an alternative
- Anticholinergics for bladder dysfunction

SURGERY/OTHER PROCEDURES
- Transurethral ablation of valves is possible in 80% of neonates
- Cutaneous vesicostomy in children too small for endoscopy (usually <2,000 g)
- Bilateral cutaneous pyelostomies of mostly historical significance, but may be used in extreme cases

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Adjuvant Therapies
- Prenatal surgical intervention remains investigational
  - Associated with risk of fetal and maternal morbidity, long-term renal benefit proven
- In children with persistent worsening renal function and hydronephrosis following valve ablation may require upper tract diversion if possible to salvage renal function
- Persistent vesicoureteral reflux following valve ablation may require ureteral reimplantation
- Low compliance fibrotic bladder or myogenic failure (valve bladder) may require enterocystoplasty and/or clean intermittent catheterization (CIC)

Complications
- Follow-up for observation of progress of renal function, as high risk of ESRD
  - Usual late or difficult toilet training, treat voiding dysfunction, incontinence
  - Patients need serial electrolyte and Cr measurements, US evaluations, VCUG following ablation to monitor success of surgery, resolution of reflux
  - UDS for bladder function
  - Prophylactic antibiotics as needed

Patient Resources
http://www.chop.edu/healthinfo/posterior-urethral-valves-puv.html

ONGOING CARE

PROGNOSIS
- Depends on the amount of congenital renal dysplasia, vesicoureteral reflux, bladder function
- Incontinence and later ESRD correlated
- Cr >1 mg/dL at the end of the 1st yr of life correlated with ESRD
- Sexual function and fertility seems to be normal in most patients

FOLLOW-UP
Patient Monitoring
- Follow-up for observation of progress of renal function, as high risk of ESRD
  - Usual late or difficult toilet training, treat voiding dysfunction, incontinence
  - Patients need serial electrolyte and Cr measurements, US evaluations, VCUG following ablation to monitor success of surgery, resolution of reflux
  - UDS for bladder function
  - Prophylactic antibiotics as needed

- Urethra, Obstruction
- VURD Syndrome

CODES
ICD9
- 599.69 Urinary obstruction, not elsewhere classified
- 753.8 Other specified anomalies of bladder and urethra
- 753.15 Renal dysplasia

ICD10
- N13.8 Other obstructive and reflux uropathy
- O61.4 Renal dysplasia
- O64.79 Other congenital malformations of bladder and urethra

CLINICAL/SURGICAL PEARLS
- No benefit to early delivery as children with pulmonary hypoplasia also have severe renal dysplasia
- Select centers offer prenatal interventions with dubious efficacy
- Poor kidney function at presentation is associated with worse renal prognosis.
POSTOBSTRUCTIVE DIURESIS
John J. Pahira, MD

PATHOPHYSIOLOGY
- Retained urea, sodium, and water; impaired sodium reabsorption and concentrating ability of the renal tubule; and circulating hormones all contribute:
  - Increased sodium, potassium, and magnesium losses result in increased water excretion
  - Accumulated urea acts as an osmotic agent, bringing fluid with it as it is cleared, thereby increasing diuresis
  - Impaired concentrating ability of the renal tubule leads to continuing fluid losses and hypovolemia
- ANP, which causes vasodilation, natriuresis, and diuresis, has been found to be elevated in patients with ureteral obstruction (1)[B]

ASSOCIATED CONDITIONS
- BPH
- Malignancies (bladder or prostate cancer)
- Urolithiasis
- Any cause of chronic obstruction with hydronephrosis

GENERAL PREVENTION
Treat and repair the cause of obstruction to prevent recurrence

DIAGNOSIS
HISTORY
- Obstruction:
  - Asymptomatic but often associated with flank pain radiating to groin and/or ipsilateral thigh, nausea, vomiting, fevers, chills
  - Resulting uremia may cause mental status changes, tremors, and GI bleeding (2)[A]
- Diuresis:
  - Increase in urine output out of proportion to fluid intake, usually >200 mL/hr
- Chronic obstruction:
  - Weight gain, malaise, fatigue, shortness of breath
  - Abdominal mass, suprapubic tenderness, flank tenderness

PHYSICAL EXAM
- Chronic obstruction:
  - Pulmonary congestion, pitting edema of lower extremities, HTN
- Acute obstruction:
  - Abdominal mass, suprapubic tenderness, flank tenderness

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC, urine culture and sensitivity:
  - Infection in the setting of obstruction requires emergent evaluation and treatment
- SMA-7
  - BUN and creatinine are typically elevated and are monitored after relief of obstruction
  - POD may cause profound hypokalemia
- Magnesium and calcium may need preplacement
- Urine osmolality:
  - Evaluate the kidney’s ability to concentrate urine; typically impaired concentrating ability

Imaging
- US is the screening test of choice to evaluate obstruction
  - Without hydronephrosis, diagnosis of POD should be questioned

Diagnostic Procedures/Surgery
Monitor urine output
Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Causes of polyuria:
  - Medications:
    - Lithium carbonate, methoxyflurane, demethylchlortetracycline, amphotericin B, mannitol, glycerol, diuretics, ethanol, opiate antagonist, phenytoin
  - Diabetes insipidus
  - Diabetes mellitus
  - Renal disease: Diuretic phase of ATN
  - Physiologic diuresis from fluid excess
POSTOBSTRUCTIVE DIURESIS

TREATMENT

GENERAL MEASURES
• After the obstruction is relieved, admit the patient to the hospital to closely monitor hemodynamic status and electrolytes, I&O and daily weights
• Monitor urine output q2h and replace with oral fluids if oral intake is not keeping up then with IV fluids (0.5–1.0 mL of ½ NS/mL of urine output) in addition to PO fluids:
  – If urine output decreases to <250 mL/hr replace fluids volume <50 mL of the urine output per hour. Adjust accordingly as the diuresis resolves
• If patient at risk of congestive heart failure or has pulmonary edema, replace at a slower rate
• Check serum sodium and potassium q6–12h and replace as needed
• Follow BUN and creatinine values until normal:
  – Replace sodium, potassium, magnesium, and bicarbonate as needed

ONGOING CARE

PROGNOSIS
• The rate of recovery is largely determined by the duration and severity of obstructive disease.
• Extent of recovery can be estimated by the improvement in renal function within 7–14 days after the obstruction has been relieved:
  – Some patients may require short-term treatment with dialysis, until their renal function recovers.

COMPLICATIONS
• Uremic death
• Hypovolemic circulatory collapse
• Bladder mucosal bleeding secondary to vein rupture resulting from rapid bladder decompression
• Arrhythmia secondary to electrolyte abnormalities

FOLLOW-UP

Patient Monitoring
Serial (weekly to monthly) renal function testing (creatinine, BUN), renal US imaging if lab values do not return to normal range

Patient Resources
N/A

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
Management of any renal insufficiency

CLINICAL/SURGICAL PEARLS

Maintain a high degree of suspicion for the potential for postobstructive diuresis when relieving chronic obstruction of the urinary tract.
• Diuresis is usually self-limiting and typically lasts <48 hr.

ALERT
• If there is persistent hydronephrosis, consider persistent obstruction of ureter(s) above the level of the bladder or a nonfunctioning stent/pseudoaneurysm tube (36A).

PREGNANCY, UROLITHIASIS

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

### BASICS

- **DESCRIPTION**
  - The presence of calculi in the urinary tract during pregnancy can lead to severe risks and problems in management.
  - Urolithiasis is the most common cause of nondystrophic abdominal pain that requires hospitalization among pregnant patients.
  - Symptoms in urolithiasis can result in premature labor and fetal loss.
  - Stones with obstruction may lead to urosepsis requiring appropriate treatment.
  - Calcium phosphate most common followed by calcium oxalate.

- **EPIDEMIOLOGY**
  - **Incidence**
    - Cystinuria in pregnant women occurs at a rate of 1/1,500 pregnant patients, a rate similar to that of nonpregnant females (0.03–0.5%).
    - Universal stones occur twice as often as kidney stones in pregnant patients.
    - Usually present in the 2nd or 3rd trimester.
    - Incidence—right vs. left side is similar.
    - Hispanics and whites more likely than blacks to develop stones during pregnancy.
    - Multiparous women are more commonly affected than are primiparous women.
  - **Prevalence**
    - N/A

- **RISK FACTORS**
  - **Dietary factors**
    - Relative immobility
    - Voluntary dietary modification (increased calcium)
  - **Genetics**
    - Increased stone formation is likely with a positive family history.
    - Factors related to stone formation tend to group in families.
    - Women with known cystinuria should obtain genetic counseling and management of the stone disease before becoming pregnant.

- **PATHOPHYSIOLOGY**
  - Several factors occur in pregnancy may enhance formation of stones:
    - Pregnancy-induced urinary tract
    - Hypercalcemia and hypercalciuria
    - Decreased renal perfusion
    - Physiologic hyperparathyroidism
    - Pregnancy-induced hypertension
      - Starts 6–20 wk, in 90% by 3rd trimester
    - Right side > left; may persist postdelivery
    - Infection
    - Associated higher incidence of maternal UTI (10–20%)
  - Stone passage can precipitate premature labor and/or interfere with normal labor.
  - Associated with higher incidence of maternal UTI (10–20%).
  - Store passage can precipitate premature labor and/or interfere with normal labor.

- **DIAGNOSTIC TESTS & INTERPRETATION**
  - **Lab**
    - **Urinalysis**
      - Hematuria/pyuria
    - **Serum collection**
      - UTIs are more common in pregnancy associated with stone disease (15–20%).
      - A UTI can induce premature labor.
    - **Serum creatinine**
      - May be lower if the increased GFR (25–50%) in pregnancy.
  - **Imaging**
    - **Renal ultrasound**
      - Standard initial imaging study in evaluation of pregnant patients (1).
      - Hydrocephalus
      - Renal stones/proximal ureteral stones
      - Dilation and decreased peristalsis allowed relative urinary stasis
      - Hydroureteronephrosis is the most significant renal anomaly reported on the fetus.
      - Resistive index (RI) > 0.70 in intrarenal arteries supportive of acute obstruction.
      - No radiation exposure to fetus.
  - **Transvaginal ultrasound**
    - Can demonstrate distal ureteral stones.
    - Can demonstrate pelvic jets, confirming urinary flow.
    - May be able to distinguish acute obstruction from the dilation of pregnancy.
    - Document the diameters of distal ureter.
    - Noncontrast helical CT
      - Although utilized increasingly in nonpregnant patients, delivers a relatively high radiation exposure.
      - Recent techniques have been decreased the radiation exposure.
    - **Other Imaging including standard excretory urogram and computed tomographic scan**
      - Abdominal radiographic and one excretory urogram has been widely used in pregnancy.
      - There has been no adverse effect of contrast material reported on the fetus.
      - **Radiation exposure is the major concern.**
        - Typical program gives 5–15 rads of exposure.
        - 5–15 rads to the maternal pelvis in the 1st trimester increases the risk of congenital anomalies by 1–3%.
        - As little as 0.4–1.0 rads of fetal exposure can increase the risk of childhood malignancy 2.4 times.
        - MRI urography
          - Effect on fetal development poorly defined.
          - May be able to distinguish acute obstruction from the dilation of pregnancy.
  - **Diagnostic Procedures/Surgery**
    - The presence of vesical calculus with obstruction is generally defined before interventional procedures.
    - Occasionally, the diagnosis is not certain and the presence of an obstructing calculus is defined only at the time of ureteroscopy.
Pathologic Findings

DIFFERENTIAL DIAGNOSIS
• Acute pyelonephritis
• Appendicitis
• Cholelithiasis
• Gastroenteritis
• Hypertension of pregnancy
• Neurologic/musculoskeletal pathology
• Obstetric pathology of pain
• Other intra-abdominal conditions
• Renal vein thrombosis

TREATMENT

GENERAL MEASURES
• Often misdiagnosed initially
• Appendicitis/diverticulitis/bacterial abruption
• Conservative measures are taken initially to manage pain and infection so that the stone may pass
• Hydration and analgesia, antianemics and antibiotics are used
• Approximately 60–80% of renal calculi pass spontaneously. Among pregnant patients with dilated ureter, the passage rate is not defined
• Urinary calculi associated with obstruction and upper tract infection demand immediate treatment with drainage and antibiotics

MEDICATION

First Line
• Narcotics including morphine, hydromorphone, butorphanol, meperidine, and acetaminophen can provide short-term pain relief without fetal harm
• Avoid codeine during pregnancy because of its association with fetal defects
• Nonsteroidal anti-inflammatory drugs are contraindicated because of the increased risk of miscarriage in the 1st trimester and other risks, including fetal renal anomalies, fetal pulmonary hypertension, and premature closure of the ductus arteriosus when used near term
• Medical management for the prevention of calcium stones should be delayed until after delivery

Second Line
• N/A

SURGERY/OTHER PROCEDURES
• Intervention may be required in 20–30% of cases (3)
• Drainage may be necessary
• Cystoscopy/stent placement can be done with or without ultrasound guidance (4)
• Stents must be changed every 6 to 8 wk because of rapid encrustation in the pregnant women’s urine
• Percutaneous nephrostomy placement can be done under ultrasound:
• To minimize radiation exposure
• The stone or obstruction can be addressed postpartum
• The tube should be changed every 6–8 wk
• Clearly tube drainage alone must consider the duration of pregnancy
• Ureteroscopy with laser lithotripsy or impact lithotripsy has been very successful in treating stones in the upper urinary tract in the pregnant patient
• Shock wave lithotripsy has generally not been employed because of concerns of safety and the readily available alternatives

ADDITIONAL TREATMENT

Radiation Therapy
• N/A

Additional Therapies
• N/A

Complementary & Alternative Therapies
• Dietary changes including:
  • Limiting high oxalate foods and purines
  • Increase in fluid intake
  • Limiting salt and sodium intake
  • May be best preserved until metabolic evaluation postpartum

ONGOING CARE

PROGNOSIS
• Pregnancy outcome is not appreciably worsened because of symptomatic urolithiasis with appropriate management (3)

COMPLICATIONS
• Premature labor, fetal loss
• Urosepsis, renal insufficiency

FOLLOW-UP

Patient Monitoring

• During gestation:
  • Conservative management with hydration
  • Indications for intervention:
    • Worsening renal function associated with persistent obstruction
    • Irretrievable pain
    • Obstruction of a solitary kidney
    • Persistent infection associated with an obstruction
    • Renal colic, precipitation premature labor that is refractory to treatment
• Preventive medications for stone disease have association with fetal defects
  • Penicillamine: Teratogenic in rats; fetal defects
  • Xanthine oxidase inhibitors: No adverse effects
  • Thiazides: Can cause fetal thrombocytopenia, hypoglycemia, and hyponatremia
  • Allopurinol: No adverse effects on fetal animals but effects on human fetus known
  • Propylene: Teratogenic in rats; fetal defects have been found in infants of mothers who took this during gestation

Postpartum:
• Metabolic screening should be undertaken postpartum and should be delayed until completion of lactation period

Patient Resources
• N/A

CODES

ICD9
• 596.1 Calculus of ureter
• 596.9 Urinary calculus, unspecified
• 646.80 Other specified complications of pregnancy, unspecified as to episode of care or not applicable

ICD10
• N91.1 Calculus of ureter
• N92.9 Urinary calculus, unspecified
• O98.9/O98.0 Other specified diseases and conditions comp pregnancy

CLINICAL/SURGICAL PEARLS
• Most urinary stone pain
• Intactable pain or infection with obstruction may necessitate drainage
• Catheter, ureteral stent, or percutaneous nephrostomy (must be changed frequently at 4 to 6 wk because of the risks of encrustation)
• Ureteroscopic treatment with endoscopic lithotripsy appears to be the most efficacious and possibly safest treatment.
PRIAPISM
Hunter Wessells, MD, FACS
Brad Figler, MD

DESCRIPTION
- Prolonged, usually painful erection, occurring in the absence of sexual stimulation
- Named for Priapus, the Greek god of fertility who had an oversized, eternally erect penis
- Ischemic priapism (low-flow, veno-occlusive) is most common: Compartment syndrome of the erectile bodies causing ischemia, and ultimate necrosis of the cavernosal smooth muscle
- Nonischemic priapism (high-flow, arterial) is less common: Uncontrolled arterial inflow into the cavernosal sinusoids without ischemia or necrosis of cavernosal smooth muscle

Incidence
- FDA data (2007): 93 cases due to PDE5 inhibitors

PATHOPHYSIOLOGY
- Ischemic priapism comprises the great majority of cases of prolonged erection
  - Ischemic priapism is caused by a veno-occlusive phenomenon in which a variety of environmental factors lead to hypoxia, acidosis, and downregulation of cavernosal smooth muscle relaxation leading to persistent veno-occlusion, a compartment syndrome, with absent further arterial inflow
  - A feature of ischemic priapism is the ischemia reperfusion injury and oxidative stress that occurs after release of the ischemic insult
  - Hematologic abnormalities generally cause a low-flow state with little arterial ulceration and veno-occlusion (sickle cell disease, thrombophilia, leukemic infiltration, sepsis, encephalitis, hemorrhage with heparin, total parenteral nutrition)

Diagnosis
- Color Doppler US imaging of the cavernous arteries
- Hemoglobin electrophoresis
- Urethral catheterization

ASSOCIATED CONDITIONS
- Alcohol abuse, psychiatric disorders
- Attention deficit hyperactivity disorder (ADHD): Methylphenidate use
- Blood dyscrasias
  - Cocaine abuse
  - Epidural anesthesia and analgesia
- Hemoglobinopathies
- Hypercoagulable states
- Intracavernous or intravaginal ED therapy
- Oral PDE5 inhibitors ( sildenafil, etc.)

DIAGNOSTIC TESTS & INTERPRETATION
- CBC with differential and platelet count
- Retinoblastoma (may be increased in sickle cell disease)
- Sickle cell prep for “S” hemoglobin
- Hemoglobin electrophoresis
- Urine toxicology for prohibited drugs

DIAGNOSTIC PROCEDURES/SURGERY
- Administration of cavernosal blood with a “coralike needle” and blood gas sampling for “penile blood gas” allows differentiation between ischemic priapism (low pH, low PO2, high PCO2, blood is very dark) vs. nonischemic priapism (normal penile blood gases, blood is bright red). Typical values:
  - Ischemic priapism (pH < 7.1, PO2 < 40 mm Hg, PCO2 > 60 mm Hg, pH < 7.15)
  - Nonischemic priapism (pH > 7.4, PO2 > 60 mm Hg, PCO2 < 40 mm Hg, pH > 7.4)

Pathologic Findings
- Initially liquefactive necrosis of the corporal tissue; later corporal smooth muscle fibrosis

DIFFERENTIAL DIAGNOSIS
- Ischemic vs. nonischemic priapism
- “Pseudo-priapism” in men with pelvic prosthetics, vacuum constriction device with band, intravaginal foreign body causing penile rigidity
TREATMENT

GENERAL MEASURES
- Appropriate differentiation between ischemic and nonischemic priapism is critical (1).
- Ischemic priapism of longer than 4 hr duration is a urologic emergency that requires prompt penile decompression. This is usually a bedside corporal aspiration with or without irrigation.
- Appropriate candidate for “penile blood gas” - Duplex color ultrasound has been suggested in lieu of penile blood gas to differentiate ischemic and nonischemic priapism.
- All patients should undergo monitoring of blood pressure and pulse, peripheral IV placement, appropriate use of pain medication and sedation.

MEDICATION
First Line (1)
- **Ichoric priapism**
  - Use local anesthesic (lidocaine without epinephrine) and choose technique (local injection site, dorsal nerve block, etc.).
  - Corporal body aspiration – irrigation with dilute adrenergic agent
  - Phenylephrine (10-50 mg/ml) 1-4 ml directly into the corpora every 3-5 min until a response. Can be repeated to a max of 1.5 mg phenylephrine has been administered or a total of 1 hr (if no response after 1 hr should be considered initial treatment failure)
  - Use lower volumes in children or with significant cardiovascular disease
  - Corporal compression helps facilitate the process
  - This technique has best results for priapism <24 hr in duration.
  - Aspirate with a large needle (16-18G) connected to a 90-ml syringe and a 3-way stopcock. Insert the needle perpendicular into the skin into the lateral aspect of the corpora and aspirate 20-30 ml at a time (the glans is a less desirable site). Continue until the dark ischemic blood turns bright red.
  - If not successful, aspirate and irrigate the corpora with dilute solution of phenylephrine (10 mg in 500 ml saline) using 10-20 ml each time. When aspirations and irrigations are completed, apply pressure for 5-10 min to limit hematoma and swelling of corpora.
- Ischemic priapism is sickle cell disease:
  - Opioid, analgesic, aggressive hydration, and supplemental oxygen - 4-4 hr treatment
  - Standard treatment if > 4 hr, as for ischemic priapism above
  - Terbutaline or other oral agents not recommended per AUA guidelines.
- Nonischemic priapism
  - No role for pharmacologic therapy
  - Stuttering priapism
  - Treat as for ischemic priapism
  - Urinary antispasmodics may be considered (but not for children/adolescents)
  - Intracavernous self-injection who fail or reject systemic treatment

Second Line
- Injection of isosorbine (1 mg in 1,000 ml saline) has been used in place of phenylephrine; however, phenylephrine is more of a pure α-agonist with a lower systemic side effect profile

SURGERY/OTHER PROCEDURES
- Surgical intervention is considered 2nd line after corporal aspiration and attempts fail
- **Ichoric priapism**
  - If aspiration/irrigation fails, cavernosal glanular shunting is recommended; creating a fistula between the corpora cavernosa and the glans. Unilateral usually sufficient; if not successful perform bilateral procedure
  - Distal cavernosal glanular shunt is 1st line
  - Winter shunt: 16G core biopsy needle passed through the glans and tunica to the meatus on both sides, and rotated (blade-edge 90 degrees laterally). Consider proximal shunting if distal shunting fails
  - Cavernosal–spongiosal shunt

- **Nonischemic priapism**
  - No role for shunting in nonischemic priapism
  - Conservative measures are appropriate in the short term as nonischemic cases of priapism do not lead to underlying cavernosal tissue damage
  - Duplex Doppler ultrasonography with color flow to localize potential abnormal vascular accumulation (arteriovenous fistula, see image)
  - Internal pudendal arteriography with selective embolization (cath or gel foam)
  - Surgical exploration of the cavernosal body and ligating in cases refractory to embolization

ADDITIONAL TREATMENT
- **Radiation Therapy**
  - Immediate placement of penile prosthesis if priapism is of significantly prolonged duration and ED is highly unlikely is advocated by some
- Complementary & Alternative Therapies

ON GOING CARE
- **PROGNOSIS**
  - Based on duration/ severity of ischemia. Priapism associated with sickle cell disease may resolve in 35% of patients treated systemically.
  - Risk of permanent erectile dysfunction increases substantially after 24 hr of ischemic priapism (92% potency preserved with < 1 day of priapism vs. 69% or less if more prolonged) (2).
  - Monitoring of ischemic priapism may be clinical (complete flaccidity of the penis) or radiologic (color duplex Doppler ultrasonography showing persistent flow in cavernosal artery)

COMPLICATIONS
- Erectile dysfunction, particularly with cases of prolonged ischemic priapism
- Cavernosal urethral fistula (after cavernosal spongiosal shunt)
- Cavernositis and corporal fibrosis
- Penile deformity

FOLLOW-UP
- **Patient Monitoring**
  - Cavernosal Priapism should be monitored for development of erectile dysfunction
  - Patient should undergo appropriate testing to complete workup for any hematologic abnormalities or other potential underlying causes

Patient Resources
- AUA Foundation. www.auanet.org/education/guidelines/priapism

REFERENCES

ADDITIONAL READING
- N/A
- See Also (Topic, Algorithm, Media)
- Priapism Algorithm
- Sickle Cell Disease, Ediologic Considerations

CODES
- ICD10: N48.33 Priapism
- ICD9: N/A

CLINICAL/SURGICAL PEARLS

- The hallmark of a priapism: Corpora are involved but the glans is flaccid and soft.
- Penile blood gas allows appropriate diagnosis.
- Ischemic priapism is an emergency and intervention should start within 4-6 hr, including decompression of the corpora cavernosa by aspiration and intra cavernous injection of sympathomimetic drugs (eg, phenylephrine).
- Nonischemic priapism can be managed in a semielective manner once diagnosis confirmed.
RISK FACTORS

- For the diagnosis of prostate cancer:
  - Older age
  - Family history of prostate cancer

- For infectious complications the following have been suggested as risk factors:
  - Number of previous prostate biopsies was suggested as risk factors:
  - Family history of breast cancer
  - African American race
  - Older age
  - 1st-degree relatives with prostate cancer

ASSOCIATED CONDITIONS

Benign prostate hyperplasia

GENERAL PREVENTION

Consult urine culture before prostate biopsy if there is any concern over subclinical UTI

PROCEDURE ENEMA does not appear to have any impact on complication rates

Continuing or resuming of antibiotics or anti-inflammatory medications prior to biopsy is based upon risk/benefit for each patient. Consider discussion with the patient’s cardiologist or primary care physician as needed

DIAGNOSIS

PHYSICAL EXAM

Digital rectal exam may reveal nodularity, induration, or an asymmetry (gland)

Additional biopsy of palpable nodule or hypoechoic areas may be performed at the discretion of provider

DIFFERENTIAL DIAGNOSIS

- ASCAP
- Benign prostatic hyperplasia
- No evidence of malignancy

TREATMENT

GENERAL MEASURES

Although many clinicians have patients perform a self-administered enema, this is not needed. There is little evidence to support their use.

MEDICATION

First Line

- For our institution (Cleveland Clinic), patients receive an oral single dose of fluoroquinolone as well as a single-dose of intramuscular antistaphylococcal beta-lactam (80 mg gentamicin)
- AKI guidelines (see “Complications” below)

Second Line

None

SURGERY/OTHER PROCEDURES

- For patients with anterior rectal maneuvers or previous colorectal operations preventing TRUS, a transperineal biopsy can be performed.
- The increasing incidence of antibiotic resistance with increasing concerns of the risk of sepsis is favoring renewed interest in transperineal biopsy as a relatively sterile alternative to standard TRUS-guided biopsy.

PATHOPHYSIOLOGY

- Normal adult prostate is approximately 10 g
- The majority of prostate cancer is adenocarcinoma and located in the peripheral zone of the prostate
- In the absence of antibiotic prophylaxis, bacteremia and bacteriuria occur in 16% and 44% respectively of transrectal ultrasound-guided prostate biopsy

ASSOCIATED CONDITIONS

Benign prostate hyperplasia

GENERAL PREVENTION

- Consult urine culture before prostate biopsy if there is any concern over subclinical UTI
- Procedure enema does not appear to have any impact on complication rates
- Rectal swab with culture and sensitivity has been suggested as a method to identify potentially resistant pathogens and is not considered standard of care
- Transperineal biopsy may have a lower rate of infection than the transrectal approach
- Transperineal biopsy strategy using local anesthesia may result in a potential for decreased discomfort and pain
- Additional biopsy of palpable nodule or hypoechoic areas may be performed at the discretion of provider

Pathologic Findings

- Prostate adenocarcinoma
- Prostatic intraepithelial neoplasia (PIN)
- Atypical small acinar proliferation (ASAP)
- Benign prostate tissue

DIFFERENTIAL DIAGNOSIS

- ASCAP
- Benign prostatic hyperplasia
- No evidence of malignancy

TREATMENT

GENERAL MEASURES

Although many clinicians have patients perform a self-administered enema, this is not needed. There is little evidence to support their use.

MEDICATION

First Line

- For our institution (Cleveland Clinic), patients receive an oral single dose of fluoroquinolone as well as a single-dose of intramuscular antistaphylococcal beta-lactam (80 mg gentamicin)
- AKI guidelines (see “Complications” below)

Second Line

None

SURGERY/OTHER PROCEDURES

- For patients with anterior rectal maneuvers or previous colorectal operations preventing TRUS, a transperineal biopsy can be performed.
- The increasing incidence of antibiotic resistance with increasing concerns of the risk of sepsis is favoring renewed interest in transperineal biopsy as a relatively sterile alternative to standard TRUS-guided biopsy.
PROSTATE BIOPSY, INFECTIONS AND COMPLICATIONS

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- A retrospective analysis from Israel suggests that a single injection of 240 mg gentamicin along with a quinolone for 3 days significantly reduces infectious complications.
- Another case series demonstrated that 500 mg intravenous amikacin 30 min before the biopsy along with several days of ciprofloxacin reduced the incidence of urosepsis/septicemia following prostate biopsy.

Complementary & Alternative Therapies

Topical lidocaine with povidone-iodine reduced in a 62% reduction in infectious complications in a prospective clinical trial but was not statistically significant.

ONGOING CARE

PROGNOSIS

Although prostate biopsy is usually generally safe and well tolerated, it is an invasive procedure that is not without risk and required a clear understanding through informed consent of the patient.

COMPLICATIONS

- Bleeding is the most common complication and includes hematuria, hematospermia, and rectal bleeding.
- Bleeding is usually self-limiting, and resolves with conservative measures. More significant bleeding has been reported and may require transfusion or colostomy intervention.
- The 2nd most common complication is infection.
  - The incidence of infectious complications, including sepsis, is increasing.
  - Compared to controls, men undergoing biopsy have a significant risk for serious infection requiring hospitalization (approximately 2.2% risk increase and 2.5% risk increase, respectively).
  - Updated AUA Best Practice Policy Panel (BPP) 4.

Antibiotic prophylaxis should be given for all prostate biopsy procedures. Duration of therapy is 24 h. Recommended 1st/2nd/3rd generation cephalosporin.

- Fluoroquinolones or
- Trimethoprim-
- Sulphamethaxazole (TMP-SMX) or

- Aminoglycosides (Aztreonam can be substituted for aminoglycosides in patients with renal insufficiency).
- Familiarity with local resistance patterns including fluoroquinolone-resistant bacteria is important.

FOLLOW-UP

Patient Monitoring

- Prompt medical evaluation for patient with signs and symptoms of infection or significant bleeding.
- Counseling regarding transient hematuria and the potential for hematospermia that may last for several weeks.
- Follow-up of prostate biopsy results

Patient Resources

ADDITIONAL READING

See Also (Topic, Algorithm, Media)

- Prostate Cancer, General
- PSA Elevation
- Urgency

CODES

ICD9

- B52.9 Unspecified disorder of prostate
- 998.19 Other postoperative infection
- 998.9 (unspecified complication of procedure, not elsewhere classified)

ICD10

- N42.9 Disorder of prostate, unspecified
- I91.400A Infection following a procedure, initial encounter
- T81.9XXA Unspecified complication of procedure, not elsewhere classified

CLINICAL/SURGICAL PEARLS

- A minimum of 12 cores is considered standard of care in the United States.
- Additional biopsy of nodules and hypoechoic areas may be needed.
- Be familiar with local resistance patterns when selecting antibiotic prophylaxis.
- In men with prostate cancer on active surveillance the number of previous prostate biopsies may be associated with a significant risk of infectious complications and every previous biopsy increases the risk of infectious complication.
PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING CRYOTHERAPY

Michael C. Large, MD

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- PSA spikes initially from necrosis of the prostate tissue
- Following cryotherapy PSA rechecked every 3 mo × 1 yr, then every 6 mo thereafter
- PSA may not decrease to undetectable
- PSA-based definition for biochemical recurrence is not standardized. Various parameters used:
  - PSA > 0.4 ng/mL, > 0.5 ng/mL, > 1.0 ng/mL
  - 3 consecutive increases (“ASTRO” definition)
  - Nadir + 2 ng/mL (“Phoenix” definition)

Imaging
- Complete metastatic workup may include:
  - CT
  - MRI of bones

Diagnostic Procedures/Surgery
- Transrectal biopsy
  - Commonly performed post-cryotherapy
  - Recommend waiting 6 mo for inflammation to resolve
- Negative biopsy reported in 75–95% (1B), (2C)

DIFFERENTIAL DIAGNOSIS
- Necrosis, especially if within 3 mo of procedure
- Treatment failure
- Recurrent disease (local or metastatic)

TREATMENT

GENERAL MEASURES
- Confirmation of recurrence via transrectal biopsy

MEDICATION

First Line
- No first-line medication therapy
  - Consider androgen-deprivation therapy or clinical trial if metastatic disease
  - No significant data on the use of androgen-deprivation after local cryotherapy failure

Second Line
- PSA

SURGERY/OTHER PROCEDURES
- Salvage prostatectomy feasible but large series are lacking
  - Reported techniques include:
    - Open retropubic or perineal
    - Laparoscopic or robotically assisted
  - Salvage cystoprostatectomy with urinary diversion
  - Option for extensive local recurrence with severe, treatment-refractory lower urinary tract symptoms

ADDITIONAL TREATMENT

Radiation Therapy
- Conformal or intensity-modulated radiotherapy
  - Largest series 49 patients, received conformal RT
  - Mean preadmission PSA 2.4 ng/mL
  - Mean RT dose 62.9 Gy
  - At median follow-up 32 mo, biochemical-free survival rate 61%

Additional Therapies
- Repeat cryotherapy
  - Largest series 32 patients (4C)
  - Median follow-up 63 mo
- 22, 23, and 29 were biochemical disease free by definitions of 0.5 ng/mL, 1.0 ng/mL, and ASTRO definition

Complementary & Alternative Therapies
- None widely studied
PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING CRYOTHERAPY

ONGOING CARE

PROGNOSIS
- Biochemical recurrence-free survival after primary cryotherapy (Phoenix definition)
  - 5-yr estimates based on D’Amico risk category:
    - Low risk: 85–90%
    - Intermediate risk: 80%
    - High risk: 60–70%
  - 10-yr estimates based on D’Amico risk category:
    - Low risk: 80%
    - Intermediate risk: 75%
    - High risk: 45%

COMPICATIONS
- No large series following postcryotherapy salvage treatment
- Surgery:
  - Intraoperative rectal injury
    - Small injury: 2-layer primary repair and omental interposition
    - Large injury, gross spillage, poor tissue viability:
      - Primary repair and diverting colostomy
  - Urinary incontinence, impotency
- Radiation
  - Rectourethral fistula, urethral stricture, urinary incontinence, impotency, and bladder and rectal toxicities
- Repeat cryotherapy
  - Rectourethral fistula, urethrocutaneous fistula, urethral stricture, urinary incontinence, impotency, and bladder and rectal toxicities

FOLLOW-UP

Patient Monitoring
- No standards exist for postcryotherapy recurrence follow-up
- If biochemical disease untreated, may treat patient according to algorithms for (1) localized or (2) advanced prostate cancer outlined in prior chapters
- If patient has undergone salvage treatment after cryotherapy, no standards exist
  - PSA often performed every 3 mo after salvage therapy
  - Re-biopsy may be offered 6 mo after treatment, or if clinically indicated

Patient Resources

- Prostate Cancer, Biochemical Recurrence (Elevated PSA) Following Radiation Therapy
- Prostate Cancer, Biochemical Recurrence (Elevated PSA) Following Radical Prostatectomy
- Prostate Cancer, General
- PSA Elevation, General Considerations
- Reference Tables: TNM: Prostate Cancer

CODES
ICD9
- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen (PSA)

ICD10
- C61 Malignant neoplasm of prostate
- R97.2 Elevated prostate specific antigen (PSA)
- Z85.46 Personal history of malignant neoplasm of prostate

CLINICAL/SURGICAL PEARLS
- An early rise in PSA after cryotherapy is normal, and further testing should be deferred until at least 3 mo following treatment
- Various definitions of PSA failure after cryotherapy exist: >0.4 ng/mL, >0.5 ng/mL, >1.0 ng/mL, 3 consecutive rises, and nadir + 2 ng/mL
- Prostate biopsy is useful in the workup of postcryotherapy biochemical recurrence
- Postcryotherapy treatment of recurrent disease should be reserved for highly experienced surgeons and radiation oncologists
PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADIATION THERAPY

Robert B. Den, MD
Mark Hurwitz, MD

ASSOCIATED CONDITIONS
Symptoms of urinary outlet obstruction can occur but are uncommon during the initial period of biochemical recurrence.

GENERAL PREVENTION
- Optimized radiation therapy including dose escalation with daily image guidance to ensure proper targeting with external beam irradiation and use of proper brachytherapy techniques
- Use of androgen deprivation in combination with radiation for high risk and selected intermediate risk patients

DIAGNOSIS

HISTORY
- Prior radiation treatment information should be obtained including type of radiation, technique, and dose prescribed. For prostate brachytherapy postimplant dosimetry analysis should be reviewed to determine if there were underdosed regions.
- Thorough assessment of general health with emphasis on urinary and bowel function is important in guiding the advisability of potential salvage therapies.

PHYSICAL EXAM
General physical exam including rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- PSA. – In addition to total PSA, PSA kinetics may be helpful in identifying patients at greater risk of development of distant vs. local recurrence.
- Patients with short time to PSA nadir after treatment and short doubling times (PSADT) are at greater risk of subsequent diagnosis of metastatic disease (PSADT < 3–6 mo).
- Testosterone establishes baseline for future hormonal intervention
  - Basic metabolic panel
  - CBC

Imaging
- Bone scan
- CT of abdomen and pelvis
- Pelvic/rectal MR. Magnetic resonance spectroscopic imaging may improve results over MR alone.
- New techniques for PET/CT including use of [18F]Fluorodeoxyglucose may be useful in select cases
- Other imaging as clinically indicated

Diagnostic Procedures/Surgery
- Prostate biopsy should be considered if more than 2 yr have elapsed since completion of radiation therapy and additional local therapy is being contemplated.
  - As the full effects of radiation are not manifested for 24–30 mo, biopsy before this time is not indicated.
  - Approximately 20% of patients who have prostate irradiation biopsies will have no clinical evidence of disease with additional long-term follow-up.
  - Conversely, given the limitations of sampling, local recurrence may be present despite negative biopsy.
  - Biopsy to assess findings concerning for distant metastases as clinically indicated.

Pathologic Findings
- Occurrence of prostate cancer in ipsilateral nodal metastases as clinically indicated.

DIFFERENTIAL DIAGNOSIS
- PSA bounce phenomenon
  - 35% incidence after brachytherapy
  - Less common with external beam radiation
  - Testosterone rebound after completion of androgen deprivation with associated rise in PSA

TREATMENT

GENERAL MEASURES
- Efforts should be made to discern if biochemical recurrence is due to presence of local vs. distant disease or a combination of both.
- In the presence of metastatic disease androgen ablation is the standard choice.
- In cases of only localized disease there are many more options including observation, androgen ablation or salvage therapies including radical prostatectomy or cryotherapy.
  - In general candidates for local salvage therapy should have original clinical stage tumor T1, T2 N0M0, life expectancy of ≥ 10 yr, and a PSA < 10 ng/mL (1)
  - Patient who are not ideal candidates for salvage therapy should be treated by androgen deprivation or observation
MEDICATION

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies

- Thermal ablative therapies including cryosurgical and high-intensity focused ultrasound remain investigational.
- Cryotherapy in particular has shown promise in selected series.
- 5–10 yr freedom from biochemical recurrence with cryotherapy ranges between 34–59%.
- Rates of ≥3 GU and GI complications average approximately 10% and 3% across reported series.
- Focal ablative therapies that attempt to identify the site of recurrence and ablate the site are investigational (5).

Complementary & Alternative Therapies

Low-fat diets and diets high in polyphenols as found in broccoli, turmeric, pomegranate, and green tea may be beneficial.

PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADIATION THERAPY

PEARLS

ON GOING CARE

Ongoing Care

- Participation in clinical trials should be encouraged in areas such as this where no consensus exists.

ADDITIONAL READING

- PSA, General Considerations
- Reference Tables: TNM: Prostate Cancer
PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADICAL PROSTATECTOMY
Gurdarshan S. Sandhu, MD
Gerald L. Andriole, MD, FACS

ASSOCIATED CONDITIONS
- Biochemical recurrence of PSA after surgery when the PSA after surgery was initially undetectable
- Generally predicts metastatic progression and prostate cancer specific mortality by a median of 8 and 13 yr, respectively (4)
- Importantly, not all men with biochemical recurrence will develop metastases or die of prostate cancer (1)
- PSA doubling rate after recurrence is an important factor in assessing the risk of subsequent metastases and prostate cancer mortality

GENERAL PREVENTION
- Although proper surgical technique can limit the risk of PSA recurrence it cannot be guaranteed to do so due to varying tumor biology

DIAGNOSIS

HISTORY
- Preoperative PSA
- Time since surgery
- Pathologic information from the radical prostatectomy
- Postoperative continence and erectile function

PHYSICAL EXAM
- Digital rectal exam to palpate for local recurrence in the prostate bed

DIAGNOSTIC TESTS & INTERPRETATION
- PSA level can vary depending on the lab assay
- PSADT assessment (can be calculated using widely available online calculators)
- Imaging evaluation is necessary to determine if distant metastases are present under some circumstances (eg, short PSA doubling time (PSADT) after recurrence

TREATMENT

GENERAL MEASURES
- Close monitoring of the serum PSA postoperatively
- NCCN Guidelines recommend PSA every 3 mo. A high risk or 6–12 yr up to 5 yr, then annually thereafter, annual DRE
- Follow up treatment decision primarily based on pathology, imaging, and PSA dynamics
- Can include observation, androgen ablation, or pelvic radiation
- Can continue to be considered with slow PSADT, in older patients with other comorbidities

MEDICATION

First Line
- Androgen-deprivation therapy (ADT)

ADT drug classes include Gonadotropin-Releasing Hormone (GnRH) agonists (eg, goserelin, leuprolide, and testosterone (DepoTesta)
- Depot injections of the GnRH agonists allow dosing to extend from 28 days to 1 yr
- GnRH antagonist dosing is every 28 days
- Use “Prostate Cancer metastatic” for more information on drug classes
Therapies

Clinical trials should be available and offered.

ADDITIONAL TREATMENT

SURGERY/OTHER PROCEDURES

- Scrotal orchietomy
  - Can be used instead of ADT
  - Is more cost effective than ADT
  - Does not allow for intermittent androgen deprivation
- Subcapsular scrotal orchietomy can also be offered in lieu of ADT
  - Does not allow for intermittent androgen suppression, the role of ADT as monotherapy may be somewhat limited

Second Line

See “Prostate Cancer, metastatic” and “Prostate Cancer, rising PSA following androgen ablation” for more information on additional drug classes.

PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADICAL PROSTATECTOMY

ONGOING CARE

PROGNOSIS

- Prognosis is dictated by several variables including:
  - Preoperative PSA
  - Pathologic Gleason score
  - Pathologic tumor stage
  - Time to biochemical recurrence
  - PSA=0.3–6 ng/mL associated with the development of metastatic disease
  - For those patients that progress after biochemical recurrence, in general, metastatic progression and prostate cancer specific mortality occur at a median of 8 and 13 yr after biochemical recurrence

COMPLICATIONS

- Patient anxiety
- Complications are dictated by adjuvant and salvage therapy offered
  - Either radiation or ADT

FOLLOW-UP

Patient Monitoring

- Monitoring of serum PSA is necessary to diagnose biochemical recurrence and the response to treatment when/if it is offered
- For patients on ADT, baseline and periodic assessment of bone density is recommended
- If PSA begins to rise on ADT, serum testosterone should be assessed to ensure a castrate level

Patient Resources

- NCCN. http://www.nccn.org/patients/patient_gUidelines/prostatecancer/index.html

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)

- Prostate Cancer, General
- Prostate Cancer, Locally Advanced (Pathologic T3, T4)
- Prostate Cancer, Metastatic (Clinical and Pathologic N+, M+)
- PSA evaluation, General Considerations
- PSA, General Considerations
- Reference Tables: TMM: Prostate Cancer

CODES

ICD9

- 181 Maligant neoplasm of prostate
- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen (PSA)

ICD10

- C61 Malignant neoplasm of prostate
- D94.77 Acquired absence of organ, genital organs

CRITICAL/SURGICAL PEARLS

- Distinguishing local from systemic disease recurrence dictates adjuvant/salvage therapy options.
- Adjuvant/salvage surgery is supported by randomized trials for patients with adverse pathology at the time of prostatectomy and is endorsed by AUA/ASTRO Guidelines.

Additional Therapies

Clinical trials should be available and offered.

Complementary & Alternative Therapies

No data are available on the optimal PSA value at which to initiate treatment.

- ADT is potentially detrimental to cognitive function, quality of life, sexual health, cardiovascular risk, and bone integrity
- Timing of initiation of ADT should be based on a patient’s risk of metastatic progression and risk of death from disease as opposed to absolute PSA levels
- When ADT is initiated, in the absence of metastases, intermittent ADT is preferred to continuous ADT given the side effects of this treatment and the non inferior overall survival of intermittent ADT (3)
- With the benefits that have been observed with adjuvant/salvage radiation, the role of ADT as monotherapy may be somewhat limited
**DESCRIPTION**
Prostate cancer (CaP) usually refers to adenocarcinoma in other types are rare.

**EPIDEMIOLOGY**
Incidence/Prevalence
- Most common solid tumor in US males.
- 2014: 233,000 new cases; 29,480 deaths.
- Advent of PSA blood test led to a sharp increase of CaP incidence from 1989 to 1993.
- Highest worldwide incidence is in African Americans, with a relative incidence of ~2 compared to US whites.
- Lowest worldwide incidence is in Asian men (1.9/100,000 yr in China), however, Asians who immigrate to US increase risk to that of US men.
- Mortality rate decreased sharply since 1991, now lower than before PSA era.
- 5-yr relative survival rates ~100%.
- Lifetime CaP risk is 16-15%.

**RISK FACTORS**
- Genetic and environmental factors are important in CaP development.
- Family history. Risk is increased by number of affected family members, degree of relation, and age at diagnosis.
- Infection/Inflammation: Prostatitis and STDs.
- Diet: Several genetic determinants of CaP code for proteins that repair oxidant stress.
- Western diet (high levels of meat, dairy, and saturated fat); folate supplements.
- Antidepressants: Essential for development and maturation of prostate gland.
- Lack of androgen associated with decreased risk of CaP. Although this down-stream relationship has been established.
- Shrinked CAG repeat length in the AR gene associated with increased risk.
- Exogenous: Metabolic effects on CaP.
- IGF-1.
- Vitamin D may protect against CaP.

**PATHOPHYSIOLOGY**
- Normal adult prostate 20-25 g; secretes fluid comprising about 30% of ejaculate.
- Most CaP arise in peripheral zone of gland.
- High-grade prostatic intraepithelial neoplasia (HGPIN) may be a premalignant lesion.
- Risk of CaP on subsequent biopsy 16-44%, repeat biopsy within a year not necessary unless other signs of cancer.
- Atypical small acinar proliferation (ASAP) considered premalignant; 43-49% risk of cancer, biopsy should be repeated.

**ASSOCIATED CONDITIONS**
- EOD and urinary incontinence are associated with all local CaP therapies.

**GENERAL PREVENTION**
- Randomized trials have been conducted.
- Prostate Cancer Prevention Trial (PCPT) (finasteride vs. placebo) while there was 23-25% reduction in CaP risk, concern over slight increase in diagnosis of high-grade cancer prevented those from being FDA-approved agents.
- SELECT: Examined antioxidant Vit E and selenium terminated in 2008 due to lack of benefit.
- Increased risk of CaP and diabetes.

**DIAGNOSIS**
- History: Rarely presents with symptoms; most cases are detected by PSA screening and/or DRE.
- Physical exam: Induration, nodularity, or asymmetry in the gland (uncommon in most men).
- Staging:
  - Intermediate: T2b–T2c/Gleason 7/PSA <10 ng/mL.
  - High: T3a or greater or Gleason score 8–10 or PSA >10 ng/mL.

**DIAGNOSTIC TESTS & INTERPRETATION**
- PSA is typically elevated in serum of patients with CaP (See Section I: PSA Elevation, General).
- Pulsed wave Doppler ultrasound and color Doppler imaging of the prostate.
- TRUS-guided needle biopsy extended template now standard (10–12 cores).
- Bone scan: Usually ordered in intermediate- and high-risk patients, blastic bone lesions w/mets.
- CT abdomen/pelvis: Used to assess for visceral or lymph node metastases, indicated for intermediate- and high-risk.
- Prostate-specific antigen assay (PSMA) monoclonal antibody, FDA-approved post-prostatectomy, limited use.

**TREATMENT**
- Localized disease, best treatment controversal and must be individualized; includes active surveillance, radical prostatectomy, radiation therapy, cryosurgery.
- Consider age, overall health, life expectancy, patient and physician preferences.
- Metastatic CaP: Long-term, hormone therapy, chemotherapy.

**DIFFERENTIAL DIAGNOSIS**
- Localized: BPH, prostatitis (granulomatous, acute, chronic), recent instrumentation, nonadenocarcinoma prostate malignancy (cancer, uterine carcinoma).
- Metastatic: Papillary disease, other causes of bladder or prostatic lymphomatoid hyperplasia (lymphoma, TB, etc.).
**Radiation Therapy**

**ADDITIONAL TREATMENT**

**Second Line**

**First Line**

**MEDICATION**

**External beam RT:**
- Cryotherapy uses multiple probes to ablate prostate
- Bilateral orchiectomy provides permanent androgen deprivation

**Radical prostatectomy:**
- For low-risk (T1 and T2a) cancer, 5-yr biochemical disease-free rate is >90%

**Hypofractionation approaches in clinical trials**

**Active surveillance:**
- Selection of patients with low-risk disease
- Initial PSA ≤10 ng/mL; biopsy negative

**Additional Therapies**

**PROSTATE CANCER, GENERAL**

**Gleason score (≥7), high PSA (≥10 ng/mL), and ≥12 biopsies positive (≥50% cancer in any site)**

**Radical prostatectomy:**
- Resection of prostate and seminal vesicles and hypogastric nerves of bladder to urethra

**Neoadjuvant or concurrent androgen deprivation for 6 mo–1 yr with XRT increases survival vs. XRT alone or hormonal therapy alone (select intermediate and high-risk patients)**

**For nodal metastases**
- Androgen deprivation may be considered in men at high risk

**SURGERY/OTHER PROCEDURES**

**Prostatectomy:**
- Open (retropubic, perineal), laparoscopic, or robot-assisted laparoscopic
- Nerve-sparing technique if possible

**PSA every 6–12 mo after radiation for 5 yr; yearly after:**
- 5 yr; yearly after:
- 5 yr
- Bladder outlet obstruction, bone pain, pathologic fracture, seminal vesicle invasion, capsular penetration, lymph node involvement
- New genomic markers available for prognosis (See Section III: “Prostate Cancer, Genomic markers.”)

**Therapy related:**
- Local therapy (surgery, radiation): impotence, incontinence, rectal injury
- Androgen deprivation: hot flashes, loss of libido, impotence, fatigue, osteoporosis

**Follow-up Patient Monitoring:**
- PSA every 6–12 mo; if ≥5 ng/mL, yearly after prostatectomy
- Should drop to <0.5 ng/mL after radiation for best prognosis
- BMI every other year
- CT of abdomen/pelvis and/or bone scan if patient has new bone pain, rapid PSA rise, short doubling time

**REFERENCE**

**ADDITIONAL READING**

**Patient Resources**

**ICD9**

- 61.9 Malignant neoplasm of prostate
- 61.9 Inflammatory disease of prostate, unspecified
- 280.42 Family history of malignant neoplasm of prostate

**ICD10**

- C61 Malignant neoplasm of prostate
- N41.9 Inflammatory disease of prostate, unspecified
- Z08.42 Family history of malignant neoplasm of prostate

**Prostate cancer requires informed decision making and a risk-based approach; consider surveillance if low risk and <10 yr life expectancy.**
PROSTATE CANCER, LOCALIZED (T1, T2)
Nicholas J. Kuntz, MD
Judd W. Moul, MD, FACS

DIAGNOSIS

HISTORY
- LCP is rarely symptomatic
- Unintentional weight loss or new onset skeletal pain suggests nonlocalization disease
- LUTS
  - More commonly attributed to BPH

PHYSICAL EXAM
- Digital rectal exam (DRE)
  - No palpable nodule (cT1)
    - Radiodense confined to prostate gland (T2)
  - Abnormal texture or palpable seminal vesicles suggests more advanced disease than T2

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Prostate specific antigen (PSA)
  - Produced by prostatic epithelium
  - Half-life of 2–3 days; Not specific to CaP
  - A continuous parameter
  - The higher the value, the more likely the existence of CaP (1][A]
- Routine PSA screening is controversial
  - 2013 AUA Guidelines (2):
    - Under age 40 y: Do not screen (C)
    - 40–54 y: average risk: Do not screen (C)
    - >55 y: risk of CaP = 1.3% · year
  - 55–69 yr: Shared decision-making if 10–15 yr life expectancy: Do not screen (C)
  - Under age 40 yr: Do not screen (C)
  - 55 yr at higher risk: Individualized decision (C)
  - 55–69 yr: Shared decision-making if 10–15 yr life expectancy: Do not screen (C)
  - >70 yr and <10–15 y: life expectancy: Do not screen (C)
- Other PSA parameters
  - PSA velocity/doubling time
  - PSA density
  - PSA velocity/PSA density

DIAGNOSTIC IMAGING
- No imaging if low risk
- Bone scan: PSA >10 nmol/L or Gleason ≥8
- Pelvic CT and MRI
- Lymph node involvement risk = 10%

Imaging
- 2016 NCCN Guidelines for LCP
  - No imaging if low risk
  - Bone scan: PSA = 10 nmol/L or Gleason ≥8
  - Pelvic CT and MRI
- Imaging: Not indicated for LCP
  - No imaging modality can accurately estimate the extent of tumor and location within or surrounding the prostate

GENERAL MEASURES
- Access life expectancy, overall health status, and tumor characteristics prior to treatment decisions (4)[A]
- Review risk and benefits of all treatments and engage patient in informed decision making process.
- Treatment recommendations based on cancer biology, patient overall health, life expectancy, and preferences.
- Gleason score and tumor stage are predictive of cancer outcomes
- Risk strata are used to develop treatment recommendations (4)[A]
  - Low risk: PSA 10 and a Gleason score of 6 or less and clinical stage T1c or T2a
  - Intermediate risk: PSA 10–20 or a Gleason score of 7 or clinical stage T1b
  - High risk: PSA >20 or a Gleason score of 8 to 10 or clinical stage T2

MEDICATION

First Line
- Primary androgen deprivation therapy (ADT)
  - Rarely indicated for LCP (4)[C]
  - Radiation of symptomatic patients
  - Extensive or poorly differentiated tumors
  - Short life expectancy
- Not recommended by 2014 NCCN Guidelines

Second Line
- Neoadjuvant ADT for surgical treatment
- Not recommended (1)[A]

Difficulties with the treatment of prostate cancer include:
- Highly prevalent disease
- Large population at risk
- Low prevalence of CaP in any one individual
- The long natural history of the disease
- Many competing health issues
- Many treatment options with varying outcomes and side effects
Radiation Therapy

ADDITIONAL TREATMENT

SURGERY/OTHER PROCEDURES

Radical prostatectomy

Radical prostatectomy (RP)

• Removal of prostate gland, seminal vesicles, and anterolateral wall of the urethra

• Sphincter mechanism for continence

• Pelvic lymph node dissection for elevated risk of positive nodes

• Cancer “cure” in truly localized disease

• Option for low, intermediate-risk with 10-yr life expectancy and selected high-risk patients (T1b)

• Similar survival between RP and watchful waiting in low-risk CAP, 65 yr (4B)
**PROSTATE CANCER, LOCALLY ADVANCED (CLINICAL T3, T4)**

Erin M. Burns, MD
James S. Rosof, MD

---

**DESCRIPTION**
- Clinical stage T3 prostate cancer (CaP) refers to disease that is thought to extend outside the prostate and may be palpable or seen on imaging.
- Pathologic stage T3 CaP refers to extracapsular extension (T3a), or tumor invading seminal vesicles (T3b) based on final surgical pathology.
- Clinical stage T4 CaP refers to palpable tumor that is fixed and/or invading adjacent structures.

**RISK FACTORS**

- Incidence of metastases: 10–15%.

**DIAGNOSIS**

**HISTORY**
- Family history of CaP.
- Voids per day: Obstructive/irritative, hematuria.

**VISCERAL EXAM**

- Digital rectal exam (DRE): Note palpable abnormalities, unilateral or bilateral, whether prostate is fixed, any extension of mass into adjacent structures.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- PSA:
  - Value is decreased by 5-ARIs, elevated with instrumentation, infection, larger prostate volume.
- Lab variability: 20–25% (7)[A].

**PSA density:** Serum PSA/prostate volume.
- Sensitivity 48%, specificity 79%, not currently used for routine screening.

**Free PSA (fPSA)**
- Collected via post-DRE urine sample.
- RNA overexpressed in CaP, higher values indicate higher risk of CaP.
- Should be calculated over 18 mo with 3 PSA measurements.

**Bone scan**
- Sensitivity 48%, specificity 79%, not currently used for routine screening.
- May correlate with Gleason score (8).

**PSA velocity**
- Rate of rise of PSA is a specific marker for CaP.
- Should be calculated over 18 mo with 3 PSA measurements.

**PSA level**
- ≥10% is associated with CaP.
- Higher PSA and PSA velocity are associated with higher risk of CaP.

**Diagnostic Procedures/Surgery**

- TRUS biopsy can confirm T3 disease with biopsy of the capsule or SVs.

**TREATMENT**

**First Line**
- Androgen-deprivation therapy (ADT). Option for patients unable or unwilling to undergo surgery or radiation therapy (RT).
- Orchiectomy, luteinizing hormone-releasing hormone (LHRH) agonist or antagonist.
- Can be administered continuously or intermittently; optimal timing of administration is debated.
- More effective when combined in neoadjuvant or adjuvant fashion with RT.

**Second Line**
- Antihormone monotherapy is less effective and not usually recommended; however, side effects are more tolerable overall.

**SURGERY/OTHER PROCEDURES**

- Radical prostatectomy (RP) with pelvic lymph node dissection (PLND).
- Can be performed in a variety of surgical approaches.
- Provides local control and is the preferred treatment for T3 disease.
- Options include open RP, laparoscopic RP, and robotic-assisted RP.

**ADJACENT RT 55–70 Gy improves local control and reduces the risk of biochemical recurrence for T3 disease.**

**DISCUSSION**

- Neoadjuvant ADT does not confer cancer specific or overall survival (OS) benefit.
- Adjunct RT 55–70 Gy improves local control and reduces the risk of biochemical recurrence for T3 disease.
- Neoadjuvant ADT does not confer cancer specific or overall survival (OS) benefit.
PROSTATE CANCER, LOCALLY ADVANCED (CLINICAL T3, T4)

ADDITIONAL TREATMENT

Radiation Therapy

- 70-80 Gy to prostate, 5% and pelvic lymph nodes, or 40-50 Gy and brachytherapy for cT4d disease

- NCCN guidelines recommend 2-3 g necroa/voiding side effects

- Advanced in 3D-conformal, intensity-modulated, and image-guided RT and are designed to deliver higher doses directly to prostate, avoiding adjacent organs and thus limiting side effects

Additional Therapies

- Cryosurgery of the prostate
  - Higher rates of biochemical failure than RT (87% vs. 53%) for T2c-T3 CaP (13A)
  - High-intensity focused ultrasound (HIFU)
  - Currently investigational, may prove to be an option in combination with ADT for intermediate- and high-risk CaP

Complementary & Alternative Therapies

- Consider additional treatment options such as ADT, RT with ADT, or 1-2 yr of ADT

- RT with ADT: OS 72–87% at 5 yr

- Cancer-specific survival (CSS): 85–92% at 5 yr, 79–82% at 10 yr

- RP should include PLND for locally advanced CaP

- Risk of biochemical recurrence increased in:
  - Patients with pathologic T3 disease
  - Patients with positive surgical margins

- Higher rates of biochemical failure than RT (87% vs. 76–82% after radical prostatectomy)

- Higher disease free and OS in men with T3 and T4 disease (12A)

- RT should be administered in conjunction with ADT

- RT should be performed within 4 wk of RP

- RT with ADT: OS 72–87% at 5 yr

Ongoing Care

Prognosis

- Significant risk of progression and death

- Optimum selection criteria for local CaP

- OS without intervention ranges from 10 to 92% at 5 yr and 14–78% at 10 yr for high-grade stage CaP

- RP for T3 CaP: OS 64–96% at 5 yr, 13–72% at 10 yr

- Cancer-specific survival (CSS): 85–92% at 5 yr, 79–82% at 10 yr

- RT monotherapy: OS 60–70% at 5 yr and 50% at 10 yr

- RT with ADT: OS 72–87% at 5 yr

Complications

- Treatment complications are similar to those for localized CaP

- Untreated T3–T4 CaP may lead to hematuria, obstruction at the level of the prostate requiring indwelling catheter or transurethral resection of the prostate, or vesicourethral junction obstruction requiring ureteral stents or percutaneous nephrostomy

Follow-Up

Patient Monitoring

- Periodic PSA measurements, initially at 3-mo intervals posttherapy and then gradually increasing to annually

- Failure of PSA to nadir or consecutive rises in PSA should prompt further evaluation with bone scan and/or CT

- Risk of biochemical recurrence increased in:
  - Gleason score 8–10, PSA doubling time < 10 mo
  - Prostatectomy may be helpful in identifying local recurrence if bone scan and CT scan are negative

- Consider additional treatment options such as ADT, adjunct RT, and/or chemotheraphy and participation in clinical trials

Codas

- ICD9
  - 185 Malignant neoplasm of prostate
  - 198.1 Secondary malignant neoplasm of other urinary organs
  - 198.2 Secondary malignant neoplasm of genital organs

- ICD10
  - C61 Malignant neoplasm of prostate
  - C79.11 Secondary malignant neoplasm of bladder
  - C79.82 Secondary malignant neoplasm of genital organs

Clinical/Surgical Pearls

- Risk assessment requires incorporating serum PSA, clinical stage, Gleason score, tumor volume, and patient age and comorbidities to best provide counseling and treatment recommendations
- RP should include PLND for locally advanced CaP and adjunct RT should be offered for T3–T4 disease, particularly if surgical pathology demonstrates positive margins
- RT should be administered in conjunction with ADT for locally advanced CaP to maximize survival benefit with support from randomized clinical trials.
PROSTATE CANCER, LOCALLY ADVANCED (CLINICAL T3, T4)

PATHOPHYSIOLOGY
- Peripheral zone tumors tend to invade the capsule more often than transition zone tumors
- Tumor spread:
  - T1a (intracapsular invasion) occurs posteriorly and posteriorly by vascular invasion and increases risk of recurrence after RP
  - Tumor volume:
    - Intracapsular invasion is more common in tumors >0.5 cm³ and seminal vesicle invasion is more common in tumors >4 cm³
    - Tumor volume does not independently predict postoperative progression once grade, pathologic stage, and margins are accounted for

ASSOCIATED CONDITIONS
Locally invasive prostate cancer can present with resulting symptoms such as hematuria, obstructive voiding symptoms, and changes in bowel habits

GENERAL PREVENTION
- D’Amico has also suggested a risk stratification into low, intermediate, and high risk groups based on extracapsular extension, seminal vesicle invasion, and surgical margin status predict biochemical recurrence free survival and cancer-specific survival

DIAGNOSIS
HISTORY
- Family history of CaP, race
- Voiding symptoms: Obstructive/irritative, hematuria
- Any bone/back/hip pain or hematuria?

PHYSICAL EXAM
- Digital rectal exam (DRE): Note palpable abnormalities, rectal, levator muscles, or pelvic wall
- Any bone/back/hip pain or hematuria?

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- PSA:
  - Positive predictive value (PPV): 12–32% for PSA >0.75 ng/mL, Gleason score 8 or greater, or a T3/T4 tumor
  - RNA overexpressed in CaP, higher values indicate higher risk of CaP
  - PCA3:
    - Higher PSA density and PCA3 do not correlate with Gleason score or CaP stage
  - PCA3:
    - RNA overexpressed in CaP; higher values indicate higher risk of CaP
    - Collected via post DRE urine sample
    - Sensitivity 48%, Specificity 79%, not currently used for routine screening
    - Recommended to grade with Gleason score

Imaging
- Preoperative imaging for locally advanced cancer:
  - Pelvic CT or MRI is indicated for locally advanced disease (PSA >20 ng/mL, Gleason score 8 or greater, or a T3/T4 tumor) to evaluate for pelvic lymph node involvement
  - Distal metastasis may be ruled out using Technetium 99 bone scan, axial MRI, PET, and immunoscintigraphy

- Multiparametric prostate MRI using a 3T magnet and/or an endorectal coil is being touted to improve accuracy
- Repeat or 1st time staging with bone scan and/or CT may be needed in selected patients who are significantly upstaged and/or upgraded after RP

Diagnostic Procedures/Surgery
Prostate biopsy rarely indicates the presence of pathologic T3 disease; seminal vesical biopsy may confirm T3

Pathologic Findings
- Clinically localized disease is upstaged if pathologic tissue from a prostatectomy indicates T3 or T4 disease
- The risk of cancer recurrence after prostatectomy is based on extracapsular extension, seminal vesicle involvement, lymph node involvement, and correspond most strongly with a positive surgical margin
- A gross PSM carries worse 5y progression survival vs. microscopic margins 65% vs. 40%
- PSA at the bladder neck, vas deferens, and posterolateral surface of the prostate has been shown to have a particularly poor progression-free outcomes in comparison to PSA at the apex, perineum, anterior, or lateral prostate
- With respect to the nerve sparing techniques, when patients are selected appropriately, no statistical difference has been shown in PSA in comparison to the nonnerve sparing technique
NEWER GENERATION ORAL HORMONAL THERAPIES

SECOND LINE

With a median follow-up of 12 yr, (Southwest Cancer Study Group 2009;181:956–962.) Chemo hormonal downstaging trials are ongoing (43% vs. 54%) and overall survival (41% vs. 52%) to early radiation therapy in this pT3 setting (4) for high-risk prostate cancer after RP. The benefit of therapy was observed with or without positive margins (5).

Additional Therapies Protocols to extend external radiation therapy is offered at selected major US centers. However, there is no level I evidence that it is superior to photon-based radiotherapy using an intensity modulated method.

COMPLIANCE & ALTERNATIVE THERAPIES

No level I evidence of benefit

PROGNOSIS

GROWTH WITH A THERAPIES

In the setting of clinical T3/T4 disease, extended lymph node dissection is gaining support in these patients (obturator, external iliac, internal iliac, and presacral nodes) (Accessed May 21, 2014). The American Society of Therapeutic Radiation Oncology (ASTRO) and the American Urologic Association (AUA) have a joint guideline on the use of adjuvant and salvage radiotherapy after prostatectomy (2013;190(2):144–149.).

CODES

ICD10

C79.11 Secondary malignant neoplasm of bladder

C79.82 Secondary malignant neoplasm of genital organs without positive margins (5).

C79.82 Secondary malignant neoplasm of genital organs

C79.99 Secondary malignant neoplasm of unknown primary

PROSTATE CANCER, LOCALLY ADVANCED (CLINICAL T3, T4)

Additional Treatment

Radiation Therapy

If randomized trials have been completed demonstrating a benefit to early adjuvant radiation therapy (346–368.). Treatment is optimally offered after continence is restored, to allow healing to take place after surgery (from biopsy cores) predict more advanced disease at 4 yr after salvage EBRT – Patients with no adverse risk features achieved a 4-progression-free survival probability of 77%. A nomogram based on established risk factors no more accurately identify patient-specific risks to assist in clinical decision-making is available (6).

COMPLICATIONS

– Morbidity from pelvic RT include radiation proctitis, cystitis, incontinence, ED, lymphedema, and stricture disease

– Morbidity from hormone therapy include hot flushes, breast tenderness, osteoporosis, diabetes mellitus, depression, and cardiac disease

FOLLOW-UP

Patient Monitoring

For pT3/T4 after RP, patients are generally followed every 3 mo for the 1st yr, every 6 mo for the next 2–5 yr and yearly thereafter depending on risk.

– PSA, General Considerations

CLINICAL/SURGICAL PEARLS

• Pathologic T3/T4 prostate cancer includes extracapsular cancer than extends beyond the gland, without distant metastasis.

• High clinical stage, PSA levels, and Gleason score (from biopsy core) predict more advanced

• Pathologic staged in 3 RCTs support adjuvant EBRT for high-risk pT3/T4 prostate cancer after RP.

• For patients who do not receive adjuvant EBRT, close follow-up with early salvage EBRT is very commonly practiced.

• There is no level I evidence for adding ADT to EBRT as part of adjuvant or salvage EBRT, but selected high-risk patients may benefit.
PROSTATE CANCER, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)

Divya Ajay, MD
Debasish Sundi, MD
Mioop Han, MD

BASICS

DESCRIPTION
- Metastatic prostate cancer (CaP) can be nodal disease discovered at prostatectomy or on imaging (N+), or can be distant spread (M+). Most commonly, it affects distant lymph nodes and bone.
- The initial presentation or development of previous local therapy for CaP, such as radiation therapy or RP.

EPIEDEMOLOGY
Incidence
With PSA screening, the number of men with metastatic disease at 1st presentation has declined over the last 20 yr (~4%, 2003–2009, SEER data).
Prevalence
Nearly 20,800 men annually (US) from metastatic disease.
RISK FACTORS
- African American ancestry
- High-fat diet
- Family history
Genetics
None

PATHOPHYSIOLOGY
- CaP arises in prostate glandular epithelium and can spread through the lymphatics or hematogenously.
- Bone pain is paravertebral veins that extend up to the vertebral column.
- Testosterone and DHT are the primary regulators of prostate growth.
- 2 sources of androgens in men: testes (95% of total androgens) and adrenal glands (remaining 5%).

ASSOCIATED CONDITIONS
- Osteoporosis secondary to hormonal therapy

GENERAL PREVENTION
- Early androgen blockade for high-risk patients with localized cancer may delay the development of metastatic disease.

DIAGNOSIS

HISTORY
- Urinary symptoms can be indistinguishable from those of BPH and include increased urinary frequency, nocturia, difficulty initiating and maintaining a steady stream of urine, dysuria, and hematuria, and sexual dysfunction.
- The most common symptom of metastatic disease is bone pain, often in vertebral, pelvic, or rib.

PHYSICAL EXAM
- DRE may reveal a nodular or enlarged prostate, but the exam may be unreliable.
- After RP the fossa may be empty or contain palpable recurrent cancer.
- Adrenalectomy may be detected in the supraventricular and inguinal lymph nodes.
- Painful lesions apparent on vertebral bodies or ribs may be indicative of spinal or epidural metastases.

LAB
- Serum PSA should be obtained in all patients prior to the start of therapy and is a useful marker of response to therapy.
- Prostate and phosphatase is elevated in up to 67% of men with metastatic disease.
- Monitor serum testosterone to verify that androgen ablation has testosterone <50 ng/mL.
- CT of the abdomen and pelvis and bone scan should be performed after initial diagnosis. Bone metastases are typically osteoblastic.
- Evaluate for hydronephrosis secondary to ureteral obstruction.

DIFFERENTIAL DIAGNOSIS
- Pelvic disease; bone metastases from other malignancies
- Adrenopathy due to lymphoma or other advanced malignancy

TREATMENT

GENERAL MEASURES
- Androgen blockade for metastatic disease, which is usually considered nontoxic.
- Androgen deprivation therapy (ADT) can be administered continuously as well as intermittently (intermittent hormonal therapy or IHT), studies suggest similar survival when combined androgen blockade (CAB) is compared to intermittent CAB, especially with lower disease burdens.
- ADT using high-dose bicalutamide (150 mg/d), LHRH agonist, and an antiandrogen is associated with >50% of patients with measurable disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC).
- The ECOS2107 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deprivation therapy.

Second Line
- Most patients initially benefit from ADT, but the disease usually progresses after 1–4 yr.
- Castration-resistant CaP (CRPC): Progression on primary hormonal with a testosterone level of <50 ng/mL, and a rising PSA.
- With metastatic disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC).
- Castration-resistant disease usually progresses after 1–4 yr.
- Castration-resistant CaP is a systemic disease and often progresses despite ADT.
- Secondary hormonal therapy is essentially used in CRPC patients without metastases.
- If after ADT, the androgen should be discontinued, this will result in a PSA decline 1–20% of patients.
- Addition of an antiandrogen will result in PSA decline of 50% in 15–54% of patients, with median duration of response 4–6 mo.
- Antiandrogen blockade as initial therapy is associated with >50% of patients.
- Hormone therapy is a systemic approach to CaP.
- Several systemic therapies have demonstrated improved overall survival for metastatic castrate-resistant disease and are discussed in detail in the section on Prostate cancer, rising PSA, following androgen ablation (Castration-Resistant Prostate Cancer (CRPC), and mCRPC). Section II.

Androgen deprivation therapy (ADT)
- ADT to achieve castrate levels of testosterone, generally considered <50 ng/mL, with some advocating <20 ng/mL, similar to orchiectomy levels.
- Testicular androgen secretion is regulated by the hypothalamus, and the pulsatile secretion of luteinizing hormone releasing hormone (LHRH) – LHRH agonists (leuprolide, goserelin, triptoreline) interfere with this pulsatile secretion, and after initial flare (testosterone increase) at 7–10 days, achieve medical castration at about 30 days.
- LHRH antagonists (degarelix) rapidly decrease testosterone levels with 44% testosterone castration (<50 ng/mL) at day 1, 96% by day 3. No flare, so useful in situations such as spinal cord compression.
- Antihormonal (bicalutamide, flutamide, nilutamide) block the LHRH flare reaction initially caused by LHRH agonists and should be used for an immediate chemohormonal therapy (cabazitaxel + LHRH agonists past the flare period, or CAB) is commenced.
- ADT using high-dose bicalutamide (150 mg/d), called antihormone monotherapy, is associated with less side effects but may also be less effective form of ADT and should not be routinely used (not FDA approved in US).
- Initial chemohormonal therapy has recently been reported to extend survival in men presenting with newly diagnosed metastatic prostate cancer (mCRPC).
- ECOS3489 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deprivation therapy.

Second Line
- Most patients initially benefit from ADT, but the disease usually progresses after 1–4 yr.
- Castration-resistant CaP (CRPC): Progression on primary hormonal with a testosterone level of <50 ng/mL, and a rising PSA.
- With metastatic disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC).
- The ECOS2107 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deprivation therapy.

Second Line
- Most patients initially benefit from ADT, but the disease usually progresses after 1–4 yr.
- Castration-resistant CaP (CRPC): Progression on primary hormonal with a testosterone level of <50 ng/mL, and a rising PSA.
- With metastatic disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC).
- The ECOS2107 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deprivation therapy.

Second Line
- Most patients initially benefit from ADT, but the disease usually progresses after 1–4 yr.
- Castration-resistant CaP (CRPC): Progression on primary hormonal with a testosterone level of <50 ng/mL, and a rising PSA.
- With metastatic disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC).
- The ECOS2107 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deprivation therapy.
**PROSTATE CANCER, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)**

**SURGERY/OTHER PROCEDURES**
- Resection of solitary bone metastases is not generally performed with curative intent.
- Decompression of epidural metastases can result in stabilization of the spinal cord and neurologic symptoms. Best results are obtained if the procedure is performed within 24 h of the onset of symptoms.
- Stabilization of weight-bearing bones (femur and hip) by internal fixation or replacement of the joint prophylactically may prevent fracture.
- In one randomized trial, immediate ADT was associated with improved overall and disease-specific survival among men who had pathologically positive lymph nodes after RP [23]. However, this study was limited by sample size and lack of central pathologic review. In a randomized EORTC study with clinically node-positive disease, early ADT did not have any survival benefit. Because of the gradual natural history of CaP (median survival after development of metastasis after RP 5 yr [82] and because the oncologic benefit of early ADT is uncertain, many consider it reasonable to delay ADT until symptoms or measurable disease on imaging are present, to minimize systemic adverse effects of ADT.

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- Radiation can be used to palliate solitary painful bony metastases.
- Strontium$^{89}$ and samarium$^{153}$ ($\alpha$-emitter) can also be used in the setting of symptomatic bone metastasis.

**Additional Therapies**
- **Bone health**
  - Patients should receive calcium (1,200 mg/d) and vitamin D (800–1,000 IU/d) supplements.
  - With ADT, consider zoledronate 4 mg IV yearly, or denosumab—RANK ligand inhibitors; once every 6 mo SQ for men on ADT or Xgeva with bone mets 120 mg SQ q4wk).
- **Antiandrogen withdrawal syndrome** (Flutamide Withdrawal Syndrome)
  - Osteoporosis, obesity, insulin resistance, lipid alteration, and the concern of increased risk of diabetes and cardiovascular disease.
- **Radiation therapy** for CaP is palliative.
- **Bone-marrow ablation** is performed with curative intent.
- **Bone marrow**
  - Ablation (Castration-resistant Prostate Cancer, CRPC) by internal fixation or replacement of the joint is performed within 24 hr of the onset of symptoms.
  - Best results are obtained if the procedure is performed within 24 h of the onset of symptoms.

**COMPLICATIONS**
- ADT: Hot flashes, loss of sexual function and libido, loss of muscle mass, decreased in bone mineral density, weight gain, diabetes, lipid profile changes, and neurocognitive dysfunction.
- In a metaanalysis of 8 randomized controlled trials, long-term ADT was not associated with an increased risk of death from cardiovascular causes, however.
- Antiandrogens: Increased liver function test.
- Skeletal-related events: Defined by pathologic fracture, spinal compression/vertebral body collapse, osteonecrosis of the jaw, radiation or surgery to bone, or change in antihypertensive therapy. Androgen blockade can cause osteoporosis/osteopenia, bisphosphonate/RANK ligand therapy can limit reductions in bone mineral density.
- Zoledronic acid: Renal insufficiency, adjust based on creatinine.
- Osteonecrosis of the jaw can result from bisphosphonates and RANK ligand inhibitors; avoid major dental work (extractions) on therapy; perform oral exam before starting.

**FOLLOW-UP**

**Patient Monitoring**
- Monitoring patients is controversial. With start of ADT or Xgeva with bone mets 120 mg SQ q4wk).
- **Timing of PSA testing** during chemotherapy is controversial; usually every 3 wk.
- **Surveillance** for skeletal-related events: Defined by pathologic fracture, spinal compression/vertebral body collapse, osteonecrosis of the jaw, radiation or surgery to bone, or change in antihypertensive therapy. Androgen blockade can cause osteoporosis/osteopenia, bisphosphonate/RANK ligand therapy can limit reductions in bone mineral density.
- **Monitoring for osteoporosis, obesity, insulin resistance, lipid alteration, and the concern of increased risk of diabetes and cardiovascular diseases** while on ADT should be considered.

**Patient Resources**

**REFERENCES**

**ADDITIONAL READING**

**CODES**
- ICD9
  - 165 Malignant neoplasm of prostate
  - 185.5 Secondary and unspecified malignant neoplasm of lymph nodes of regional and lower limb
  - 198.5 Secondary malignant neoplasm of bone and secondary bone marrow

- ICD10
  - C61 Malignant neoplasm of prostate
  - C77.4 Malignant neoplasm of lymph nodes of regional and lower limb
  - C79.51 Secondary malignant neoplasm of bone

**CLINICAL/SURGICAL PEARLS**
- ADT is the 1st-line treatment for metastatic CaP.
- There are several antiandrogen and chemo-immunotherapeutic options for men with ADT-refractory metastatic CaP.
- Bone-related issues should be considered in this population.
PROSTATE CANCER, POSITIVE MARGIN FOLLOWING RADICAL PROSTATECTOMY

Kiranpreet K. Khurana, MD
Eric A. Klein, MD, FACS

BASICS

DESCRIPTION
- Prostate cancer that extends to the margin of resection upon pathologic analysis of radical prostatectomy specimen
- May be reported as: Focal or extensive, solitary or multiple

EPIDEMIOLOGY

Incidence
- 5–27% for organ-confined prostate cancer (1)
- 17–65% for nonorgan-confined prostate cancer (1)

Prevalence
N/A

RISK FACTORS
- Higher preoperative prostate-specific antigen (PSA)
- Higher clinical stage
- Higher Gleason score
- Higher pathologic stage
- Surgeon experience

Genetics
None directly correlate with positive surgical margin (PSM)

PATHOPHYSIOLOGY

- 3 causes of PSM:
  - Tumor extends beyond prostate to margin of resection
  - Disruption of prostate capsule exposed cancerous glands
  - Artifact from intraoperative manipulation of prostate or pathologic processing

ASSOCIATED CONDITIONS
- Nonorgan-confined prostate cancer: Higher likelihood of PSM compared to organ confined

GENERAL PREVENTION
- Do not dissect too closely at prostatic apex or posterolaterally since PSM frequently seen there
- For radical prostatectomy, choose surgical approach with most familiarity to surgeon

DIAGNOSIS

HISTORY
- History of risk factors (higher PSA, clinical stage, and Gleason grade) may increase chance of PSM

PHYSICAL EXAM
- Digital rectal exam has been shown to be unnecessary if PSA is undetectable

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Monitor PSA at follow-up visits
- In patients with PSM, there is 25–40% chance of subsequent biochemical recurrence (1)

Imaging
- No additional imaging needed after radical prostatectomy for PSM unless there is suspicion of locoregional recurrence or metastatic disease
- Bone scan, pelvic MRI, and/or computer tomography scan may be considered if above suspected (2)
- Indium In 111 ProstaScint is also indicated as a diagnostic imaging agent in postprostatectomy patients with a rising PSA and a negative or equivocal standard metastatic evaluation in whom there is a high clinical suspicion of occult metastatic disease. Limited utility for use in this setting

Diagnostic Procedures/Surgery
- None indicated

Pathologic Findings
- PSM is a pathologic diagnosis
- Most common site is prostatic apex
- Posterior/proximal margin and bladder neck also commonly involved
- Note that capsule is missing at the apex, so PSM at the apex may be artifactual
- Often classified as: Focal or extensive, solitary or multiple
- Extensive and/or multiple PSM increase chance of biochemical recurrence, but these subclassesifications of PSM do not have greater predictive usefulness than comparing positive vs. negative surgical margin alone (1)

DIFFERENTIAL DIAGNOSIS
- Nonorgan-confined disease with extraprostatic extension or locally advanced disease
- Iatrogenic capsular tissue

TREATMENT

GENERAL MEASURES
- Surgical approach (open, laparoscopic, robotic) does not appear to influence rate of PSM (3)
  - Use good surgical principles to avoid PSM
  - PSM vary by different pathologic sectioning
  - Surgical experience decreases size of PSM

MEDICATION
- First Line
  - N/A
- Second Line
  - N/A

SURGERY/OTHER PROCEDURES
- N/A

ADDITIONAL TREATMENT

Radiation Therapy
- External beam, delivered as 3D-conformal or intensity modulated
  - 64–65 Gy usual dose
- Adjuvant radiotherapy shown to decrease biochemical and local recurrence, and clinical progression (2)
- Effect on subsequent metastasis and overall survival not as clear
- Treatment with adjuvant radiotherapy results in lower use of salvage treatment
- Since majority of patients with PSM do not develop clinical recurrence, immediate adjuvant radiotherapy may lead to overtreatment
- However, salvage radiotherapy may not be as effective for high-risk disease
- Controversy over use of immediate vs. salvage adjuvant therapy
PROSTATE CANCER, POSITIVE MARGIN FOLLOWING RADICAL PROSTATECTOMY

Additional Therapies
- Radiation Therapy Oncology Group trial 9601 is investigating radiotherapy with or without long-term androgen deprivation in postprostatectomy men with pT3N0 disease or pT2N0 disease with a positive margin with PSA ≥0.2–4 ng/mL.
  - Preliminary results show that 24 mo of androgen therapy (bicalutamide) and radiotherapy improve biochemical-free survival and incidence of metastatic disease.
  - Full results awaited.
- Radiotherapy and androgen deprivation in combination after local surgery (RADICALS) trial is evaluating immediate adjuvant radiotherapy vs salvage radiotherapy.
  - Also addresses role of androgen deprivation.
  - Results awaited.

Complementary & Alternative Therapies
See “Additional Therapies” above.

ONGOING CARE

PROGNOSIS
- Not all PSM result in biochemical recurrence, nor higher risk of metastatic disease and death, but those with PSM are at higher risk of both than those with negative margins; these risks are associated with other pathologic features as well.
- Prediction tools such as http://nomograms.mskcc.org/ prostatecancer are used at some centers for decision making concerning postradical prostatectomy management.
- Preliminary results with new genomic classifiers may indicate which patients might benefit from adjuvant radiation therapy.

COMPLICATIONS
- Complications related to radiotherapy (2):
  - Grade 1 or 2 acute toxicities: Common, up to 45%.
  - Grade 3 or 4 acute toxicities: Up to 20%.
  - Up to 28% may develop late toxicities.
- Urinary incontinence, stricture more common than gastrointestinal toxicities (rectal).

FOLLOW-UP

Patient Monitoring
- PSA every 3–6 mo for 1st 3–5 yr, then annually thereafter.
- Value ≥0.2 ng/mL after surgery with confirmatory value of ≥0.2 ng/mL defines biochemical recurrence.

Patient Resources

PROSTATE CANCER, RISING PSA FOLLOWING ANDROGEN ABLATION
(CASTRATION-RESISTANT PROSTATE CANCER, CRPC AND mCRPC)
Jianqing Lin, MD
Wm. Kevin Kelly, DO

BASICS

DESCRIPTION
• Castration-resistant prostate cancer (CRPC) is defined as prostate cancer with disease progression despite effective androgen deprivation (serum total testosterone <50 ng/dL).
• CRPC patients are classified as having metastatic disease (Bone or soft tissue visible on imaging) (mCRPC) or nonmetastatic disease (CRPC Rising PSA without any radiographic evidence of metastasis)
• CRPC survival is improved significantly with more effective treatment options.
• Synonymous. The preferred term is castrate-resistant prostate cancer but sometimes called castrate refractory prostate cancer. Older terms such as hormone refractory or androgen-independent prostate cancer are not considered accurate.
• Latest data shows that in CRPC prostate cells are still sensitive to low levels of androgens.

EPIDEMIOLOGY
Incidence
• 233,000 cases of prostate cancer will be diagnosed in the United States in 2014.
• There will be 29,480 deaths due to prostate cancer in 2014.
• The vast majority of patients who die with prostate cancer will die from progressive metastatic CRPC.
• Historically, the median survival with mCRPC is ~2 yr; newer agents, most introduced since 2010, have improved overall survival by several months.

Prevalence
• N/A

RISK FACTORS
• No definitive tool is available to determine the risk of developing CRPC.
• Molecular biomarkers and genetic profiles are being explored for prognostic and treatment.
• CRPC risk factors for poor survival:
  – Low hemoglobin
  – Elevated lactate dehydrogenase
  – Elevated alkaline phosphatase
  – Poor performance status
  – Urinary metastasis particularly liver metastasis
  – Narcotic use for pain
  – Hormone-based on these clinical features can predict overall prognosis for CRPC (1)

Genetics
• Common chromosomal translocations found in CRPC include the TMPRSS2-ERG fusions. Epigenetic abnormalities are common in CRPC

PATHOPHYSIOLOGY
• Androgen receptor (AR) activity is a major driver of therapeutic failure and CRPC development.
• This may occur through intrinsic (intrinsic) androgen synthesis, AR dereguation; AR mutation and alternative splicing, and posttranslational modifications and collective alterations.

ASSOCIATED CONDITIONS
• Fatigue, muscle wasting, incontinent syndrome
• Bone pain/flare
• Hematuria, urinary retention
• Edema
• Spinal cord compression
• Anemia
• Renal failure, usually due to nephrotoxicity
• Cognitive dysfunction

GENERAL PREVENTION
• N/A

DIAGNOSIS

HISTORY
• Prostate cancer history including Gleason score, disease stage at diagnosis, initial treatment for localized prostate cancer.
• Time of 1st diagnosis of metastatic disease
• Past hormonal treatments including time when treatments were started
• PSA history
• Extent of disease at the time of diagnosis and also current extent of disease on the bone and CT/MRI scan
• Recent changes in bowel and urinary habits
• Potency
• New neurologic symptoms
• Past medical history including any specific cardiac, renal, or gastrointestinal disease
• Performance status
• Mental status evaluation
• Current medications and allergies
• Caregiver
• Family history of prostate cancer or other cancers
• Smoking, alcohol, and drug history

PHYSICAL EXAM
• Examine for adrenopathy
• Gynecomastia
• GU and rectal exam
• Extremity edema and swelling
• Neuropsychologic exam with focus on lower extremity weakness and sensation

IMAGING
• Determine presence of radiographic metastasis as a guide to treatment
• Bone scan, CT, or MRI of the abdomen and pelvis at baseline and then every 6–12 mo or based on clinical setting
• Bone density as needed

Differential Diagnosis
• Bone pain may also be due to degenerative joint disease, osteoarthritis, Paget disease, or secondary malignancy
• Weight loss due to depression, other malignancies, or failure to thrive
• Anemia related to iron and vitamin deficiency, secondary malignancy (ie, multiple myeloma), or prior therapies

Pathologic Findings

DIFFERENTIAL DIAGNOSIS
• Bone pain may also be due to degenerative joint disease, osteoarthritis, Paget disease, or secondary malignancy
• Weight loss due to depression, other malignancies, or failure to thrive
• Anemia related to iron and vitamin deficiency, secondary malignancy (ie, multiple myeloma), or prior therapies

TREATMENT

GENERAL MEASURES
• Initial strategies for nonmetastatic CRPC are unclear as no randomized clinical trial has shown survival advantage in the setting of no radiotherapeutically measurable metastatic disease
• Continuing medical castration recommended
• Verify castrate levels of testosterone. If not <50 ng/dL, consider alternative luteinizing hormone-releasing hormone agonist/antagonist administration or orchiectomy if noncastrate
• Define the treatment objectives for patients: Palliative vs. prolonging survival
• Disease progression based on a rapidly rising PSA, objective changes on bone scan or CT/MRI scan or symptoms from the metastatic CRPC
• Sequencing of newer agents in the setting of disease progression remains under study
• AUA, ASCO, NCCN, and other groups have issued guidelines for the management of CRPC

MEDICATION

First Line
• There are multiple treatment options based on disease stability and prior treatment history such as before or after docetaxel-based chemotherapy, clinical trials always need to be considered.
• Often secondary or tertiary hormonal manipulation is the initial therapy in asymptomatic mCRPC. These include:
  – Antiandrogen withdrawal (ie, stopping bicalutamide, etc.)
  – Paradoxical decrease in PSA after stopping
  – 2nd line hormonal therapy with nonsteroidal antiandrogen bicalutamide, flutamide, nilutamide
• Rarely results in a durable response

Second Line
• Immunotherapy with sipuleucel-T: Autologous immunotherapy for minimally symptomatic or asymptomatic mCRPC, improved survival (2)
PROSTATE CANCER, RISING PSA FOLLOWING ANDROGEN ABLATION (CASTRATION-RESISTANT PROSTATE CANCER)

**ONGOING CARE**

**PROGNOSIS**

Median survival of patients with CRPC ranges from 18 to 27 mos depending on the extent of disease.

**COMPPLICATIONS**

- Neurological
- Gastrointestinal
- Lung
- Hematopoietic
- Urological

**SECOND LINE**

- Consider abiraterone or enzalutamide with mCRPC progression if not used previously
- Consider chemotherapy: Cabazitaxel (20–25 mg/m² IV every 3 wks with 10 mg prednisone daily)
- Approved posttaxane
- Mibolerone: chemotherapy FQA approved for palliation; limited utility
- Consider clinical trials

**ADDITIONAL TREATMENTS**

**Surgical Procedures**

- Bladder outlet procedures such as TURP for urinary retention
- Urinary diversion (stents or percutaneous nephrostomy) in cases of hydronephrosis and renal insufficiency

**Radiation Therapy**

- Palliative radiotherapy
- Radium 223 (Alphadurad)
- Palliative bony radiation
- Palliative care or pain specialist referral for refractory pain

**Bone Health**

- Bisphosphonate (zoledronic acid) or denosumab for symptomatic bone metastases
- Daily calcium (1,200 mg/or 1,000 IU daily)
- Vitamin D (800–1,000 IU daily)
- Consider clinical trials

**First-line chemotherapy:** Docetaxel 75 mg/m² IV

**Androgen–androgen receptor axis remains the key survival factor and treatment target for CRPC.**

**Pearls**

- Antihormonal therapies are all effective to improve survival.
- Immunotherapy, chemotherapy, and bone-targeted therapy are all effective to improve survival.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

ICD-10: **C61** Malignant neoplasm of prostate

**ICD-9:** **790.93** Elevated prostate specific antigen [PSA]

**ICD-10:** **C61.9** Malignant neoplasm of prostate

**ICD-9:** **790.93** Elevated prostate specific antigen [PSA]

**Clinical/Surgical Pearls**

- Castration-resistant prostate cancer must be classified as with (mCRPC) or without (CRPC) radiographic metastasis.
- Bone metastases will evolve if not initially present.
- Androgen–androgen receptor axis remains the key survival factor and treatment target for CRPC.
- Androgen receptor targeted therapy, immunotherapy, chemotherapy, and bone-targeted therapy are all effective to improve survival.
PROSTATE CANCER, UROTHELIAL

Eric A. Klein, MD, FACS
Samuel Haywood, MD

**BASICS**

**DESCRIPTION**

- UC described in 1952 by Millicoe and Hollowell—originally noted as Blower’s disease of the prostate urethra (1)
- Can occur in 1 of the 3 forms:
  - Primary urothelial carcinoma (UC) of the prostate
  - Direct extension of bladder UC
  - Nonbudd extension of bladder UC
- Multiple prior staging systems:
  - Primary UC of the prostate—TNM staging 2001
  - To pu—carcinoma in situ (CIS) affecting prostatic urethra
  - T1 pu—CIS affecting prostatic ducts
  - T1 tumor invading subepithelial connective tissue
  - T2 tumor invading prostatic stroma, spongiosum body, perivesical muscle
  - T3 tumor invading perivesical tissue or bladder neck (extraprostatic extension)
  - T4 tumor involving bladder or surrounding organs
- Prostatic UC concurrent with bladder UC
  - Prior TNM staging defined prostatic invasion of bladder UC as T4a disease
  - However, given the heterogeneity of this classification, did not accurately predict survival
  - Most recent TNM classification (2010) clarifies staging workup involves abdominal and chest imaging (CT vs. MRI) to identify local, regional, and extravesical spread
  - Stomal invasion from subvesical invasion of prostatic urethra classified as organ confined disease
  - Synonyms: Transitional cell carcinoma (TCC)

**EPIDEMIOLOGY**

**Incidence**

- All patients with bladder UC undergoing cystoprostatectomy, 12–48% will have prostatic involvement (1)
- However, underreporting of prostatic involvement
- Body present in radical cystectomy specimens
- Prostatic involvement of UC is a predictor of direct extension to the prostate
  - Stomal invasion of the prostate is present in 7–17% of cystectomy specimens (2)
- Primary UC of the prostate is rare malignancy—1.4% of all primary prostatic tumors (3)

**Prevalence**

- N/A

**RISK FACTORS**

- Risk factors for prostatic involvement
  - CIS of the bladder
  - Multifocal disease in bladder
  - High-stage bladder UC
  - Previous involvement of prostate
  - Tumors involving trigone or bladder neck
  - Risk factors for stromal invasion—presence of CIS (odds ratio 3.2) and location of tumor at or below trigone (odds ratio 3.3) (2)

**Genetics**

- Genetics:
  - No specific genes associated with prostatic UC

**PATHOPHYSIOLOGY**

- May involve any part of the prostatic urethra, prostatic duct system, or prostate stroma
- Arises from extension of bladder primary tumor
- Implantation of malignant cells, or transformation secondary to carcinogenic field effect
- Metastases commonly to bone, lung, liver, gastrointestinal tract

**ASSOCIATED CONDITIONS**

- Almost all cases (>95%) associated with bladder UC

**GENERAL PREVENTION**

- Prevention strategies similar as to bladder UC

**DIAGNOSIS**

**HISTORY**

- Risk factors similar to bladder UC—tobacco exposure, chemical/occupational exposures
- Hematuria is the most common complaint
- Other symptoms include obstructive voiding dysfunction, pain, fatigue, weight loss

**PHYSICAL EXAM**

- Hematuria or bloody urethral discharge
- Lymphadenopathy
- Abdominal digital rectal exam

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- PSA: Elevations rare in UC
- Urine studies: Urinalysis, urine cytology

**Imaging**

- Staging workup involves abdominal and chest imaging (CT vs. MRI) to identify local, regional, and distant spread
- Bone scan: UC lesions osteolytic vs. adenocarcinoma (ADC) lesions osteoblastic

**DIAGNOSTIC PROCEDURES/SURGERY**

- Cystoscopy—sensitivity 63.3%, specificity 95.1% (2E)
- Focus on macroscopic disease and concurrent bladder lesions
- Unlikely to find microscopic disease or CIS
- Transurethral biopsy (TUR)
- No clear consensus on timing or methods
- Spectrum of sampling recommended in literature from few resectoscope swipes to complete TURP
- Pathologic analysis shows involvement most frequently observed around verumontanum
- Biopsies recommended if positive cytology and/or macroscopic lesions
- Methods of biopsy have varying accuracy (1E)
- Transurethral resection (TUR) biopsy is most accurate: 90% accuracy
- Fine needle aspiration (FNA) biopsy: 40% accuracy
- Transrectal needle biopsy: 20% accuracy
- Biopsies poor at accurately detecting stromal invasion—sensitivity 53%, specificity 77%, positive predictive value (PPV) 45%
- Diagnosis of primary UC of prostate requires both transurethral biopsy and random biopsies of bladder to exclude concurrent UC in the bladder (2E)

**Pathologic Findings**

- Urothelial tumor in situ (CIS) of the prostate:
  - Can involve the prostatic urethra, the prostatic ducts, and the prostatic acini
- Most prostatic urothelial UC arises along with bladder urothelial neoplasia or from pagetoid spread from the bladder into the prostate
- Partial or complete replacement of urethra or duct by atypical urothelial cells with pleomorphic nuclei, coarse chromatin, and frequent mitoses
- Fibrosis and chronic inflammation may be seen

- Invasive UC into prostatic stroma consists of irregular nests, clusters, or single atypical cells that infiltrate prostatic tissue
- There are 2 distinct pathways that invade the prostate:
  - Invasive carcinoma arising from the prostatic urethra and duct, which is often associated with CIS within the prostatic duct or acini
  - Prostatic stromal invasion, in which bladder cancer penetrates from posterior periprostatic soft tissue or the bladder neck

**IMMUNOHISTOCHEMISTRY**

- Bladder urothelial neoplasia or from pagetoid spread from the bladder into the prostate
- Spectrum of sampling recommended in literature from few resectoscope swipes to complete TURP
- Pathologic analysis shows involvement most frequently observed around verumontanum
- Biopsies recommended if positive cytology and/or macroscopic lesions
- Methods of biopsy have varying accuracy (1E)
- Transurethral resection (TUR) biopsy is most accurate: 90% accuracy
- Fine needle aspiration (FNA) biopsy: 40% accuracy
- Transrectal needle biopsy: 20% accuracy
- Biopsies poor at accurately detecting stromal invasion—sensitivity 53%, specificity 77%, positive predictive value (PPV) 45%
- Diagnosis of primary UC of prostate requires both transurethral biopsy and random biopsies of bladder to exclude concurrent UC in the bladder (2E)

**DIFFERENTIAL DIAGNOSIS**

- High-grade prostatic intraepithelial neoplasia (HGPIN)
- Prostatic adenocarcinoma
- Other uncommon prostatic tumors

**DIAGNOSTIC PROVENCE**

- Prevention strategies similar as to bladder UC
- All patients with bladder UC undergoing cystoprostatectomy, 12–48% will have prostatic involvement (1)
- However, underreporting of prostatic involvement
- Body present in radical cystectomy specimens
- Prostatic involvement of UC is a predictor of direct extension to the prostate
- Stomal invasion of the prostate is present in 7–17% of cystectomy specimens (2)
- Primary UC of the prostate is rare malignancy—1.4% of all primary prostatic tumors (3)
Therapies
Complementary & Alternative

**Recommendations (1)**

**Radiation Therapy**

- Surgery/Other Procedures

  - Options include TUR alone, TUR with BCG (as in "first line" above), and radical cystoprostatectomy
  - Radical cystoprostatectomy is the treatment of choice for stromal-invasive prostatic UC. It should also be recommended for patients with progression or recurrence after nonsurgical therapies. (1,2,5)[C]
  - Evidence regarding depth of penetration of BCG into prostatic stroma is unclear—CIS of prostatic urethra has response rates to BCG of ∼70–100%. Response rate when combined with bladder primary decreases to 47–72% (1)[C].
  - Response rates of bladder CIS of prostatic urethra to BCG immunotherapy is ∼70–100%.
  - Some propose TUR prior to BCG therapy to increase exposure—improved prevention of recurrence compared to TUR alone (1)[C].
  - Absolute contraindications to BCG: Active urinary infection, gross hematuria, traumatic catheterization.

**Second Line**

- Adverse reactions to BCG therapy
  - Adverse reactions include fevers and/or sepsis, and are managed with hospitalization and antibiotics (eg, isoniazid, rifampin, ethambutol, and fluoroquinolones)
  - Local reactions include hematuria, fever, dysuria
  - BCG infectious complications include fever, urinary tract infection, and/or sepsis, and are managed with hospitalization and antibiotics (eg, isoniazid, rifampin, ethambutol, and fluoroquinolones)

**Prognosis**

- Degree of prostatic invasion has prognostic implications with respect to 5-yr survival rates (1)
  - Involvement of the urethral mucosa: 100% survival
  - Ductal/acinar involvement: 50%
  - Involvement of the urethral mucosa: 100% survival
  - Stromal invasion: 40%
  - Ductal/acinar involvement: 50%
  - Involvement of the urethral mucosa: 100% survival

**Additional Reading**

PROSTATE CANCER, VERY LOW RISK AND ACTIVE SURVEILLANCE

Michael A. Gorin, MD
Trinity J. Bivalacqua, MD, PhD

PATHOPHYSIOLOGY
- A combination of genetic, hormonal, and environmental factors underlies the development of PCA.
- >95% of all tumors are adenocarcinoma.
- Other histologic types include transitional cell, small cell, and sarcoma.
- NCCN risk categories and AS only pertain to adenocarcinoma.
- Early-stage adenocarcinoma is androgen dependent. As PCA becomes more advanced, tumors de-differentiate and lose this dependency.
- ~70% of PCs arise from the peripheral zone of the prostate.
- Tumors are often multifocal.

ASSOCIATED CONDITIONS
- Many men with PCs also have benign prostatic hyperplasia (BPH)/lower urinary tract symptoms.
- BPH is not a precursor to PCA.

PATHOLOGIC FINDINGS
- BPH, prostatitis (granulomatous, acute, or chronic), recent instrumentation, nonadenocarcinoma prostate malignancy (sarcoma, urothelial carcinoma)

DIFFERENTIAL DIAGNOSIS
- Localized PCA:
  - BPH, prostatitis (granulomatous, acute, or chronic), recent instrumentation, nonadenocarcinoma prostate malignancy (sarcoma, urothelial carcinoma)

TREATMENT
GENERAL MEASURES
- Adequate patient evaluation and review of all treatment options is essential
- Identification of patients who may be an appropriate candidate for AS

MEDICATION
First Line
- No role for chemotherapy or androgen deprivation for men who are candidates for AS
- S-Adrs do not appear to prevent disease progression of men on AS

Second Line
- NKI
SURGERY/OTHER PROCEDURES

- Radical prostatectomy may be offered to men who desire treatment.
- A pelvic lymph node dissection may be omitted given the low risk of lymph node metastases in this population.
- When open or robotic or laparoscopic surgery is performed, treatment with either intensity-modulated or 3-dimensional conformal radiation therapy should be utilized to limit toxicity to surrounding organs.
- Major side effects of surgery include urinary incontinence and erectile dysfunction.

ADDITIONAL TREATMENT

Radiation Therapy
- External beam radiation therapy or brachytherapy are acceptable alternatives to AS and surgery.
- Adjacent hormonal therapy is not indicated with either approach in this group of men.
- When external beam radiation therapy is performed, treatment with either intensity-modulated or 3-dimensional conformal radiation therapy should be utilized to limit toxicity to surrounding organs.
- Brachytherapy should be avoided in men with symptoms of bladder outlet obstruction (high International Prostate Symptom Score) due to the risk of worsening lower urinary tract symptoms.

- Major side effects of radiation include urinary incontinence, irritative voiding symptoms, erectile dysfunction, radiation induced proctitis, hemorrhagic cystitis and secondary malignancies most commonly of the bladder and rectum.

Additional Therapies
- Technologies for focal and hemi-ablation are currently in the early phases of investigation.
- Modalities include therapy, high intensity focused ultrasound, interstitial laser and cryosurgery.

Complementary & Alternative Therapies
- Low low appropriate recommendation

FOLLOW-UP

Patient Monitoring
- The optimal protocol for monitoring men on AS is unknown.
- Most advocate for biannual PSA measurements with DRE and annual 12–14 core prostate biopsy.
- PSA kinetics do not appear to be helpful in predicting disease progression.
- Monitoring for disease progression is not indicated after age 75 of when life expectancy is <10 yr.

Patient Resources
- The NCCN Guidelines for Patients: Prostate Cancer (http://www.nccn.org/patients/guidelines/prostate/).
- What You Need to Know About Prostate Cancer from the National Cancer Institute (http://www.cancer.gov/cancertopics/wynewsletter/prostate).

- PSA Elevation, General Considerations

PATHOLOGY/BIOLICAL

- PSA kinetics do not appear to be helpful in predicting disease progression.
- Most advocate for biannual PSA measurements with DRE and annual 12–14 core prostate biopsy.

CLINICAL/SURGICAL

- A large percentage of older men with screen-detected PCa will have insignificant tumors and, therefore, not benefit from intervention.
- To avoid the potential morbidity associated with treatment, AS should be offered to men with low–risk PSA and a life expectancy of <20 yr.
- The optimal follow-up protocol is not well defined but typically includes biannual PSA measurements with DRE and annual 12–14 core prostate biopsy.
- PSA kinetics are less useful than biopsy findings for accurately reclassifying men while on AS.
- It is unknown if men reclassified on AS would have been better served with immediate treatment; however, long-term data from a number of centers suggest good oncologic outcomes with this management strategy.
PROSTATE, ABSCESS
Garjae D. Lavien, MD
Michael J. Naslund, MD

BASICS

DESCRIPTION
Prostate abscess is an infection of the prostate with focal accumulation of pus within the prostate gland. It is usually a result of ineffective antibiotic therapy for acute prostatitis, and may occur in nonhospitalized patients.

Epidemiology

Incidence
Decreasing with widespread use of antibiotics.

Prevalence
Diagnosed in 0.2% of patients with urologic symptoms, 0.5–2.5% of patients hospitalized for prostatic symptoms.

RISK FACTORS

Bladder outlet obstruction, history of bacterial prostatitis, chronic hemodialysis, diabetes, etc.

Indwelling catheters
Lower urinary tract instrumentation
Sexually transmitted infections
Lower urinary tract instrumentation
Sexually transmitted infections
Compromised immune system (eg, HIV/AIDS, cancer, diabetes, etc.)
Chronic renal failure, hemodialysis
Cirrhosis
Diabetes
HIV/AIDS

GENERAL PREVENTION

Avoided preventing and treating sexually transmitted infections.

DIFFERENTIAL DIAGNOSIS

Pathologic Findings

Gram stain and culture of material will give causative agent, most commonly bacterial.

MRI

May guide drainage and aspiration

TRUS

Will reveal hypoechoic zones with irregular internal echoes, septations, and indistinct borders

CT

Nonenhancing fluid-density collections that can be multiseptated or non-enhancing lesions.

LAB

Prostate-specific antigen should not be obtained in this setting as it will usually be elevated due to the inflammatory process.

IMAGING

Transrectal ultrasound (TRUS)

Can determine penetration of the abscess into the periprostatic tissues and identify gas within the prostate.

CT findings include nonenhancing fluid-density collections that can be multiseptated or non-enhancing lesions.

MRI

May not be feasible in patients who are critically ill and require acute management.

DIAGNOSTIC PROCEDURES/SURGERY

Transurethral ultrasound (TRUS) with aspiration

Transurethral resection of prostate abscess

Pathologic Findings

Pus and infected material will be expressed from prostate during surgical drainage procedure.

Differential Diagnosis

Chronic prostatitis

Acute prostatitis

Pyelonephritis

Cystitis

Chronic renal failure

DIFFERENTIAL DIAGNOSIS

Chronic prostatitis

Acute prostatitis

Pyelonephritis

Cystitis

Chronic renal failure
Surgery/Other Procedures

Transperineal or transrectal needle aspiration with
- Occasionally the transurethral catheter may block drainage of an acutely inflamed prostate or cause bacteriuria.
- In the setting of extreme discomfort or if the catheter is difficult to pass, a suprapubic punch cystostomy is preferred.

Medication

First Line
- Broad-spectrum IV antibiotic therapy followed by directed therapy after causative organism determined by urine culture or Gram stain/culture of abscess fluid.
- 2nd-generation cephalosporins (cefoxitin, cefmenoxime) or 3rd-generation cephalosporins (ceftriaxone, cefixime, cefditoren pivoxil).
- IV fluoroquinolones.
- Clindamycin for additional anaerobic coverage is recommended.

Second Line
- Vancomycin for coverage of MRSA is suspected.
- 2nd-generation cephalosporins (cefoxitin, cefmenoxime) or 3rd-generation cephalosporins (ceftriaxone, cefixime, cefditoren pivoxil).
- IV fluoroquinolones.
- Clindamycin for additional anaerobic coverage is recommended initially.

- Dose based on renal function.
- After acute phase, continue oral antibiotic regimen based on cultures for up to 4 wk.

Surgey/Other Procedures

- Transperineal or transrectal needle aspiration with US guidance followed by urethral catheter drainage.
- Can be performed using local anesthesia or sedation.
- Higher risk of recurrence of abscess.

- Open incision and drainage through a perineal approach.
- Lithotripsy in patients with penetration of the abscess through the capsule of the prostate or through the levator ani.
- Allows placement of a drain.
- Increased morbidity compared to open perineal or transrectal approaches.
- Suprapubic cystostomy can be used as an adjunct for urinary diversion in patients with urinary retention.

Additional Treatment

Radiation Therapy

- Optional once definitive therapy to confirm that no residual abscess remains.

Complementary & Alternative Therapies

COMPLICATIONS

- May progress to spontaneous fistulization into the urinary bladder, prostatic urethra, rectum, or perineum.
- Urosepsis, and possibly death if diagnosis not made in timely manner.

Follow-Up

- Patient Monitoring: Supportive once definitive therapy performed.
- Once acute events resolve, monitoring focuses on optimizing medical comorbidities and improving voiding symptoms.
- Author recommendation: CT or TRUS 4–6 wk after definitive therapy to confirm that no residual abscess remains.
- Follow-up urine culture recommended.

Patient Resources

Treatments

General Measures

- Initial treatment should focus on broad-spectrum antibiotics, IV hydration, and pain control.
- In the setting of acute urinary retention, a Foley catheter placement can be attempted.
- Occasionally the transurethral catheter may block drainage of an acutely inflamed prostate or cause bacteriuria.
- In the setting of extreme discomfort or if the catheter is difficult to pass, a suprapubic punch cystostomy is preferred.

- Open incision and drainage through a perineal approach.
- Lithotripsy in patients with penetration of the abscess through the capsule of the prostate or through the levator ani.
- Allows placement of a drain.
- Increased morbidity compared to open perineal or transrectal approaches.
- Suprapubic cystostomy can be used as an adjunct for urinary diversion in patients with urinary retention.

Additional Treatment

Radiation Therapy

- Optional once definitive therapy to confirm that no residual abscess remains.

Complementary & Alternative Therapies

Reference

Additional Reading

- See Also (Topic, Algorithm, Media)
  - Prostatitis, Acute, Bacterial (NIH I)
  - Urinary Tract Infection (UTI), Adult Males
  - Urosepsis

ICD Codes

- 509.0 Bladder neck obstruction
- 509.1 Acute prostatitis
- 601.2 Abscess of prostate

Clinical/Surgical Pearls

- Prostate abscess is uncommon and thus often overlooked in the differential diagnosis.
- Prostate abscesses in patients presenting with fever and persistent lower urinary tract symptoms that do not respond to antibiotics.
- A pelvic CT scan is generally the best test to evaluate for the possibility of a prostate abscess.
- A delay of antimicrobial therapy in the management of acute bacterial prostatitis can increase the risk of prostatic abscess.
PROSTATE, BENIGN HYPERPLASIA/HYPERTROPHY (BPH)
Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

Benign prostatic hypertrophy (BPH) refers to histologic changes within the prostate gland.

– May not imply the presence of an enlarged prostate or symptoms.
– LUTS are not manifestation of BPH.
– Synonym(s): Nodular hyperplasia

Definitions from the International Continence Society (ICS):

– Benign prostatic hyperplasia is a term used (and reserved for) the typical histologic pattern which defines the disease.
– Benign prostatic obstruction is a form of bladder outlet obstruction (BOO) and may be diagnosed when the cause of outlet obstruction is known to be benign prostate enlargement, due to histologic benign prostatic hyperplasia.
– Benign prostatic enlargement (BPE) is defined as prostate enlargement due to histologic benign prostatic hyperplasia. The term “prostatic enlargement” should be used in the absence of histologic pathology.

EPIDEMIOLOGY

Incidence

– 10% of men >40 will develop histologic evidence of BPH.
– 50–75% of these men will develop bothersome LUTS (1)

Prevalence

– Histologic prevalence of BPH increases with age:
  – 10% to men in their 30s
  – 20% to men in their 40s
  – 50–60% to men in their 60s
  – 80–90% to men in their 70s and 80s

– Men with significant prostate enlargement (>50 cc) 3.5 times more likely to have moderate-to-severe LUTS (2)

– BPH is a histologic diagnosis that does not always result in clinical LUTS

RISK FACTORS

– Although family history and advancing age are risk factors for BPH, evidence for comorbidity, environmental, dietary, or lifestyle-related risk factors are generally weak.

Massachusetts Male Aging Study: Cigarette smoking and increased physical activity protective against BPH; heart disease correlated with development of BPH. Possible association between obesity and prostate volume/LUTS.

Genetics

Some men with younger age of onset and larger glands have a family history of BPH.

PATHOPHYSIOLOGY

– Detrusor response to increased resistance is to generate higher pressures to overcome the outlet resistance. Leads to a variety of cellular and morphologic changes in the bladder. Causes the common storage symptoms of frequency, urgency, and nocturia.

– May lead to bladder decompensation, in which the bladder is no longer able to generate sufficient pressures to empty.

– Primary androgen-dependent growth process involves perineural and transition zones of the prostate.

ASSOCIATED CONDITIONS

– GDM (diabetic bladder defined as urinary frequency, urgency, nocturia, urge incontinence)
– Sexual dysfunction (erectile and/or ejaculatory dysfunction)

GENERAL PREVENTION

– Randomized clinical trials (MtCnTIP) suggested that the combination of an α-blocker with a 5α-reductase inhibitor (5-ARI) can reduce the lifetime risk of acute urinary retention and may prevent symptomatic disease progression in men with enlarged prostate volume (>25 cc) (3).

– Bladder decompensation may be prevented by treatment of BOO.

DIAGNOSIS

HISTORY

– Focus on identifying the presence of LUTS

– Voiding symptoms (previously called obstructive symptoms): Hesitancy, intermittency, weak stream, abdominal straining to void, postvoid dribbling, incomplete emptying, double voiding

– Storage symptoms (previously called irritative symptoms): Daytime frequency, nocturia, urgency, urge incontinence, dysuria, dribbling

– Identify other contributing factors to LUTS

– Medications (ie, diuretics, cold medications)
– Comorbidities (ie, diabetes, multiple sclerosis, Parkinson)

– Previous interventions/therapies

– Family history

– IPSI is a reproducible, validated index designed to determine disease severity and response to therapy:
  – Scores of 0–7, 8–19, and 20–35 signify mild, moderate, and severe symptoms, respectively.

– Equivalent to AUASI with the addition of a quality of life (QOL) score

PHYSICAL EXAM

– Evaluation of the abdomen, pelvis, perineum
– Examine external genitalia
– DRE to estimate prostate size and detect any nodularity suggestive of prostate cancer.
– Anal sphincter tone and sensation should be noted
– Focused neurologic exam on the anus and lower extremity motor and sensory function. A more extensive neurologic exam is indicated for patients with possible neurogenic lower urinary tract dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Lab

– PSA:
  – May be a proxy for prostate size
  – PSA of 1.5 ng/ml correlates with prostate volume ~30 mL in most men (4)
  – Information about potential benefits of PSA screening warranted

Imaging

– Not indicated unless there is evidence of upper tract obstruction or a need to further evaluate hematuria
– TRUS may be beneficial in determining accurate size prior to surgical intervention

Diagnostic Procedures/Surgery

– Uroflowmetry is a simple noninvasive urodynamic measurement in which a patient voids into a device that measures the volume/time of urine flow:
  – Combined with a measurement of PVR (post void residual) volume (see next heading below), it is an excellent screening tool for BPH in men with LUTS

– Uroflowmetry measures voided volume, voiding time, average flow rate, and maximum flow rate (Qmax), also called the PFR.

CT Scan:

– Former: The single best measurement obtained by this study to assess voiding dysfunction. While formal definitions vary, in general with a voided volume of 125–150 mL, a Qmax of >15 mL/s is often considered normal, whereas a value of ≤7 mL/s is suggestive of significant obstruction.

– May need urodynamics to differentiate BOO from hypercontractile bladder (pressure flow study).

– Observation confirmed with low flow (Qmax <15 mL/s) and high voiding pressure >40 cm water.

– PI-RADS: Although generally used, PI-RADS does not convincingly correlate with the severity of LUTS, the presence of BOO, or treatment outcomes:

– Voids to evaluate for occult polyuria or polydipsia.

– Cystoscopy not essential unless there is concern for malignancy, obstruction due to foreign body, or stricture. May be useful to evaluate for most appropriate surgical or minimally invasive treatments.

Pathologic Findings

– Varying degrees of glandular and stromal nodular hyperplasia (as such, hypertrophy is a misnomer).

– The glandular component is made up of small and large acini lined by basal and secretory cells. The stromal component is rich in smooth muscles.

– Nodular growth is a major histologic component of BPH.

– Diffuse stromal infiltration of plasma cells and lymphocytes can be seen, but no infectious agent nor clinical diagnosis of prostatitis is typically present.
DIFFERENTIAL DIAGNOSIS
- Obstructive symptoms: Bladder outlet dysfunction, neurogenic bladder, pelvic floor dysfunction, prostate cancer, prostatic abscess, prostatic syndrome, urethral obstruction (stricture, constrictions)
- Irritative symptoms: Bladder cancer, detrusor hyperreflexia/OAB, interstitial cystitis, pelvic congestion, prostatic syndrome.

TREATMENT

GENERAL MEASURES
- Directed at OAB, unless evidence of significant damage to urinary tract from obstruction (hydrothorax, bladder calculus, recurrent infections)
- Guidelines suggest watchful waiting for men with mild symptoms (IPSS <7) or for more severe symptoms if they are not bothersome to the patient. Simple behavior modification (fluid restriction, decreased alcohol/caffeine) may help
- Medical therapy considered 1st-line by most, but usually requires continuous therapy to maintain benefit
- α-Blocker and 5-ARIs often prescribed together

MEDICATION

First Line
- α-Blockers (reduce muscle tone in prostate/bladder neck): Tamsulosin (0.4 mg to max 0.8 mg)
- α-Blockers (reduce muscle tone in prostate/bladder neck): Silodosin (8 mg/d)
- α-Blockers (reduce muscle tone in prostate/bladder neck): Alfuzosin (10 mg/d)
- α-Blockers (reduce muscle tone in prostate/bladder neck): Tamsulosin (start 0.4 mg to max 0.8 mg)
- α-Blockers (reduce muscle tone in prostate/bladder neck): Doxazosin (start 1 mg/d to max 8 mg; XL form: 2.5 mg)

Second Line
- Nonselective α-blockers: Dutasteride (0.5 mg)
- Selective α1-blockers (reduce muscle tone in prostate/bladder neck): Bicalutamide (5 mg)

Additional Therapies
- Phosphodiesterase-5 inhibitors: Tadalafil (2.5–5 mg/d)
- Phosphodiesterase-5 inhibitors: Silodosin (8 mg/d)
- Phosphodiesterase-5 inhibitors: Alfuzosin (10 mg/d)
- Phosphodiesterase-5 inhibitors: Tamsulosin (start 0.4 mg to max 0.8 mg)
- Phosphodiesterase-5 inhibitors: Doxazosin (start 1 mg/d to max 8 mg; XL form: 2.5 mg)

COMPLICATIONS
- Symptoms usually well managed by medications
- Prostate cancer, when risk factors identified, can be well managed
- Progressive disease, when risk factors identified, can be well managed
- Incontinence, erectile dysfunction, ejaculatory dysfunction are most common side effects
- 5-ARIs block intracellular DHT conversion; generally best for large glands, may take 6–12 mo for improvement
- Dutasteride (5 mg)
- Dutasteride (0.5 mg)

PROGNOSIS
- Symptoms usually well managed by medications
- Prostate cancer, when risk factors identified, can be well managed
- N/A

FOLLOW-UP
- Periodic monitoring depends on severity of symptoms
- Monitor response to therapy with history, AUA SS, PVR, flow rate
- Upper tract imaging and measurement of renal function if elevated PVR (>300 cc)

SURGERY/OTHER PROCEDURES
- Open simple prostatectomy usually for glands >100 g
- Transurethral resection of prostate: useful for causing problems such as very large bladder calculi or to repair diverticulum
- Retroperitoneal simple prostatectomy: Excision of adenoma through incision in anterior prostate commissure
- Open simple prostatectomy: Excision of adenoma through incision in anterior prostate commissure
- Many minimally invasive alternative surgical procedures: Microwave and water-induced hyperthermia, transurethral needle ablation, laser vaporization (contact, noncontact, interstitial, diode), laser prostatectomy (hulium, KTP)

ADDITIONAL TREATMENT
- Radiation Therapy

ADDITIONAL READING
- See Also (Topic, Algorithm, Media)

PROSTATE, BENIGN HYPERPLASIA/HYPERTROPHY (BPH)
**PROSTATE, CALCULI**

Christopher Amling, MD, FACS
Nicholas Cowan, MD

---

### BASICs

**DESCRIPTION**
- Prostatic calculi are extremely common and rarely symptomatic.
- Most stones are discovered incidentally.
- Treatment typically reserved for severely symptomatic men.
- Stones within the prostatic urethra rare and likely due to bladder or upper tract stones that become trapped in the prostatic urethra.
- Reports of calculi in the prostatic urethra following transurethral resection of the prostate.

**EPIDEMIOLOGY**

**Incidence**
- 7% in pathologic specimens.
- 20% in autopsies.
- 30% in radiologic studies, with higher percentages in ultrasound scan exams.

**Prevalence**
- Small areas of microcalcification can be seen in 2nd and 3rd decades of life.
- Almost all men (99%) have some degree of prostatic calcification noted at autopsy.
- Stone burden and size typically increase as a man ages.

**RISK FACTORS (1)**

- **Intraprostatic calculi**
  - Recurrent urinary tract infections (UTIs).
  - Pelvic radiation (for prostate cancer).
  - Studies are mixed on role of inflammation in stone development.
- **Stones within the prostatic urethra**
  - Urolithiasis.
  - Enlarged prostatic utricle.
  - History of transurethral resection of the prostate.

**GENETICS**
- N/A

---

### PATHOPHYSIOLOGY

- Urinary intraprostatic reflux implicated in stone formation.
- Intraprostatic calculi presumed to form by the precipitation of prostatic secretions and calcification of the corpora amylacea under inflammatory conditions.
  - Impaction of prostatic secretions within the prostatic ducts.
  - Concentric layering of calcium phosphate and calcium carbonate on inspissated core result in growth.
  - Stone elements may contain constituents found only in urine and not in prostatic secretions.
  - Stones may harbor bacteria and serve as source for relapsing UTI.
  - For prostatic utricle stones, prostatic utricle distends during voiding and then passively drains.
  - Impaired emptying results in urinary stasis stone formation. Patients present clinically with chronic UTI, hematuria, urethral discharge, epididymitis, and voiding dysfunction.

**ASSOCIATED CONDITIONS**

- Chronic pelvic pain syndrome.
- Prostatitis.
- No association between prostate calculi and risk of prostate cancer.
- Hypospadias (enlargement of the prostatic utricle, a Mullerian duct remnant).

---

### DIAGNOSIS

**HISTORY**

- Typically stones are asymptomatic.
- Evaluate for history of lower urinary tract symptoms (LUTS) (2).
- Presence of large calcui associated with moderate LUTS.
- 25–47% of men with chronic pelvic pain have significant prostatic calcifications.
- Correlation seen with stone size, not number.
- Prostatitis history.
- With prostatic utricle stones patients typically present with chronic UTI, hematuria, urethral discharge, epididymitis, and voiding dysfunction.

**PHYSICAL EXAM**

- Genitourinary exam including DRE.
  - DRE unlikely to localize stones.
- Presence of hypospadias.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- **Urine culture**
  - Escherichia Coli, enterococci, and Klebsiella spp. more common.
- **Expressed prostatic secretions**
  - May see increased leukocytes.
- **PSA optional**
  - PSA levels not influenced by presence or volume of prostatic calculi, but infection related to chronic nids may falsely elevate PSA (3).

**Imaging**

- Stones often identified incidentally.
- Transrectal ultrasound (TRUS).
  - Highly sensitive for large calculi.
- Sometimes seen on plain film.
Diagnostic Procedures/Surgery
- Postvoid residual (PVR)
- Uroflow if significant obstructive voiding symptoms present
- If intraurethral stones are suspected, cystoscopy is diagnostic

Pathologic Findings
- Majority of calculi are found in the posterior and posterolateral zones of the prostate
- Rare to find large stones obstructing the urethra

DIFFERENTIAL DIAGNOSIS
- Benign prostatic enlargement (BPE)
- Calcified prostatic utricle cyst or utricle stone
- False prostatic calculi: Calculi trapped in dilated prostatic urethra or in dilated prostatic utricle
- Prostate cancer
- Prostatitis
- Seminal vesical calculi
- UTI

TREATMENT

GENERAL MEASURES
Evaluate and treat coexisting conditions such as UTI, prostatitis, and BPO

MEDICATION
First Line
Culture-directed antibiotic therapy if urine culture positive

Second Line
TBA

SURGERY/OTHER PROCEDURES
- Surgery rarely indicated and is typically for severely symptomatic patients
- Transurethral resection of the prostate
- Stone burned usually visible on TRUS
- Open prostatolithotomy for large stones
- Cystoscopy with lithotripsy for stones within the prostatic urethra or prostatic utricle

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Excellent, as majority of stones are asymptomatic

COMPICATIONS
- Rarely results in urinary obstruction
- May predispose to chronic UTI

FOLLOW-UP
Patient Monitoring
- No follow-up necessary for asymptomatic incidentally identified stones
- Consider postoperative PVR or uroflow if surgical intervention undertaken

Patient Resources
N/A

CLINICAL/SURGICAL PEARLS
Prostate calculi are very common and rarely require treatment.
PROSTATE, NODULE
Gurdarshan S. Sandhu, MD
Gerald L. Andriole, MD, FACS

BASES

DESCRIPTION
A prostate nodule is usually described as a palpable lesion detected on digital rectal exam (DRE) raise concern for prostate cancer (CaP).
- Nodules can be described as soft, rubbery, firm, hard, or rock hard.
- Nodules can be well circumscribed or irregular and diffuse.
- A normal prostate is about the size of a chestnut and has a consistency similar to that of the contracted thresem. It expanse of the thumb.
- This can be simulated by opposing the thumb to the little finger and palpating the contracted muscle.
- Consistency of nodule can denote underlying pathology.
- Rapidity of appearance and changes in size and consistency can infer malignant potential.
- Nodule detection by DRE is recommended as part of prostate cancer detection programs.
- Current recommendations from the American Cancer Society are, if men decide to be tested for prostate cancer, they should have the PSA blood test with or without a rectal exam.

EPIDEMIOLOGY
Incidence
- Prostate nodule as an isolated finding with normal PSA is found in ~10% of cases of prostate cancer in the US.
- Increasingly men are being diagnosed with prostate cancer based on an elevated serum prostate-specific antigen (PSA) and not an abnormal DRE (50% of diagnoses in 2002) (1).
- 80% of men diagnosed with prostate cancer in 2004–2005 have localized disease (CT1 or CT2) (2).
- 5–10% of men in screening programs have abnormal/suspicious DRE.

RISK FACTORS
- Prostate cancer:
  - Nodule that changes in consistency and size over time
  - Elevated serum PSA (>2.5–4 ng/mL)
  - Positive family history
  - Benign nodules
  - No significant change over time
  - Nodule may be softer
  - Prior episodes of prostatitis, biopsy, or prostate surgery (transurethral resection)
- Prior therapy with intravesical Bacillus Calmette–Guérin (BCG)
- Granulomatous nodules can be due to infectious causes (eg, tuberculosis [TB]) or systemic granulomatous diseases

GENETICS
See “Prostate Cancer, General Considerations”

PATHOPHYSIOLOGY
- Normal prostate has a soft, uniform consistency.
- Prostate enlarges with age.
- Microscopically, nodular prostastic hyperplasia consists of nodules of glands and intervening stroma. May occasionally form benign palpable nodules.
- Nodule can be subjectively graded by degree of firmness/hardness (grades 1–3).
- CaP has to have a volume of 0.7 ml or larger to be detected by DRE.

ASSOCIATED CONDITIONS
- Prostate adenocarcinoma
- Benign prostatic hyperplasia (BPH)
- History of intravesical BCG for bladder cancer

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- History of lower urinary tract symptoms
  - Irritative voiding symptoms
  - Obstructive voiding symptoms
- Fever
- Obstructive voiding symptoms
- Irritative voiding symptoms
- History of intravesical BCG for bladder cancer
- History of intravesical BCG for bladder cancer
- History of intravesical BCG for bladder cancer
- History of intravesical BCG for bladder cancer
- History of intravesical BCG for bladder cancer

PHYSICAL EXAM
- DRE:
  - Carcinoma (prostatic or urothelial cell carcinoma)
  - Firm, indurated nodules within the prostate gland
  - Prostate cancer most often arises in the posterior peripheral zone of the prostate
  - Advanced prostate cancer can make the entire gland firm and cause obliteration of the median and lateral line
- Advanced cancer can also extend into the seminal vesicles or toward the side wall laterally

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - PSA—Serum levels vary with age, race, and prostate volume
  - Improvement in the positive predictive value of DRE for cancer
  - No cut-off value below which the absence of prostate cancer can be guaranteed
  - Risk of prostate cancer is continuous as PSA increases (3).
  - See “PSA Elevation, General Considerations” for further specifics on PSA.
- Urinalysis:
  - Variable findings in men with abnormal DRE; sterile pyuria in granulomatous prostatitis
  - Urethral cytology can be positive in urothelial cancer
- Imaging:
  - Transrectal ultrasound (TRUS):
    - Classic appearance of prostate adenocarcinoma is a round or oval hypoechoic lesion located in the peripheral zone
    - Not very sensitive as 39% of tumors can be missed
    - Also nonspecific as granulomatous lesions can be hypoechoic
    - BPH can have variable appearance
  - Distinguishable from prostate cancer only by biopsy
- Abdominal computed tomography (CT) or magnetic resonance imaging (MRI)
- Bone scan to detect bone metastases in patients with high-risk prostate cancer
- Bone scan to detect bone metastases in patients with high-risk prostate cancer
- Bone scan to detect bone metastases in patients with high-risk prostate cancer
- Bone scan to detect bone metastases in patients with high-risk prostate cancer

PREVALENCE
5–10% of cases of prostate cancer in the US.

BASICS
**DIAGNOSTIC PROCEDURES/SURGERY**

TRUS-guided biopsy (4)
- Used to widely sample the prostate during biopsy in men with an elevated PSA and/or abnormal DRE
- Modern biopsy schemes have modified the standard sextant biopsy scheme to focus on lateralized cores
- Generally 12 cores

Cytoscopy
- Used to evaluate bladder outlet obstruction and hematuria when present

Pathologic Findings

See “Prostate Cancer, General Considerations”

**DIFFERENTIAL DIAGNOSIS**

- Neoplasms, malignant
  - Prostate adenocarcinoma
  - Other prostate malignancies
  - Sarcoma
  - Small cell carcinoma
- Other rare tumors and metastasis
  - Urothelial carcinoma
  - BCG related or other cause
- Urinary retention
  - BPH
- Calculus
- Benign prostatic hyperplasia
- Granulomatous prostatitis
- Urinary tract infection or sepsis
- Granulomatous prostatitis
- Urinary tract infection or sepsis
- Urinary retention

**TREATMENT**

**GENERAL MEASURES**

- Abnormal DRE is an indication for TRUS-guided biopsy of the prostate
- Workup includes assessment of PSA
- Staging investigations including bone scan, CT, and/or MRI are reserved for high-risk cases as dictated by PSA, Gleason score, and DRE

**MEDICATION**

**FIRST LINE**

Antibiotics may be required for infectious causes of prostatitis or TB

**SECOND LINE**

Antibiotics may be required for infectious causes

**SURGERY/OTHER PROCEDURES**

See “Diagnostic Procedures/Surgery” above

**ADDITIONAL TREATMENT**

This is dictated by the results of the TRUS biopsy and presence/extent of prostate cancer

**RADIATION THERAPY**

While not a specific treatment of the nodule, it can be used as primary therapy or as additional adjuvant/salvage therapy after prostatectomy in patients with prostate cancer

**ADDITIONAL THERAPIES**

May be required in cases with metastatic disease or disease that recurs after definitive local therapy

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

N/A

**ONGOING CARE**

Depends on diagnosis after TRUS-guided biopsy

**PROGNOSIS**

- TRUS-guided biopsy
  - Hematuria
  - Hematospermia
  - Urinary tract infection or sepsis
  - Urinary retention

Other complications are dictated by the treatment received for prostate cancer

**FOLLOW-UP**

Patient Monitoring

- Negative biopsy in a patient with an abnormal DRE or elevated PSA requires follow-up with serial PSA and DRE

**PATIENT RESOURCES**

**REFERENCES**

**ADDITIONAL READING**

- Prostate Cancer, General Considerations
- Prostate Cancer, Localized (T1, T2)
- Prostate Cancer, Urthelial
- Prostate Nodule, Image @
- Prostatic, Granulomatous
- Tuberculosis, Genitourinary, General Considerations

**CODES**

- ICD9 = 790.93 Elevated prostate specific antigen (PSA)

- ICD10 = C61.3 Male prostate without lower urinary tract symptoms

**CLINICAL/SURGICAL PEARLS**

- A firm prostate nodule generally deserves further workup with a serum PSA and prostate biopsy
- Up to 40% of patients may develop granulomatous prostatitis after intravesical BCG that may present as a prostate nodule.
PROSTATIC INTRAEPITHELIAL NEOPLASIA (PIN)

Joseph C. Klink, MD
Eric A. Klein, MD, FACS

**BASICS**

**DESCRIPTION**
- Prostatic intraepithelial neoplasia (PIN) describes cytologically atypical cells confined within architecturally benign prostatic glands and acini.
- Historically subclassified—Low-grade PIN (LGPIN) and high-grade PIN (HGPIN)
- PIN 1, 2, or 3
- LGPIN no longer reported because not reliably distinguished from benign prostatic by pathology
- LGPIN carries no increased risk of prostate cancer (PCA) on future biopsies
- HGPIN, and atypical small acinar proliferation (ASAP) are both considered by most to be premalignant
- Antiquated names for PIN include intraductal large acinar atypical hyperplasia, marked atypia, ductal-acinar dysplasia
- Remnant of this chapter will focus on HGPIN

**ASSOCIATED CONDITIONS**
- PIN 1, 2, or 3
- With modern 12-core biopsies, a single focus of HGPIN does NOT increase the risk of PCA diagnosis on subsequent biopsy
- Multifocal HGPIN Predicts Increased Risk of PCA on repeat biopsy
- Historically, HGPIN on prostate biopsy often represented failure to sample a nearby PCA (2)
- The number of cases routinely sampled at prostate biopsy increased, the predictive value of HGPIN for PCA decreased
- With modern 12-core biopsies, a single focus of HGPIN does NOT increase the risk of PCA diagnosis on subsequent biopsies
- Decision for repeat prostate biopsy should be made on other clinical factors (elevated PSA, high PSA-velocity, new nodule on DRE) not influenced by the presence of 1 focus of HGPIN
- Multifocal HGPIN indicates higher risk of PCA on repeat biopsy (3)
- Multivariate odds ratio 3.2 for increased cancer detection with multifocal HGPIN
- 16–75% (usually around 30%) PCA rate on repeat biopsy for multifocal HGPIN
- Repeat biopsy usually done 1 yr after initial biopsy

**PREVENTION**
- Dutasteride reduced the incidence of HGPIN from 6–3.7% in the REDUCE trial
- Finasteride daily for 7 yr decreased the incidence of PIN but are not FDA approved for this use
- Dutasteride daily for 7 yr decreased the incidence of HGPIN from 7.1–6% in the Prostate Cancer Prevention Trial
- Dutasteride reduced the incidence of HGPIN from 6–3.7% in the REDUCE trial
- The risk posed by unifocal HGPIN to a patient’s health and life in the absence of PCa is so low that prevention is not indicated

**PATHOPHYSIOLOGY**
- HGPIN may be precursor of PCA (1)
- PCs can develop without HGPIN
- HGPIN extent and frequency greater when PCs present
- Usually in peripheral zone
- Often multifocal

**HISTORY**
- HGPIN produces no symptoms

**DIAGNOSIS**

**PHYSICAL EXAM**
- Digital rectal exam (DRE) is usually normal, but may reveal a prostate nodule or induration
- No other physical exam findings

**DIAGNOSTIC TESTS & INTERPRETATION**
- Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
- Indicated to look for PCA. HGPIN is an incidental finding

**Pathologic Findings**
- Characterized by proliferation of secretory cells with significant architectural change within prostate glands and acini
- Secretory cells are enlarged with increased nuclear/cytoplasmic ratio and prominent nucleoli
- Cytoplasm of the HGPIN cells stains positively for α-reductase inhibitors
- Cytokines of the HGPIN cells tend to stain positively for α-reductase inhibitors and nuclear protein p63
- Most of these features are shared by PCs
- In PCs, basal cells are absent. In HGPIN the basal cell layer is retained although is often discontinuous on H&E stain (Figure 2)
- Transrectal ultrasound-guided biopsy of the prostate

**DIAGNOSIS**

**HISTORY**
- HGPIN produces no symptoms

**PHYSICAL EXAM**
- Digital rectal exam (DRE) is usually normal, but may reveal a prostate nodule or induration
- No other physical exam findings

**DIAGNOSTIC TESTS & INTERPRETATION**
- Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
- Indicated to look for PCA. HGPIN is an incidental finding

**Pathologic Findings**
- Characterized by proliferation of secretory cells with significant architectural change within prostate glands and acini

- Most of these features are shared by PCs
- In PCs, basal cells are absent. In HGPIN the basal cell layer is retained although is often discontinuous on H&E stain (Figure 2)
- Transrectal ultrasound-guided biopsy of the prostate

**DIAGNOSIS**

**HISTORY**
- HGPIN produces no symptoms

**PHYSICAL EXAM**
- Digital rectal exam (DRE) is usually normal, but may reveal a prostate nodule or induration
- No other physical exam findings

**DIAGNOSTIC TESTS & INTERPRETATION**
- Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
- Indicated to look for PCA. HGPIN is an incidental finding

**Pathologic Findings**
- Characterized by proliferation of secretory cells with significant architectural change within prostate glands and acini
- Secretory cells are enlarged with increased nuclear/cytoplasmic ratio and prominent nucleoli
- Cytoplasm of the HGPIN cells tends to stain positively for α-reductase inhibitors and nuclear protein p63
- Most of these features are shared by PCs
- In PCs, basal cells are absent. In HGPIN the basal cell layer is retained although is often discontinuous on H&E stain (Figure 2)
- Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
- Indicated to look for PCA. HGPIN is an incidental finding

**Pathologic Findings**
- Characterized by proliferation of secretory cells with significant architectural change within prostate glands and acini
- Secretory cells are enlarged with increased nuclear/cytoplasmic ratio and prominent nucleoli
- Cytoplasm of the HGPIN cells stains positively for α-reductase inhibitors and nuclear protein p63
- Most of these features are shared by PCs
- In PCs, basal cells are absent. In HGPIN the basal cell layer is retained although is often discontinuous on H&E stain (Figure 2)
- Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
- Indicated to look for PCA. HGPIN is an incidental finding
**Differential Diagnosis**
- Prostate Cancer (PCa)
- ASAP
  - Confers an increased risk of subsequent PCa diagnosis
  - Requires repeat prostate biopsy in a few months to rule out PCa
- Normal anatomic structures and embryonic rests
- Atypia induced by inflammation, infection, or radiation
- Lobular atrophy and postprostatic hyperplasia
- Transitional cell metaplasia
- Typical and atypical basal cell metaplasia
- Cribriform hyperplasia
- Cribiform, sclerotic, and intraductal urothelial carcinoma

**Treatment**

**General Measures**
- If HGPIN was found on initial prostate biopsy of <10 cores, the biopsy should be repeated with an extended scheme
- If multifocal HGPIN is found on initial prostate biopsy, the biopsy should be repeated within 1 yr
- Repeat biopsy should sample the entire prostate, not just the HGPIN area

**Medication**

**First Line**
- Not necessary to treat HGPIN
- HGPIN often used to identify patients at “high risk” of developing PCa
- May require repeat biopsy at 1 yr
- LPIN should not be diagnosed on pathology and, therefore, does not require any follow-up

**Second Line**
- No

**Surgery/Other Procedures**
- Radical prostatectomy not indicated for HGPIN in the absence of PCa

**Additional Treatment**

**Radiation Therapy**
- Not indicated for HGPIN in the absence of PCa

**Additional Therapies**
- No

**Complementary & Alternative Therapies**
- Green tea catechins for 1 yr in men with HGPIN reduced the incidence of PCa from 30 to 3%
- Soy, vitamin E, and selenium did not slow the rate of progression of HGPIN to PCa in a randomized double-blind trial (SELECT Trial)
- None of these therapies routinely recommended to men with HGPIN

**Ongoing Care**

**Prognosis**
- Excellent prognosis in the absence of PCa
- Most monitor for the development of PCa as outlined above

**Complications**
- None other than the risks of biopsy

**Follow-Up**

**Patient Monitoring**
- In certain situations as noted, HGPIN may indicate an increased risk of PCa and, therefore, may require repeat biopsy at 1 yr
- HGPIN should not be diagnosed on pathology and, therefore, does not require any follow-up

**Patient Resources**
- http://prostatecancerinfolink.net/diagnosis/pin/

- Prostatic Intraepithelial Neoplasia (PIN) Images
- PSA Elevation, General Considerations

**ICD**
- 185.4 Carcinoma in situ of prostate
- 622.3 Dysplasia of prostate

**Clinical/Surgical Pearls**
- If HGPIN was found on initial prostate biopsy of <10 cores, the biopsy should be repeated with an extended scheme
- If multifocal HGPIN is found on initial prostate biopsy, the biopsy should be repeated within 1 yr
- With modern 12-core biopsies, a single focus of HGPIN does NOT increase the risk of PCa diagnosis on subsequent biopsies
- Decision for repeat prostate biopsy should be made on other clinical factors (elevated PSA, high PSA velocity, new nodule on DRE), not influenced by the presence of 1 focus of HGPIN
PROSTATITIS, ACUTE, BACTERIAL (NIH I)
Nicholas J. Kuntz, MD
Judd W. Moul, MD, FACS

DESCRIPTION
Acute bacterial prostatitis is a rare, potentially life-threatening bacterial infection of the prostate. The symptoms are typically severe and sudden and usually cause the patient to seek emergency care. The NIH prostatitis classification system is referred to as NIH I.

EPIEDEMOLOGY
Incidence
- Usually a single bacterial uropathogen
- Hematogenous seeding
- Direct invasion or lymphogenous spread from the bladder:
  - Ascending urethral infection:
    - History of sexually transmitted disease
    - Indwelling urethral catheter
    - Immunocompromise
    - Phimosis
    - Lower urinary tract procedures
- Previous episodes of prostatitis
- Bladder outlet obstruction
- Diabetes
- Human immunodeficiency virus (HIV)
- Prostate biopsy or urethral catheterization
- Stricture disease
- Benign prostatic hyperplasia (BPH)

Prevalence
- Estimated to be ∼5% for all types of prostatitis worldwide (1B)

RISK FACTORS
- Bladder outlet obstruction
- Benign prostatic hyperplasia (BPH)
- Stricture disease
- Previous episodes of prostatitis
- Lower urinary tract procedures
- Prostate biopsy or urethral catheterization
- Phimosis
- Immunocompromise
- Immunodeficiency virus (HIV)
- History of sexually transmitted disease

ASSOCIATED CONDITIONS
- BPH
- Urinary stricture disease
- Diabetes
- HIV
- UTI

GENERAL PREVENTION
Safe sex practices may prevent some cases.

UTI
- HIV
- Diabetes
- Urethral stricture disease
- BPH

DIAGNOSIS
HISTORY
- Systemic symptoms
  - Fever, chills, malaise, arthralgia, myalgia
  - Intermittent or obstructive voiding symptoms
  - Dysuria, urgency, frequency
  - Acute urinary retention (20%)
  - Due to bladder neck spasm
  - Pelvihertral pain, lower back pain

PHYSICAL EXAM
- Avoid vigorous prostatic exam or massage in a patient with suspected acute bacterial prostatitis. This may cause bacteremia and sepsis.

PHYSICAL EXAM
- NIH classification: [IA]
  - I: Acute bacterial prostatitis
  - II: Chronic bacterial prostatitis: Recurrent infection
  - III: Chronic prostatitis/chronic pelvic pain syndrome (CPS): No demonstrable infection:
    - IIIA: Inflammatory CPS: White blood cells (WBCs) present in semen/voided prostatic secretions or voided bladder urine (VBU)
    - IIIB: Noninflammatory CPS: WBCs not present in semen/voided prostatic secretions or voided bladder urine (VBU)
  - IV: Asymptomatic inflammatory prostatitis: Detected by prostate biopsy or presence of WBCs in prostatic secretions during evaluation for other conditions

LAB
- Complete blood count
  - Leukocytosis with left shift
- Blood cultures
- Urine culture
- Stool softeners
- Analgesics/antipyretics

DIFFERENTIAL DIAGNOSIS
- UTI
- Prostatodynia
- Perirectal abscess
- Prostate cancer
- Prostatic abscess
- Prostatitis

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - Complete blood count
  - Leukocytosis with left shift
  - Blood cultures
  - Urine culture
  - Stool softeners
  - Analgesics/antipyretics
  - Prostatodynia
  - Blood cultures
  - Particularly for immunosuppressed patients
  - Prostate-specific antigen (PSA)
  - Little clinical value in the acute setting
  - US will be elevated in the majority of cases
  - Should be repeated 1–2 mo following treatment

Imaging
- Not routinely required
- Indicated if fever persists despite appropriate treatment to evaluate for prostatic abscess
  - CT scan
    - Areas of low attenuation
    - Rim enhancing with IV contrast
  - Ultrasound
  - Hypoechoic lesion
  - MRI
    - High intensity on T2-weighted images
    - Rim enhancing with gadolinium

TREATMENT
- General measures
  - Indications for admission and IV antibiotics:
    - High fever
    - Significant leukocytosis
    - Septis
  - Analgesics/antipyretics
  - Stool softeners
  - Bladder drainage if there is evidence of urinary retention:
    - An anterior catheter should be placed cautiously
    - With any difficulty or if the patient is too uncomfortable, percutaneous suprapubic tube should be placed
If no clinical response in 48 hr despite appropriate treatment consider prostatic abscess.

- Prostate biopsy: prostatitis suspect resistance to antibiotics.

**ADDITIONAL TREATMENT**

- Radiation Therapy

**ADDITIONAL READING**

**CLINICAL/SURGICAL PEARLS**

- E. coli is most common organism in acute bacterial prostatitis.
- Avoid vigorous prostatic exam or massage during an episode of acute bacterial prostatitis.
- It is not advisable to measure serum PSA during an episode of acute bacterial prostatitis as it will most likely be falsely elevated.
- Urinary retention requires bladder drainage.
- May require hospital admission and IV antibiotics.
- Consider prostatic abscess if no clinical response in 48 hr.
PROSTATITIS, CHRONIC NONBACTERIAL, INFLAMMATORY AND NONINFLAMMATORY (NIH CP/CPPS III A AND B)
Amin S. Herati, MD
Robert M. Moldwin, MD, FACS

BASICS
DESCRIPTION
- Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS), NIH categories IIA and IIIB are characterized by pelvic, perineal, and/or testicular pain ± LUTS in the absence of other well-defined pathology.
- IIA: Inflammatory CPPS: WBBCs present in prostatic secretions
- IIIB: Noninflammatory CPPS: WBBCs not present in prostatic secretions

RISK FACTORS
- Approximately 2,000,000 US men
- Estimated prevalence of CP/CPPS is 1.8%, equating to

EPIDEMIOLOGY
PREVALENCE
- N/A
- Prevalence
- Estimated prevalence of CP/CPPS is 1.8%, equating to

INCIDENCE
- N/A

INCIDENCE
- Estimated prevalence of CP/CPPS is 1.8%, equating to

DIAGNOSIS
HISTORY
- Determine duration of symptoms (of at least >3 mo durations)
- Pain in the suprapubic region, lower back, penis, testes, and/or scrotum
- Painful ejaculation: One of the most discriminatory

EXAM
- Careful exam of the genitalia, groin, perineum, and testes
- Pelvic floor muscle spasms
- Sexual dysfunction
- Pain in the suprapubic region, lower back, penis, testes, and/or scrotum
- Difficulties encountered with interpretation of

PATHOLOGY
- Nonbacterial colonization
- Atypical bacterial infection
- Invasive bacterial infection
- Voiding dysfunction causing intraprostatic urinary reflux and elevated intraprostatic pressure
- Pelvic floor muscle dysfunction
- Endocrine
- Neuropathic
- Autoimmune
- Stricture of each patient into a 6-point clinical

IMAGING
- Ural reflex or urethral abnormalities
- Bladder neck contracture
- Intravesical cysts
- Primary voiding dysfunction
- Prostate abscess
- Prostate cancer
- Prostate cyst
- Radiation cysts
- Tuberculosis of the prostate
- Urinary tract infection
- Urethritis

ASSOCIATED CONDITIONS
- Allergies
- Sinusitis
- Erectile dysfunction
- Irritable bowel syndrome
- Depression
- Fibromyalgia
- Fatigue
- Neurologic disorders

GENERAL PREVENTION
- N/A

DIFFERENTIAL DIAGNOSIS
- Acute or chronic bacterial prostatitis
- Benign prostatic hyperplasia
- Bladder calculus
- Bladder cancer
- Bladder neck contracture
- Interstitial cystitis
- Primary voiding dysfunction
- Prostate abscess
- Prostate cancer
- Prostate cyst
- Radiation cysts
- Tuberculosis of the prostate
- Urinary tract infection
- Urethritis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and urine culture
- Stamey test (Meares-Stamey 4-glass test)

DIAGNOSTIC PROCEDURES/SURGERY
- Cystoscopy
- Primary voiding dysfunction
- Prostate abscess
- Prostate cancer
- Prostate cyst
- Radiation cysts
- Tuberculosis of the prostate
- Urinary tract infection
- Urethritis

IMAGING
- Pelvic imaging with ultrasonography, CT, or MRI is

PATHOLOGIC FINDINGS
- Not formally reported for Category II, therefore N/A

DIFFERENTIAL DIAGNOSIS
- Acute or chronic bacterial prostatitis
- Benign prostatic hyperplasia
- Bladder calculus
- Bladder cancer
- Bladder neck contracture
- Interstitial cystitis
- Primary voiding dysfunction
- Prostate abscess
- Prostate cancer
- Prostate cyst
- Radiation cysts
- Tuberculosis of the prostate
- Urinary tract infection
- Urethritis
GENERAL MEASURES

Antibiotic therapy: Data conflicting on the benefit

The choice of agents in the 1st- or 2nd-line setting is

Focus of therapy should be on symptom relief

Treatment should also be targeted to the etiologic

A meta-analysis comparing – Oral prednisolone – Rofecoxib 25–50 mg daily: Symptom relief at – Dutasteride 0.5 mg daily or

α–Can be considered in antibiotic-naïve patients to 4 wk of initiating therapy – Side effects of αmade of treatment failure or success.

or longer may be needed before assessment can be

practitioner dependent with no specific agent

CP/CPPS III often requires multimodal therapy

treatment. Last resort unless other

Stamey Test (3-glass test, 4-glass tests, Meares-Stamey Test)
PROSTATITIS, CHRONIC, BACTERIAL (NIH II)
John J. Pahira, MD

PATHOPHYSIOLOGY

- Increased incidence of prostatic calculi may serve as a nidus for infection.
- Bacteria are present in inflamed ducts in protected areas of the prostate.
- Progresses to chronic intraductal inflammation.
- Obstructive, turbulent, and/or high-pressure voiding contributes to the development of prostatic calculi.
- With progressive benign prostatic enlargement, obstructive voiding becomes more pronounced.
- Unprotected intercourse, new partners, sexual activity, and ejaculation may increase the risk of prostatic calculi formation.

RISK FACTORS

- Type I: Acute bacterial prostatitis
- Type II: Chronic bacterial prostatitis, recurrent infection
- Type III: Chronic abacterial prostatitis (CAP); no demonstrable infection

EPIDEMIOLOGY

- Prostatitis affects 10–14% of men of all ages and accounts for 50 million office visits annually.
- Chronic bacterial prostatitis is the most common cause of recurrent UTI in the adult male population.

DIAGNOSIS

- **Histories:**
  - Fever and chills are not usual and suggest acute bacterial prostatitis.
  - Rectal or perineal pain, rectal, or urethral discharge may increase the risk of developing prostatic calculi.

- **Examination:**
  - Perineal, penile, scrotal, suprapubic, or groin pain; tenderness may be present.
  - Urethral catheterization or other lower genitourinary tract procedures may be performed.

Association of prostatic calculi with other diseases:

- **Prostate:**
  - Prostatic calculi may be palpable.
  - DRE may reveal a minimally tender or boggy prostate.
  - Perineal tenderness may be present.

- **PSA:**
  - PSA may be elevated in the setting of prostatic inflammation.

DIAGNOSTIC TESTS & INTERPRETATION

- **Urine analysis and culture:**
  - Positive: Routine urine culture may be negative. A positive culture may be obtained as part of the Meares-Stamey 4-glass test (see below).
  - Negative: Prostatic calculi can occur in the absence of infection.

- **Meares-Stamey 4-glass test:**
  - Void 10 mL into sterile container (VB1).
  - After voiding 100 mL, collect 10 mL midstream voided bladder urine (VB2).
  - Clean the glans thoroughly with antimicrobial solution. Retract foreskin as necessary.
  - Replace VB1 or VB2, bacterial prostatitis is present.

- **EPS:**
  - EPS result is lower than VB1 or VB2, bacterial prostatitis is present.

- **Prostatic massage:**
  - Perform prostatic massage to collect EPS from the prostate.
  - After voiding 10 mL into sterile container (VB1), collect the next voided 10 mL into another sterile container (VB2).
  - Perform bacterial culture on the urine:
    - VB1 or VB2, bacterial prostatitis is present.
  - **Diagnostic Procedures/Surgery:**
    - Prostatitis involves isolated cultures of different portions of the lower urinary tract.
    - In men, bacterial prostatitis is a treatable cause of the patient's symptoms.

- **Physical examination:**
  - **Examination of the penis:**
    - Examiners may reveal vague widespread pelvic discomfort.
  - **Prostatic infection:**
    - Perineal tenderness may be present.

- **Lab:**
  - PSA may be elevated in the setting of prostatic inflammation.

- **Meares-Stamey 4-glass test:**
  - Positive: Routine urine culture may be negative. A positive culture may be obtained as part of the Meares-Stamey 4-glass test (see below).
  - Negative: Prostatic calculi can occur in the absence of infection.

- **Imaging:**
  - Imaging has low yield and is performed only to exclude the presence of other more definable and treatable causes of the patient's symptoms.

- **Bacterial infection:**
  - Positive: The patient has a full bladder.
  - Negative: The patient has an empty bladder.

- **Diagnostic Procedures/Surgery:**
  - Prostatitis involves isolated cultures of different portions of the lower urinary tract.
  - In men, bacterial prostatitis is a treatable cause of the patient's symptoms.

- **Physical examination:**
  - **Examination of the penis:**
    - Examiners may reveal vague widespread pelvic discomfort.
  - **Prostatic infection:**
    - Perineal tenderness may be present.

- **Lab:**
  - PSA may be elevated in the setting of prostatic inflammation.

- **Imaging:**
  - Imaging has low yield and is performed only to exclude the presence of other more definable and treatable causes of the patient's symptoms.

- **Bacterial infection:**
  - Positive: The patient has a full bladder.
  - Negative: The patient has an empty bladder.

- **Diagnostic Procedures/Surgery:**
  - Prostatitis involves isolated cultures of different portions of the lower urinary tract.
  - In men, bacterial prostatitis is a treatable cause of the patient's symptoms.
PROSTATITIS, CHRONIC, BACTERIAL (NIH II)

A modified Meares–Stamey test (2-glass test) can also be performed that is considered more convenient and practical:

- After cleansing the glans, obtain 10 mL of a midstream urine for culture (prostate massage). Represents bladder flora. Should also be dipped for white cells.
- Perform prostate massage and obtain 10 mL of urine (prostate massagely may fail) for culture and microscopic exam. Represents prostate and bladder flora. If white cells are present, they may represent bacterial prostatitis or NIH type IIIA.
- If postmassage colony counts are 10× higher than postvoid sample, bacterial prostatitis is present. If both cultures have similar counts, cystitis is present.
- Semen culture is of limited use, demonstrating low sensitivity but high specificity compared to Stamey test.
- Uroflowmetry may demonstrate diminished flow with intermittency.
- Elevated PVR may be present.

Pathologic Findings

NI/A

DIFFERENTIAL DIAGNOSIS

- Acute bacterial prostatitis/systemic abscess
- Bladder outlet obstruction (BPH)
- Chronic nonbacterial prostatitis (NIH IIIA/B)
- Cystitis
- Interstitial cystitis
- Prostatitis cyst
- Serosal vesiculitis
- STDs
- Tuberculosis/granulomatous prostatitis
- Urethritis or urethral pathology (stricture)

TREATMENT

GENERAL MEASURES

- Antibiotic course normally extends for 6–8 wk and sometimes longer with refractory infections. Goal is to eradicate the risk of infection in the prostate.
- Follow culture results (3–4).
- Avoid alcohol, spicy foods, perineal pressure for extended times (sitting or bicycle riding), acidic beverages.
- Continue to engage in safe protected sexual activity, as this is thought to reduce prostatic congestion.

MEDICATION

First Line

- Current sensitivity patterns are showing increased resistance to quinolones. TMP/SMX, apricillin is choosing antibiotic coverage prior to culture sensitivity reports, know local resistance patterns based on your hospital antibiogram.
- Fluoroquinolones still preferred—no difference in bacterial eradication between levofloxacin and ciprofloxacin, although prostatic fluid concentration of levofloxacin is higher than ciprofloxacin. Levofloxacin has daily dosing and may have better prostatic penetration.
- Ciprofloxacin 500 mg PO 8–12 h or levofloxacin 500 mg for at least 6–8 wk.
- Trimethoprim 80 mg/d sulfamethoxazole 160 mg BID for at least 6–8 wk.
- Tetracycline derivatives (eg, doxycycline) only if Chlamydia or Mycoplasma suspected
- A modified Meares–Stamey test (2-glass test) can also be performed that is considered more convenient and practical:
- Follow culture results (3–4).
- Avoid alcohol, spicy foods, perineal pressure for extended times (sitting or bicycle riding), acidic beverages.
- Continue to engage in safe protected sexual activity, as this is thought to reduce prostatic congestion.

Second Line

- Anti-inflammatory (ibuprofen) for symptoms
- α-blockers (tamsulosin, alfuzosin, doxazosin) may help with LUTS

SURGERY/OTHER PROCEDURES

- Not generally recommended
- TURP
- May be considered in select cases of refractory prostatitis with infected calculi and/or obstruction

ADDITIONAL TREATMENT

Radiation Therapy

NI/A

Additional Therapies

- Frequent ejaculation (in patients with enlarged, symptomatically enlarged glands)
- Dietary modifications of common comestibles found to irritate the lower urinary tract
- Moist heat with sitz baths or heating pad for symptomatic relief

Complementary & Alternative Therapies

- Prostate massage (very controversial):
  - May work by stimulating hibernating bacterial biofilms (making them more susceptible to antimicrobials), draining the obstructed inflammatory ducts (allowing for better antimicrobial penetration), and stimulating blood supply to the area.
- Avoid bicycling or other activities that cause perineal pressure.
- Zinc supplements: Unproven benefit
- Phytotherapy: Plant extracts and herbal medications
  - Saw palmetto: popular but may only be as effective as placebo (5)

ONGOING CARE

PROGNOSIS

- Fluoroquinolones have improved the ability to clear the infection (60–90% cure reported).
- Variable course with flare-ups possible. If culture-positive infection persists, consider longer course of therapy (6–8 mo) with a lower daily dose.
- Treating underlying obstruction or prostatic calculus if necessary may prevent further infections.

COMPLICATIONS

- Recurrent cystitis, epididymitis, unexplained fever
- CPPS
- Infection effect on semen quality debatable
- Primarily affects IQOL
- Unknown if predisposes to prostate cancer

FOLLOW-UP

Patient Monitoring

- Document clearing of positive culture
- Following prostate cancer screening guidelines is recommended. Do not obtain PSA for at least 6 wk after culture clears.

CLINICAL/SURGICAL PEARLS

Inadequately treated acute bacterial prostatitis may increase risk for developing chronic prostatitis syndrome including chronic bacterial prostatitis.
PROSTATITIS, GENERAL

Ryan S. Levey, MD
Justin D. Ellett, MD, PhD

DESCRIPTION

- Prostatitis is a general term that refers to inflammation of the prostate.
- Traditionally classified as acute bacterial prostatitis, chronic bacterial prostatitis, nonbacterial prostatitis, and prostatodynia today the definitions used are much more precise and based on the NIH system (1).
- Revised 1995 NIH classification of prostatitis is standard nomenclature:
  - NIH Class I: Acute bacterial prostatitis, infection of prostate, sudden onset, often associated with UTI
  - NIH Class II: Chronic prostatitis: insidious onset, relapsing, recurrent UTI
  - NIH Class III: Chronic prostatitis: CP/CPPS

EPIDEMIOLOGY

- Most common urologic diagnosis in men
- NIH Class IIIB: Noninflammatory: Insignificant amounts of pain, prostatic calculi
- NIH Class III: Chronic prostatitis (CP)/Chronic pelvic pain syndrome (CPPS)
- NIH Class I: Acute bacterial prostatitis; infection of prostatic secretion, seminal fluid, postprostatic massage urine

PATHOPHYSIOLOGY

- Acute prostatitis: Infected prostatic tissue, prostatic abscess
- Chronic prostatitis: Infected prostatic tissue

ASSOCIATED CONDITIONS

- Conditions in lower urinary tract (dysuria, urinary frequency)
- Depression
- Chronic prostatitis
- Psychiatric conditions

DIAGNOSIS

HISTORY

- Acute bacterial prostatitis (NIH I):
  - Fever, chills, malaise
  - Perineal, suprapubic pain
  - Urgency, frequency, dysuria
- Chronic bacterial prostatitis (NIH II):
  - Recurrent UTIs
  - Asymptomatic prostate (CP/CPPS) (see below)
- Chronic bacterial prostatitis/CP/CPPS (NIH III)
- Rare sepsis
- Sepsis: Fever, chills, rigors

DIAGNOSTIC TESTS & INTERPRETATION

- PSA may be elevated with prostatic PSA should not be checked in cases of acute bacterial prostatitis
- Suspected acute bacterial prostatitis:
  - Urinalysis, urine culture, CBC, blood culture
- Suspected CP/CPPS (NIH III)
- Urinalysis, urine culture
- PSA, DRE

LAB

- PSA may be elevated with prostatic PSA should not be checked in cases of acute bacterial prostatitis
- Suspected acute bacterial prostatitis:
  - Urinalysis, urine culture, CBC, blood culture
- Suspected CP/CPPS (NIH III)
- Urinalysis, urine culture
- PSA, DRE

- Suspected acute bacterial prostatitis (NIH I):
  - Fever, chills, malaise
  - Perineal, suprapubic pain
  - Urgency, frequency, dysuria
- Chronic bacterial prostatitis (NIH II):
  - Recurrent UTIs
  - Asymptomatic prostate (CP/CPPS) (see below)
- Chronic bacterial prostatitis/CP/CPPS (NIH III):
  - Rare sepsis
  - Sepsis: Fever, chills, rigors

ALERT

Do not perform massage or aggressive rectal exam in the face of acute prostatitis or prostatic abscesses.
**Medical Information**

**Prostatitis**

### General Measures
- **Antibiotics:** For acute bacterial prostatitis (inpatient).
- NIH IV is only a histologic diagnosis and no specific therapy necessary.
- NIH II: Long-term antibiotic therapy.
- NIH IIIA/B: Similar management; empiric antibiotics when symptoms do not resolve with conventional measures; must rule out prostate abscess.
- NIH III: Acute prostatitis:
  - Afebrile 24–48 hr may change to oral antibiotics.
  - Ceftriaxone 1–2 g IV or IM daily.
  - Fluoroquinolones (e.g., levofloxacin 750 mg PO twice daily or ciprofloxacin 500 mg PO BID or tid) are effective in most cases.
- **NSAIDs/analgesics/antipyretics** useful adjuncts in this population.
- **α-adrenergic blockers:** Often used with variable success, focus on symptomatic and supportive therapy.
- **Neuromodulation (CP/CPPS):** Amitriptyline, baclofen, or tizanidine.
- **Dietary modification:** Frequent ejaculation (in patients with enlarged, symptomatic prostate) may be beneficial.
- **Stool softeners** for patients with chronic symptoms.
- **Avoid** prostate massage (not in acute prostatitis).
- **Follow-up:** Men with chronic symptoms do not benefit from further antibiotic therapy.

### Additional Therapies
- Numerous unproven therapies have been suggested with little to no evidence for treatment of CP or CPPS, including: Allopurinol, balloon dilation, TUNA, acupuncture, neuromodulation.
- Frequent ejaculation (in patients with enlarged, symptomatic prostates) is beneficial.
- Dietary modification.
- Sex therapy for symptom relief.

### Complementary & Alternative Therapies
- Prostatitis therapy provides modest benefits in CPPS.
- Neuromodulation and other modalities (e.g., TUNA, acupuncture).

### Ongoing Care
- **Follow-up:** Prostatic enlargement, prostate biopsy, and prostate cancer.
- **Complications:** Acute urinary retention, chronic prostatitis with incomplete resolution of acute bacterial prostatitis.
- **Imaging:** CT, MRI, ultrasound, transrectal US.
- **Staging:** T1, T2, T3, T4.
- **Prostate cancer:** Localized, regional, metastatic.
- **Prostatic abscess:** With conventional measures; must rule out acute prostatitis.

### Prostate Resources

### Prostatitis Code
- ICD-9: 601.0 Acute prostatitis
- ICD-10: N41.0 Acute prostatitis

### Additional Reading
- See Also (Topic, Algorithm, Media): Prostatitis, Acute; Prostatitis, Chronic; Prostatitis, Radiation Therapy; Prostatitis, Surgical; Prostatitis, Symptomatic.

### ICD-9 Code
- 601.0 Acute prostatitis
- 601.1 Chronic prostatitis
- 601.9 Prostatitis, unspecified

### ICD-10 Code
- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis
- N41.9 Prostatitis, unspecified

### Prostatitis Pearls
- Prostatitis is considered the most common urological diagnosis in men men—50%.
- If suspected CPP/CPPS, perform 2-glass test to help establish the diagnosis.
- Most chronic bacterial prostatitis cases improve after 3–4 wk of antibiotics.
PROSTATITIS, GRANULOMATOUS
Christopher Amling, MD, FACS

PATHOPHYSIOLOGY
- Specific subtypes:
  - Caused by identifiable infectious agent (mycobacterium, fungi, syphilis, brucellosis, virus, parasites)
  - It is often associated with systemic TB
  - With HIV, TB may cause prostatic abscess
- Non-specific subtypes:
  - Usually an incidental finding on biopsy
- Iatrogenic:
  - After TURP or TRUS-guided biopsy, necrotizing lesions may resemble lesions associated with neutrophilic diseases.
- Eosinophilic subtypes:
  - May occur, may suggest allergic etiology
  - Associated with systemic condition (asthma, Wegener granulomatosis, Churg–Strauss syndrome)
- Autoimmune based:
  - HLA-DR15–linked T-cell–mediated response against PSA

DIAGNOSIS
HISTORY
- Often asymptomatic
- Previous urinary tract infection (UTI) or STD
- Syphilis, TB, or other infectious etiology
- Often associated with UTI 2–3 m prior to onset of symptoms
- History of lower urinary tract symptoms (LUTS)
- Voiding symptoms including urgency, frequency, dysuria
- Obstructive voiding symptoms, including acute urinary retention
- Systemic granulomatous disease:
  - It is associated with systemic vasculitis or granulomatous disease, may have constitutional symptoms
- History of prostate or bladder cancer:
  - BCG or TURP can cause granulomatous prostatitis
  - Reves, chills, or other constitutional signs
- Suggest infectious, systemic etiology

PHYSICAL EXAM
- DRE may be normal or abnormal
- Abnormal DRE:
  - Indurated gland with/without nodule
  - Tender or non-tender
- TB prostatitis should be suspected if a draining perineal fistula is present

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis may be unremarkable
- Urine cultures:
  - Are often sterile
- Elevated erythrocyte sedimentation rate (ESR), acid phosphatase, serum eosinophils may be present
- PSA may rise transiently
- It evidence of TBMycotic disease, appropriate testing includes:
  - AFB stain of urine and semen
  - TB cultures (may take up to 10 wk)
  - Polymerase chain reaction (PCR): Genomic amplification of Mycobacterium Tuberculosis DNA
  - High sensitivity/specificity
  - Rapid: Takes 48 hr

Imaging
- TRUS
  - Limited utility except to direct biopsy
  - Appears as focal hypoechogenic area
  - Difficult to discern granulomatous prostatitis and prostate cancer
  - MRI:
    - Limited utility
    - Difficult to discern granulomatous prostate from prostate cancer on MRI

Diagnosis Procedure/Surgery
TRUS-guided prostate biopsy is needed for pathologic diagnosis.

Pathologic Findings
- Histologically granulomatous prostatitis appears as noncaseating granulomas, prominent macrophage infiltrates with occasional multinucleated giant cells (Bacillus cells) which are characteristic of granulomas
- Immunohistochemistry for osteopontin (CAM 5.2) may stain glands positive but not the macrophage infiltrate
- Macrophage infiltrate stains for macrophage marker CD68
- Fibrosis replaces parenchyma
- BCG therapy related
  - Causing or noncaseating granulomas located next to benign prostatic glands (not engulfing them)
  - Usually AFB negative
PROSTATITIS, GRANULOMATOUS

Differential Diagnosis
- Nodular DRE (necroinflammatory)
- Carcinosarcoma
- Sarcoma, small cell carcinoma, and other rare tumors and metastases
- Urethral carcinoma
- Granulomatous prostatitis
- Infectious, iatrogenic, etc. (See Risk Factors)
- Nodular DRE (benign)
- Posteric calcification and incontinence
- Erythritic duct cyst
- Scarring/erosion from prior surgery or infection
- TURP prostate biopsy
- Granulomatous prostatitis
- Rectal wall lesions (thrombosed hemorrhoid, carcinoma, etc.)

Treatment

General Measures
- Majority of granulomatous prostatitis symptoms resolve spontaneously including those that are BCG related (3–15)
- DRE changes and PSA elevation may persist
- Use antibiotics as indicated for UTI
- Symptom control
- Sit bath, fluids, anti-inflammatory or block, and other symptomatic medications
- Temporary transurethral urinary catheterization if acute urinary retention or severe symptoms are present
- TRUS biopsy is indicated for:
  - Differentiating granulomatous prostatitis from prostatic carcinoma
  - Consider rebiopsy if PSA remains elevated or DRE remains abnormal several months after treating symptomatic granulomatous prostatitis

Medication

First Line
- Antibiotics as indicated for documented UTI
- Anti-TB medications for TRB prostatitis
  - Use only for documented TB cause
  - Isoniazid, rifampin, pyrazinamide, and other ethambutol or streptomycin for initial regimen, then change based on TB isolate sensitivities
  - Pyridoxine (Vitamin B6) 25–50 mg/d to prevent isoniazid neuropathy

Second Line

Medication

Antibiotics as indicated for documented UTI
- Isoniazid, rifampin, pyrazinamide, and other ethambutol or streptomycin for initial regimen, then change based on TB isolate sensitivities
- Pyridoxine (Vitamin B6) 25–50 mg/d to prevent isoniazid neuropathy

Ongoing Care

Follow-up
- Patient Monitoring
  - Rebiopsy may be indicated if DRE remains abnormal or PSA remains elevated after treatment to avoid missing coincident prostate cancer (reported in 10–14% of cases).
  - Possible infertiltity
- Possible undetected prostate cancer

Pearls

Clinical/Surgical Pearls
- Majority of symptomatic cases of granulomatous prostatitis resolve spontaneously.
- Up to 40% of patients may develop granulomatous prostatitis after intravesical BCG
- DRE changes and PSA elevation may persist for months
- TRUS-guided prostate biopsy is needed for pathologic diagnosis.

PROTEINURIA

Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

**BASICS**

**DESCRIPTION**

- Persistent abnormal amounts or types of protein in the urine
  - May be 1st indication of renal disorders either primary (e.g., proliferative glomerulonephritis) or secondary (e.g., hypertension [HTN], lupus nephritis, diabetes [DM])
  - Marker of overall cardiovascular health

- Healthy adult excretes 80–150 mg of protein per day in urine, consisting of 30% albumin, 30% serum globulins, and 40% tissue proteins.

- Dipstick urinalysis detects proteinuria only when protein excretion > 300 mg/d:
  - Microalbuminuria: 30 and 300 mg/d
  - Most sensitive to detect early renal disease (2)

- Important to distinguish between benign (no significant proteinuria due to increased risk of associated disease) and pathologic causes of proteinuria:
  - Transient proteinuria:
    - Age
    - Associated symptoms that would suggest clinically significant proteinuria:
      - Hematuria, bone pain (myeloma)

- Presence of underlying systemic disease:
  - DM, HTN, autoimmune disorders, cardiac disease, multiple myeloma

- Quantitative test that is reliable and not dependent on concentration

- Glomerular permeability and decreased tubular reabsorption have both been proposed as possible mechanisms (2)

**ASSOCIATED CONDITIONS**

- See “Differential Diagnosis”

**DIAGNOSIS**

- Presence of underlying systemic disease:
  - DM, HTN, autoimmune disorders, cardiac disease, multiple myeloma

- Transient proteinuria triggered by:
  - Exercise, emotional stress, fever, recent illness
  - Medication-induced glomerular injury

- Associated symptoms that would suggest clinically significant proteinuria:
  - Hematuria, bone pain (myeloma)
  - Age <30 and healthy (orthostatic proteinuria) (1,2)

**RISK FACTORS**

- DM
- HTN
- Obesity (BMI > 35 kg/m²), but progression to renal disease not proven

**PATHOPHYSIOLOGY**

- **Glomerular proteinuria:**
  - Results from increased glomerular capillary permeability to albumin
  - Usually >1 g/24 hr
  - When total protein > 3 g/24 hr: Nephrotic syndrome (look for hyperlipidemia, lipoproteinuria, edema, ascites)

- **Tubular proteinuria:**
  - Inability of proximal convoluted tubule to absorb low-molecular-weight proteins such as immunoglobulin light chains, ß₂-microglobulin, amino acids, and retinol-binding protein

- **Proteinuria usually 2–3 g/24 hr**

- **Overflow proteinuria:**
  - No underlying renal disease
  - Absorptive capacity of PCT is overwhelmed by overproduction and accumulation of immunoglobulin and low-molecular-weight proteins.

- **Tissue proteinuria:**
  - Associated with a variety of diseases: myeloma, multiple myeloma.

- **Diagnosis**

- **DIAGNOSTIC TESTS & INTERPRETATION**

- **Urine dipstick:**
  - Detects all types of proteinuria
  - False positive: Alkaline urine; concentrated urine; contamination with blood; recent IV contrast dye; dilute urine; dipstick only detects albumin and will miss other plasma proteins (eg, Bence Jones proteinuria in multiple myeloma)

- **Serum creatinine to rule out renal insufficiency**

- **Blood glucose, DM**

- **Albumin to creatinine ratio or total protein-to-creatinine ratio in a random urine sample:**

- **Quantitative test that is reliable and not dependent on concentration. Less cumbersome than 24-hr collection**

- ** Split urine collection: Daytime (7 AM to 11 PM) and overnight (11 PM to 7 AM) to rule out orthostatic proteinuria**

- **Urine protein electrophoresis:** To assess for light chain immunoglobulins/Bence Jones protein associated with multiple myeloma

- **Other as indicated: Hepatitis and/or HIV testing, autoantibodies (ANA, etc.) (2)**

**PHYSICAL EXAM**

- BP measurement to rule out HTN
- Edema with nephrotic syndrome, heart failure
- Rapid pulse: Uncontrolled HTN
- Jugular venous pressure elevated, heart sounds (heart failure, HTN)
- Abdominal bruits: Renal artery stenosis

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Urine dipstick:**
  - Qualitative test only (1+ to 4+); detects protein concentration > 20–30 mg/dl
  - Cannot detect microalbuminuria; if persistently positive proceed to quantitative test (spot or 24-hr protein)

- **Urine protein electrophoresis:**
  - False positive: Alkaline urine; concentrated urine; contamination with blood; recent IV contrast dye; dilute urine; dipstick only detects albumin and will miss other plasma proteins (eg, Bence Jones proteinuria in multiple myeloma)

- **Urease for associated hematuria, casts (glomerulonephritis)**

- **Serum creatinine to rule out renal insufficiency**

- **Blood glucose, DM**

- **Albumin to creatinine ratio or total protein-to-creatinine ratio in a random urine sample:**

- **Quantitative test that is reliable and not dependent on concentration. Less cumbersome than 24-hr collection**

- **Split urine collection: Daytime (7 AM to 11 PM) and overnight (11 PM to 7 AM) to rule out orthostatic proteinuria**

- **Urine protein electrophoresis:** To assess for light chain immunoglobulins/Bence Jones protein associated with multiple myeloma

- **Other as indicated: Hepatitis and/or HIV testing, autoantibodies (ANA, etc.) (2)**
**Imaging**
- Renal US in cases of persistent proteinuria to rule out anatomic abnormality
- 3-phase CT if renal function sufficient and associated hematuria
- MRI unarguable

**Diagnostic Procedures/Surgery**
- Tissue analysis
  - Renal biopsy strongly considered for:
    - Proteinuria with hematuria
    - Proximal ARF of unknown etiology
    - Nephrotic proteinuria
    - Transplanted kidney (3)
- Cystoscopy if concurrent hematuria
- Cystoscopy with retrograde pyelogram if upper tract imaging indicated (hematuria, nephrocalcinosis) and unable to evaluate upper tracts with excretory phase imaging

**Pathologic Findings**
Depends on underlying etiology

**Differential Diagnosis**
- Glomerular proteinuria:
  - IgA nephropathy
  - Diabetic nephropathy
  - Mediation (eg, NSAIDS, captopril, lithium)
  - Minimal change
  - Primary glomerulonephritis
  - Autoimmunemia (eg, SLE, amyloidosis)
- Tubular proteinuria:
  - Obstructive uropathy
  - Trauma and drugs
  - Fanconi syndrome
- Overflow proteinuria:
  - Multiple myeloma
  - Monoclonal gammopathy of unknown significance
  - Rhabdomyolysis causing myoglobinuria
- Any hemolytic state causing hemoglobinuria
- Transplant proteinuria:
  - Revers
  - Strenuous exercise
  - Emotional stress
  - Pregnancy
  - Cold exposure
- Orthostatic proteinuria

**TREATMENT**

**GENERAL MEASURES**
- Treat specific underlying etiology.
- All patients with persistent proteinuria should be referred to a nephrologist.
- Hematology–oncology evaluation for patients with therapy-resistant proteinuria for treatment of multiple myeloma
- Mild dietary protein restriction may prevent progression of chronic kidney disease.
- Strict glycemic and BP control in diabetics
- Salt/fluid restriction for edema associated with orthostatic proteinuria

**MEDICATION**

**First Line**
- ACE inhibitors reduce proteinuria and can both prevent and slow deterioration of renal function in patients with diabetic or nondiabetic renal disease, independent of their antihypertensive effects (364): Can reduce protein excretion by 20–45%  
  - Lisinopril 2.5 mg PO, increase as tolerated
  - Ramipril 2.5–5 mg PO, 20 mg max
  - Captopril 1.25–25 mg PO BID/TID, 50 mg TID max

**Second Line**
- Angiotensin II receptor antagonists:
  - Use if side effects such as cough and angioedema develop from ACE inhibitors
  - Candesartan, eprosartan, ibesartan, losartan, valsartan
- Calcium channel blockers: May be better for HTN

**SURGERY/OTHER PROCEDURES**
N/A

**ADDITIONAL TREATMENT**

**Radiation Therapy**
N/A

**Additional Therapies**
N/A

**COMPLEMENTARY & ALTERNATIVE THERAPIES**
N/A

**ONGOING CARE**

**PROGNOSIS**
- Isolated proteinuria: degree dependent:
  - Renal transplant proteinuria: high risk of progressive kidney disease (362)
  - Nephrotic proteinuria (>3 g/d) associated with glomerular disease and high risk of progression to chronic kidney disease
  - Japanese study of screened healthy patients; cumulative incidence of ESRD over 17 yr:
    - 1.4% with 1+ proteinuria
    - 7.1% with 2+ proteinuria

**COMPLICATIONS**
- Progression to renal failure
- Proteinuria is a marker for overall cardiovascular health (362)

**FOLLOW-UP**

**Patient Monitoring**
- Transient proteinuria: Active monitoring unnecessary
- Nephrologist for any patient with large quantity of proteinuria and high-risk patients with microalbuminuria
- Monitor urine albumin-to-creatinine ratio
- Monitor serum creatinine

**REFERENCES**

**ADDITIONAL READING**

**CODES**
ICD9 100.1 Proteinuria
ICD10 1. R80.0 Isolated proteinuria
2. R80.2 Orthostatic proteinuria, unspecified
3. R80.9 Proteinuria, unspecified

**CLINICAL/SURGICAL PEARLS**
Proteinuria in excess of 500 mg/d likely represents glomerular disease.
PRUNE BELLY (EAGLE–BARRETT OR TRIAD) SYNDROME
Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

DESCRIPTION

Prune belly refers to the classic appearance of abdominal wall wrinkling and bulging flanks caused by varying degrees of abdominal wall deficiency, found almost exclusively in males (T1:1) 

- Prune belly syndrome (PBS) triad:
  - Deficient abdominal musculature
  - Bladder hypoplasia
  - Upper urinary tract anomalies (eg, dilated prostatic urethra, renal dysplasia, hydroureteronephrosis)

- Incomplete variants lack abdominal wall features; females lack genital anomalies

- Woodard classification:
  - Type I: Usually fatal, marked oligohydramnios due to severe renal dysplasia or bladder outlet obstruction with pulmonary hypoplasia and skeletal anomalies (Potter sequence)
  - Type II: Full spectrum of disease with no immediate threat to life; renal dysplasia, hypodysplastic, possible mild pulmonary hypoplasia
  - Type III: All external features of triad or incomplete variant; no evidence of pulmonary hypoplasia, mild unsalutary

- Synonyms: Eagle–Barrett or Triad syndrome

EPIDEMIOLOGY

Incidence

- 3–8/100,000 live births
- 95% males
- Higher incidence in African Americans
- Lower incidence in Hispanic population
- Increased incidence in younger mothers

Prevalence

N/A

RISK FACTORS

- Slightly increased risk in African Americans and younger mothers

Genetics

- Most cases are sporadic, with normal karyotype
- Potential inheritance patterns in rare familial cases (influenced autosomal recessive, X-linked)
- Monozygotic twins reported concordant and discordant for PBR suggests some non-genetic basis

PATHOPHYSIOLOGY

- Exact mechanism unknown:
  - Early intrauterine transient urethral obstruction
  - Mesodermal developmental defect
  - Abdominal defects due to deficient musculature medially and inferiorly
  - May be partial hypoplasia of the abdominal wall to complete absence of musculature

- Tests:
  - Usually intra-abdominal (over iliac vessels)
  - Epididymis poorly attached
  - Descent in part affected by mechanical forces (eg, large bladder, low intra-abdominal pressure)
  - Kidneys:
    - Dysplasia in 50%, to varying degrees
    - Nonobstructive hydronephrosis is common; does not correlate to degree of dysplasia
    - Urinary:
      - Dilated, tortuous, and redundant; dilated proximal
      - Increased ratio of collagen to smooth muscle
      - Poor peristalsis and ureteral coaptation lead to stasis and reflux
      - ≤75% with reflux
    - Bladder:
      - Enlarged with no significant hypotrophy
      - May have urologic pseudodiverticulum
      - Urodynamics commonly show normal compliance, delayed sensation, large capacity, 50% void with normal pressures and flow, and have low postvoid residual
  - Prostatic urethra:
    - Dilated due to prostatic hypoplasia
    - 20% can have distal obstructive lesions (eg, valves, atresia, stenosis)
  - Anterior urethra:
    - Usually normal
  - Most common anomalies:
    - Megalourethra and urethral atresia (latter can be fatal unless patent urachus)
    - Megalourethra can be caused by transient obstruction
    - Urethral defect in corpus cavernosum and spongiosum; entire phallic diates on voiding
  - Scaphoid: Defect in spongiosum; entire phallic dilates on voiding
  - Urodynamic:
    - Normal pressures and flow, and have low postvoid residual

ASSOCIATED CONDITIONS

- Genetic:
  - Turner syndrome; trisomy 13, 18, and 21
  - Beckwith–Wiedemann syndrome
  - Cardiac:
    - Atrial and ventricular septal defects, total anomaly of tricuspid valve, valvar anomalies, patent ductus arteriosus
  - Musculoskeletal:
    - Scoliosis, vertebral anomalies, congenital hip dislocation, club feet

GENERAL PREVENTION

None known

DIAGNOSIS

HISTORY

- Generalized history (eg, oligohydramnios, prenatal hydronephrosis)
- Rarely positive family history

PHYSICAL EXAM

- 75% will have nonurologic manifestations
- General: Observe for Potter facies (eg, wide-set eyes, flattened nasal bridge)
- Heart: Auscultate for murmurs due to atrial or ventricular septal defects, patent ductus arteriosus
- Lung/chest: Auscultate for pneumonia/hypertension/evaluated for pectus excavatum/carinatum
- GI: Associated with gastroschisis or omphalocele; hypoplastic anus; intestinal malrotation, atresia, or stenosis
- Urologic: Evaluate micturition, observe urinary stream, attempt to palpate testes
- Abdomen: Winkled, redundant skin over lower abdomen with bulging flanks

- Extremities: Observe for dimpling on lateral aspect of knees, knuckled knuckles, clubfoot, hip dislocation, scoliosis

GENERAL PREVENTION

DIAGNOSIS
PRUNE BELLY (EAGLE–BARRETT OR TRIAD) SYNDROME

DIAGNOSTIC TESTS & INTERPRETATION

Laboratory
- Serum electrolytes, urea nitrogen, and creatinine:
  - Nadir creatinine <0.7 mg/dL is predictive of adequate renal function through childhood.
- Urinalysis and urine culture as indicated

Imaging
- Renal US: Bladder hypertrophy, thin-walled, dilated bladders, possible oligohydramnios
- Chest x-ray (pneumothorax)
- Abdominal/pelvic MRI: to evaluate renal parenchyma
- Diagnostic ultrasound: to assess presence/degree of obstruction

Diagnosis Procedures/Surgery
- VCUG:
  - Perform while on antibiotic prophylaxis
  - Reflux in up to 75% of cases
- Reflux in up to 75% of cases
- VCUG:
  - Perform while on antibiotic prophylaxis
  - Ureteral reimplantation with or without tapering
  - DMSA at 4–6wk to assess renal parenchymal function
  - MAG3 scan to assess presence/degree of obstruction

Pathologic Findings
- Renal dysplasia on biopsy
- Ureter and bladder with increased collagen and fibrous tissue

Differential Diagnosis
- Megacystis microcolon
- Postoperative urosepsis
- Respiratory failure (early)
- Renal failure

TREATMENT

General Measures
- Primary goal is to preserve renal function and prevent UTI.
- Early aggressive surgery for dilated urinary tract without evidence of progressive renal dysfunction or UTIs should be avoided
- High complication rates
- Demonstrate proper bladder emptying
- Double voiding
- Tined voiding
- Clean intermittent catheterization (CIC)
- UTI prophylaxis
- Avoid instrumentation early to reduce UTI risk

Medication
First Line
- UTI prophylaxis: Amoxicillin 25 mg/kg/day in neonates
- Trimethoprim-sulfamethoxazole 2 mg/kg once daily or intravenous 1–2 mg/kg once daily beyond 3 mo of age

Second Line
- None

Surgery/other Procedures
- Percutaneous nephrostomy for oligohydramnios in 2nd trimester (controversial)
- Consider circumcision to reduce incidence of UTI
- Urinary tract reconstruction (eg, reimplant) is controversial due to potential for improvement or resolution, stabilization of function, and high complication rates (2)
- Early intervention may be warranted with progressive/ureteral hydroureteronephrosis, progressive renal failure, or recurrent UTIs (2)
- Temporary cutaneous orifice or bilateral cutaneous pyelostomies (avoid prolonged urethrostomies)

Follow-up

Patient Monitoring
- Serial evaluation of renal function, bladder function and emptying, and for UTIs
- Imaging is individualized

Patient Resources
- Prune belly syndrome network: www.prunebelly.org

References

Additional Reading
See Also (Topic, Algorithm, Media)
- Polyhydramnios/Oligohydramnios
- Prune Belly (Eagle–Barrett or Triad) Syndrome
- Image 4: Undescended Testes (Cryptorchidism)

Codes
- ICD9: 756.71 Prune belly syndrome
- ICD10: Q79.4 Prune belly syndrome

Clinical/Surgical Pearls
- Antireflux surgery with high complication rates; avoid if possible
- Prenatally can be difficult to distinguish from posterior urethral valves
- Goal is to avoid renal damage, UTIs

Prognosis
- Degree of renal dysplasia most important determinant of long-term survival
- Up to 1/3 develop renal failure and will require dialysis/transplantation

Complications
- Renal failure
- Respiratory failure (early)
- Recurrent UTIs
- Ureterostomy

ONGOING CARE

Follow-up
- Serial evaluation of renal function, bladder function and emptying, and for UTIs
- Imaging is individualized

Patient Resources
- Prune belly syndrome network: www.prunebelly.org

Clinical/Surgical Pearls
- Antireflux surgery with high complication rates; avoid if possible
- Prenatally can be difficult to distinguish from posterior urethral valves
- Goal is to avoid renal damage, UTIs
PSA ELEVATION FOLLOWING NEGATIVE PROSTATE BIOPSY

Michael J. Amirian, MD
Leonard G. Gomella, MD, FACS

RISK FACTORS

Prevalence

- In the United States annually, 800,000–1.2 million prostate biopsies are performed.

Incidence

- EPIDEMIOLOGY

- PSA ELEVATION FOLLOWING NEGATIVE PROSTATE BIOPSY

PATHOPHYSIOLOGY

- 12-biopsy cores from a standard 18G needle enables only 0.04% of prostate gland to be evaluated for pathology.
- PSA elevations can be from non-PCa causes.
- Series reporting follow-up biopsy results (1):
  - In 2012 Ca detection rates on follow-up biopsies 1, 2, 3, and 4 were 2%, 10%, 5%, and 4%, respectively, 58%, 60.9%, 86.3%, and 100% of patients who had RP had organ-confined disease on biopsies 1, 2, 3, and 4.
- A 2008 series with extended biopsies found CaP 18%, 7%, and 14% of patients had CaP in 2nd, 3rd, and 4th biopsies, respectively, significant CaP in 85% of cases (3).

ASSOCIATED CONDITIONS

The following can cause elevated PSA; infection, recent instrumentation, benign prostatic hypertrophy (BPH)

GENERAL PREVENTION

- Obtain serial PSA at same lab, avoid sexual activity for 24 hr before
- Preventing a false-negative PB is greatly dependent on technique
  - 12-core template is now standard
  - 6 parasagittal plus 6 lateral cores
  - Szent (6-core) biopsy can miss up to 50% of small tumors
  - No evidence of increased complication rate of 12-core compared to sextant biopsy

DIAGNOSIS

HISTORY

- Prior history of negative prostate biopsies
- Evaluate for nonmalignant causes of elevated PSA
  - Prostatitis
  - Recent instrumentation of prostatic ducts
  - Rarely sexual activity, bicycling can briefly elevate
  - Recent instrumentation of genitourinary tract
  - Endo-anal ultrasound
  - BPH more likely with elevated PSA and negative biopsy
  - Consider exogenous androgen exposure

DIAGNOSTIC TESTS & INTERPRETATION

- Lab
  - Prostate-specific antigen (PSA) (4)
  - Prostate-specific antigen < 3 (PCa)
  - 1st voided urine after attentive digital rectal exam
  - PSA approved for men >50 yr who have had or more previous negative biopsies
  - Cutoff debatable 25–35
  - Compared to PSA
    - Lower sensitivity (67%); Higher specificity (83%)
    - Some studies suggest superior to F/T PSA
    - Patient stratified into lower risk or higher risk of having a positive biopsy

- Imaging
  - MRI may identify anterior tumor not reached by biopsy needle
  - 12-weighted MRI
  - Observe local lesions within gland
  - Need to wait 6–8 wk after negative biopsy as recent biopsies cause distortion
  - Multiparametric (mp) MRI
  - Combination of dynamic contrast-enhanced MRI, MR spectroscopic imaging, and diffusion-weighted imaging; need access to experienced center
  - Contrast enhanced TRUS
  - Neovascularity of tumor enhances with microbubble contrast agent (not FDA approved)
  - Targeted biopsy show increase sensitivity from 38–65% vs. untargeted imaging
  - Color Doppler of limited utility w/o contrast
  - Elastography ultrasound: Tumors allow less displacement with compression than normal tissue; color coded map allows targeted biopsy; not widely available
  - MRI TRUS fusion biopsy may help identify specific lesions for directed biopsy

Diagnostic Procedure/Surgery

- Mapping/saturation biopsy
  - Dilation of 20 or more cores with standard biopsy technique; can be transrectal but more likely to be done transperineally using a brachytherapy-like template guide
  - Studies vary in yield of detection with increased cores; increased morbidity
  - Usually require additional anesthesia
  - Transthoracic zone targeted biopsy
  - 15% increased detection in gland >50 cc
SURGERY OTHER PROCEDURES
• The number of cores on repeat biopsy is debatable. NCCN guidelines suggest performing a 2nd extended biopsy and consider saturation biopsies only in with high risk of cancer after multiple negative biopsies
• Transrectal needle prostate biopsy
• Once advocated for diagnosis of transition zone cancers
• Less than 5% CaP are transitional zone CaP without concomitant peripheral zone tumors
• Improved TRUS technique in sampling transitional zone, no definite value in performing transperineal repeat biopsy

ADDITIONAL TREATMENT
Radiation Therapy

Additional Therapies
• The European Randomized Study of Screening for CaP (ERSPC) model has several calculators to determine outcome after negative biopsy (http://www.prostatecancer-riskcalculator.com/)
• Genomic testing may help determine risk after negative biopsy
• Confirm MDxTM Epigenetic assay to distinguish negative biopsy
• Confirms microscopically occult cancer

Ongoing Care

See Also (Topic, Algorithm, Media)
• PSA (Prostate Specific Antigen, percentage free)
• Prostate Cancer, General
• Prostate Biopsy, Infections and Complications
• PSA, General Considerations
• PSA, Free and Total
• PSA, General Considerations

CODes
ICD9
• 790.93 Elevated prostate specific antigen (PSA)
• 185 Malignant neoplasm of prostate
• 186 Malignant neoplasm of prostate

ICD10
• C61 Malignant neoplasm of prostate
• 185.9 Prostate cancer, unspecified
• 186.9 Prostate cancer, unspecified

Clinical/Surgical Pearls
• Threshold for repeat biopsy should be low if any疑 on initial biopsy.
• PCA3 can elucidate the need for further biopsy in those with prior negative biopsy and persistently elevated PSA.
• Emerging imaging modalities are promising in detecting CaP not found on initial MR.
EPIDEMIOLOGY

- PSA is used for diagnosis and treatment of prostate cancer (CaP).
- CaP is only diagnosed through tissue biopsy and not by PSA alone.
- Normal PSA level is controversial, and can be elevated due to malignant or benign causes:
  - Elevated PSA traditionally ≥ 4.0 ng/mL, based on the Baltimore Longitudinal Study of Aging.
  - Specificity 91%, sensitivity 21% (51% for Gleason ≥ 3, P< 0.0001).
- Elevated PSA ≥ 2.5 ng/mL has support based on genetic specific risk, but controversial.

<td>0–5.5</td>
<td>0–6.5</td>
</tr>
</tbody>
</table>

- Based on Prostate Cancer Trial Trial (prior): regardless of PSA, can have CaP with "low" PSA. No lower cutoff or normal PSA to indicate absence of cancer: ICFP data.

- PSA is used for diagnosis and treatment of prostate cancer.
- CaP associated with kallikrein genes (family): long arm of chromosome 19 region q13.2–q13.4. (HNLX1).

PATHOPHYSIOLOGY

- PSA: A serine protease produced by the prostatic epithelium and perineural glands that liquefies seminal coagulum.
- Seminal fluid has high PSA concentrations (mg/mL).
- Several forms of serum PSA: Free PSAs (nicked, intact), proPSA (prostate forms: stable complex (no serum enzymatic activity)) (2).
- 60–90% complexed to ALP, free portion is also detected by assay, while that bound to MS is not detected by assay.
- Consider %FPSA (FPSA/TPSA or F/T PSA).

DIAGNOSTIC TESTS & INTERPRETATION

- PSA elevation likely (See "Risk Factors" above).
- Consider PSAD: PSA density (PSAD), PSA velocity (PSAV), newer PSA derivatives may overcome problem, but not yet clear.
- Complexed PSA: Hepatic clearance (1/2-life 2–3 hr).
- FPSA cleared by glomerular filtration (1/2-life 3.5 days).
- Complexed PSA: Hepatic clearance (1/2-life 2–3 days).
- FPSA clearance.
- Consider evaluation for prostatitis by modified DRE.

DIAGNOSIS

- Difficulty with urination, such as hesitancy, straining, weak stream, or intermittency.
- Dysuria, frequency, or urgency.
- Previous PSA levels or prostate biopsies.
- Family history of prostate carcinoma.
- Medications, including herbs.
- Markedly elevated PSA > 20 ng/mL with bone, back, or hip pain suggests metastatic CaP.

PHYSICAL EXAM

- DRE: Nodules, induration, asymmetry, boginess, tenderness. Note: American Cancer Society recommends PSA screening with or without DRE.
- Adenopathy, suprapubic.
- Bony pain, point tenderness with metastasis.
- Neurologic: lower extremity strength/sensation.

PSA ELEVATION, GENERAL CONSIDERATIONS

Leonard G. Gomella, MD, FACS
Adam P. Dicker, MD, PhD
GENERAL MEASURES

DIFFERENTIAL DIAGNOSIS

See Section I: “Prostate Cancer, General.”

Pathologic Findings

Imaging

Some published prostate biopsy indications:

AUA 2013 CaP Early Detection Guideline (4):
- Due to PSA fluctuations, confirm an elevated PSA with a 2nd reading before biopsy. Patient should not ejaculate for 48 hr before test.
- With bacterial prostatitis, treat and repeat PSA 4 wk after: Fluoroquinolone (eg, ciprofloxacin 500 mg BID) or TMP-SMX (180/800 mg BID)

Second Line

SURGERY/OTHER PROCEDURES

If patient has undergone prostatectomy, consider transperineal prostate biopsy for CaP diagnosis

ADDITIONAL TREATMENT

- CaP risk calculators are available on the internet to predict outcome of biopsy:
  - PCA3 urine testing after attentive DRE; FDA approved only after initial negative biopsy
  - PCA3/TMPRSS2-ERG urine test (investigational)

Additional Therapies

- Any PSA rise while on finasteride/dutasteride baseline is now standard for CaP.

PSA ELEVATION, GENERAL CONSIDERATIONS

- Failure to diagnose cancer; patient anxiety over repeat testing; risk of biopsy and drugs.

FOLLOW-UP

- Patient Monitoring:
  - There is no single threshold PSA which should prompt prostate biopsy. Decision making based on PSA, DRE and multiple factors (FT/PSA, age, PSA density, family history, ethnicity, prior biopsy history, comorbidities, patient preferences)
  - F/T PSA: Consider biopsy or obtain FPSA

CLINICAL/SURGICAL PEARLS

- Some published prostate biopsy indications:
  - Prostate nodule, regardless of PSA
  - PSA > 10 ng/mL in the absence of prostatitis
  - PSA > 4.0 ng/mL and PSAV < 0.25 ng/mL/yr
  - PSA > 4.0 ng/mL and PSAV < 0.03–0.05 ng/mL/yr
  - PSA > 2.5 ng/mL and PSAV < 0.4 ng/mL/yr
  - PSA < 1.5 ng/mL and PSAV < 0.1 ng/mL/yr

- Numerous assays under study to help differentiate benign from malignant PT elevation (See Section II: “PSA, General Considerations.”)

- N90.0 Enlarged prostate without lower urinary tract symptoms

- C61.2 Elevated prostate specific antigen (PSA)
PSEUDOHERMAPHRODITISM, MALE (XY DSD) AND FEMALE (XX DSD)

Luigi Avolio, MD

DESCRIPTION
- Pseudohermaphroditism is an obsolete term that referred to pathologic conditions in which chromosomal sex is inconsistent with phenotypical sex.
- Disorders of sexual development (DSD) is the preferred term which indicates a congenital condition in which development of chromosomal, gonadal or anatomic sex is unusual.
- Female pseudohermaphroditism is now defined as XX DSD.
  - Karyotype 46 XX
  - Gonads: Normal ovaries
  - External genitalia: Incomplete virilization
  - Karyotype 46 XY
  - Gonads: Normal testes
  - External genitalia: Incomplete virilization

EPIDEMIOLOGY
- Incidence
  - 1 in 5,000 live births
- Disorders of androgen synthesis
  - Maternal androgen excess:
    - P450 oxidoreductase (POR) deficiency: Combined 11β-hydroxylase deficiency (11-OHD, CAH) and aromatase deficiency
  - β-Hydroxysteroid dehydrogenase (HSD17B3) deficiency
  - perinatal males with ambiguous genitalia and normal gonadal sex
  - Edwards syndrome (5 or more de novo translocations of chromosome 18)
  - Philadelphia translocation (abnormality of chromosome 22)
  - Fetal exposure to maternal androgens: Absence of maternal estrogen or high levels of maternal androgens

BASICS
- Newborns with salt-wasting 21-OHD CAH are at risk for life-threatening salt-wasting crisis.
- β-Hydroxysteroid dehydrogenase (HSD17B3) deficiency: Deficiency of this enzyme results in adrenal insufficiency due to lack of conversion of 11-deoxycorticosterone (DOC) to 11-deoxycortisol (DC). This is the 2nd most common cause of congenital adrenal hyperplasia (CAH). 1:1,150,000 live births

ASSOCIATED CONDITIONS
- Hypopituitarism
- Cryptorchidism
- Inguinal hernia

GENERAL PREVENTION
See "Disorders of Sex Development" chapter
**DIFFERENTIAL DIAGNOSIS**

- Congenital Adrenal Hyperplasia
- Feminizing genitoplasty (during the 1st 6 mo of life) (3)

**ADDITIONAL READING**

**ADDITIONAL TREATMENT**

- Fertility: LHRH agonist for male adolescents
- Hormone replacement therapy: Glucocorticoid and mineralocorticoid replacement
- Avoidance of exposure to glucocorticoids during pregnancy

**REFERENCES**

**ADDITIONAL READING**

**CODES**

- ICD9: 752.7 Indeterminate sex and pseudohermaphroditism
- ICD10: Q56.3 Pseudohermaphroditism, unspecified

**CLINICAL/SURGICAL PEARLS**

- Infants with a DSD presenting with truly ambiguous genitalia are a rare occurrence.
- DSD should be regarded as a heterogeneous group of conditions with substantially different prognoses and treatment prospects.
- DSDs represent a broad complex field that requires the interaction of multiple disciplines with a diverse knowledge base.
BASICS

DESCRIPTION

- An inflammatory process that involves the renal pelvis and parenchyma.
- Most often ascending infection from the lower urinary tract.
- It is most often a result of bacterial infection, but fungi, parasites, and viruses may be involved.
- Classified as uncomplicated or complicated (ie, associated with obstruction, anatomic anomaly, or stones) making treatment more difficult.

EPIDEMIOLOGY

Incidence

- Estimated at 15–17 cases per 10,000 females and 3–4 cases per 10,000 males.
- Highest among young women, then infants, then the elderly.

RISK FACTORS

- Anatomic or functional abnormalities: Incomplete emptying of the bladder—vulvar is more prone to infection.
- Peptic ulcers, reflux nephropathy, neurogenic bladder, BDD
- Foreign body: Acts as a nidus for bacterial colonization and infection.
- Calculous disease: Mediastinal sponge kidney
- Indwelling catheters
- Medical conditions: Diabetes mellitus, immunosuppression, alcohol abuse
- Social: Poor perineal hygiene (soiling)

Genetics

Related to vesicoureteral reflux

PATHOPHYSIOLOGY

Women are at increased risk because the female urethra is shorter and in close proximity to the anus, allowing enteric organisms to more easily colonize the urinary tract.

- Most common organism are gram-negative rods: Acinetobacter, Aeromonas, Pseudomonas, Proteus, or Enterobacter sakazakii
- Other organisms: Bacteroides fragilis, Clostridium perfringens, enterococcus, and Clostridium difficile
- Enterococcus faecalis is the 2nd most common organism (5–10%)

Bacteria enter urinary tract:
- Ascending infection: Urithra and bladder
- Results from colonization of the vaginal intritus with local flora in females.
- Lymphatic and hemogenous dissemination to the kidneys is uncommon.
- Bacteria adhere to the urothelium, with subsequent invasion and inflammatory response
- Adhesins and fimbrins: Allow bacteria to adhere to urothelium
- Lipo polysaccharides: Have toxic and inflammatory effects
- Hemolysins: Allow for bacterial invasion by damaging cells
- Aerobacter: Enables bacteria to compete for iron, necessary for aerobic metabolism and reproduction

ASSOCIATED CONDITIONS

See “Risk Factors”

GENERAL PREVENTION

- Eliminate anatomic/functional abnormalities
- Patients with recurrent infections may require low-dose prophylactic antibiotics
- Proper indwelling catheter management

DIAGNOSIS

HISTORY

- Fever, chills, malaise, nausea, vomiting (2)
- Pain or abdominal pain
- Dysuria, urgency or frequency, gross hematuria
- Prior episodes of UTI
- History of renal calculus or urinary tract abnormalities
- History of vaginal discharge and irritation makes a urinary source less likely
- History of diabetes, immunosuppression, or alcoholism; recent instrumentation
- Children may present with failure to thrive

PHYSICAL EXAM

- Vital signs for signs of sepsis
- CVA tenderness
- Vital signs for signs of sepsis
- WBC casts indicate renal source of infection

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukocytosis with neutrophil predominance (80%)
- Serum chemistry: Renal failure uncommon unless obstruction is present (2)
- Blood culture: 12% of hospitalized pyelonephritis patients may have bacteremia
- Pregnancy test in women
- Urinalysis: Pyuria = 5–10 WBC/mm³
- WBC cast indicates renal source of infection
- Hematuria and bacteria may be present
- Leukocyte esterase often positive, but nitrite may not be positive with staph or enterococci
- Gram stain urine may rapidly identify organism

Pathologic Findings

- Urine culture: Positive with > 100,000 bacteria/mL and identifies causative organism; 10,000 bacteria/mL suggests acute pyelonephritis in patients with catheterized urine samples
- Newer data suggests that urine cultures may be negative especially if patients were started on antibiotics prior to presentation

Imaging

- In uncomplicated acute pyelonephritis, imaging studies are unnecessary; however, the combination of fever and flank pain especially with elevated WBC count requires imaging to rule out urolithiasis, a compromised urinary tract, which, with fever and infection, is a surgical emergency (2)
- Failure to respond to appropriate therapy within 72 hr requires radiographic evaluation to rule out obstruction, abscess, or other abnormalities
- Pediatric patients are at risk of sepsis and should undergo imaging

- Abdominal e-ray (KUB): Evaluate for renal or ureteral calculus
- Intravenous pyelogram: Empyema of pyelonephritis
- Renal shadow may be enlarged and poorly defined secondary to parenchymal edema
- IVP: 75% of patients with uncomplicated acute pyelonephritis will have a normal IVP
- EUS: Mostly used to rule out other abdominal pathology

- CT: Noncontrast CT of the abdomen reveals an enlarged kidney (> 5 cm in length or 1.5 cm greater than the unaffected side with decreased nephrogram and delayed excretion)
- Contrast administration may be seen
- Focal enlargement of the kidney is consistent with focal bacterial nephritis, or acute focal nephronia may be confused with tumor or abscess
- Noninvasive assessment of the renal pelvis and ureter may be present (endoscopy: inferimal ureteral stent)

- US: Renal enlargement with hyperechoic parenchyma and loss of corticomedullary differentiation
- Noninvasive; no ionizing radiation
- CT: Noncontrast CT of the abdomen reveals an enlarged kidney with decreased attenuation of parenchyma, and perinephric fat stranding
- Contrast administration shows delayed excretion with delayed excretion
- Radiocalcium scan: Cortical agents (eg, DMSA) reveal decreased activity in the affected kidney
- Useful to identify areas of scarring

Diagnostic Procedures/Surgery

- Delayed renal function evaluation
- Urinary tract infection identified
- Renal stone removal

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukocytosis with neutrophil predominance (80%)
- Serum chemistry: Renal failure uncommon unless obstruction is present (2)
- Blood culture: 12% of hospitalized pyelonephritis patients may have bacteremia
- Pregnancy test in women
- Urinalysis: Pyuria = 5–10 WBC/mm³
- WBC cast indicates renal source of infection
- Hematuria and bacteria may be present
- Leukocyte esterase often positive, but nitrite may not be positive with staph or enterococci
- Gram stain urine may rapidly identify organism
- Urine culture: Positive with > 100,000 bacteria/mL and identifies causative organism; 10,000 bacteria/mL suggests acute pyelonephritis in patients with catheterized urine samples
- Newer data suggests that urine cultures may be negative especially if patients were started on antibiotics prior to presentation

Pathologic Findings

- Gross: Erythematous kidney with multiple foci of infarction
- Microscopic: Focal areas of destruction of renal architecture with lymphocytic infiltrates

DIFFERENTIAL DIAGNOSIS

- Any intra-abdominal inflammatory process
- Appendicitis, cholecystitis, diverticulitis, pancreatitis, peptic ulcer disease
- Gynecologic conditions: Pelvic inflammatory disease, atrophic pregnancy, ruptured ovarian cysts
- Urologic conditions: Renal colic with fever
- Renal and perinephric abscesses
- Lower lobe pneumonia
- Musculoskeletal pain
**TREATMENT**

**GENERAL MEASURES**
- Supportive care consists of hydration, antipyretics, and analgesics.
- Empirical antibiotics that are active against the possible causative organisms and achieve adequate levels in the renal parenchyma and urine are used.

**MEDICATION**

**GENERAL MEASURES**
- Assess for underlying causes before therapy is started.
- Inpatient therapy: If signs of sepsis, bacteremia, or high probability of complications, hospitalization is preferred.
- Outpatient therapy: In uncomplicated acute pyelonephritis, outpatient therapy can be considered.
- Empiric antibiotics that are active against the possible causative organisms and achieve adequate levels in the renal parenchyma and urine are used.

**SURGERY/OTHER PROCEDURES**
- Diversion with indwelling stent or percutaneous nephrostomy may be needed in patients with urinary tract obstruction.
- Neonatal candidemia should be treated with a longer course of antifungal agents.
- Radiographs and renal ultrasonography may be needed to detect calculi or urinary tract obstruction.
- Pregnancy considerations: Pregnant patients have recurrent episodes of pyelonephritis may benefit from prophylactic antibiotics.

**ONGOING CARE**
- With 1st episode of acute pyelonephritis, 1-yr risk of a 2nd episode was 9.2% in females and 5.7% in males.
- With a 4th episode, the risk of a 5th infection was 50% for females and males.

**COMPLICATIONS**
- Short term:
  - Septic shock
  - Abscess formation (corticomedullary, perinephric)
  - Papillary necrosis
  - Long term: Renal failure

**AORTIC INFECTIONS**
- Patients with calculi or urinary tract obstruction who have recurrent episodes of pyelonephritis may develop xanthogranulomatous pyelonephritis: Characterized by large nonfunctioning renal mass and stones present in 80% of cases.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

ICD9 590.10 Acute pyelonephritis without lesion of renal medullary necrosis
593.73 Other urologic reflex with reflex nephropathy NOS

ICD10 B96.20 Unsp Escherichia coli as the cause of disease elsewhere
N13.729 Vesicoureter-reflux w reflux nephropathy non-inferiority trial

**CLINICAL/SURGICAL PEARLS**
- Some patients may be unresponsive to therapy if started on recent antibiotics.
- If fever lasts for more than 72 hr after antibiotics, obtain an CT scan to rule out obstruction, soft tissue infection, or abscess formation.
PYELONEPHRITIS, ACUTE, PEDIATRIC
Ross M. Decker, MD, FRCS
Paul H. Smith III, MD

ASSOCIATED CONDITIONS
- Tubular nephritis: Pyelonephritis affecting only an isolated focus within the kidney
- Pyonephrosis: Purulent material within the collecting system
- Renal abscess

GENERAL PREVENTION
- Prophylactic antibiotics in patients with recurrent episodes of UTI or with VUR
- Surgical correction of anatomic urinary tract anomalies

DIAGNOSIS

DESCRIPTION
- Inflammatory response initiated by interaction between bacterial endotoxin and toll-like receptor (TLR) 4 (1)

DIAGNOSTIC TESTS & INTERPRETATION
- Elevated CRP, ESR, procalcitonin
- Blood cultures: Leukocytosis with left shift
- Urine culture: Specimen collected by clean catch, catheterization or suprapubic aspiration (SPA)

GENERAL SUPPORTIVE MEASURES
- Volume resuscitation, antipyretics, analgesics

GENERATING REALITY
- E. coli – P fimbriae
- Other common organisms are Klebsiella, Enterobacter, Enterococcus, Pseudomonas, Staphylococcus saprophyticus, Enterobacter

HISTORY
- Non-specific symptoms or failure to thrive in young children
- Fever, nausea, vomiting
- Flank or abdominal pain
- Hematuria, dysuria, foul smelling urine, frequency, urgency
- History of UTIs
- Functional or anatomic urinary tract anomalies

PHYSICAL EXAM
- Fever
- Sepsis
- CVS tenderness
- Exam findings non-specific in young children

DIFFERENTIAL DIAGNOSIS
- Other intra-abdominal process
- Pyonephrosis
- Renal abscess

IMAGING
- Renal and bladder ultrasonography (RBUS)
- Failure to improve clinically within 1st 2 days of antibiotic treatment should prompt evaluation with RBUS to evaluate for complications
- Renal abscess
- Pyonephrosis

LAB
- Urinalysis
- Urine culture
- WBCs: >5 per HPF
- Presence of any bacteria
- Positive leukocyte esterase
- Positive nitrites: ∼50,000 CFU signifies positive culture
- FBC: leukocytosis with left shift
- Blood cultures
- Elevated CRP, ESR, procalcitonin

FIRST LINE MEDICATION
- Empiric coverage
- Tailor to local antimicrobial resistance patterns

TREATMENT
- First Line
- Ampicillin (25–50 mg/kg/d) + gentamicin (2–3.5 mg/kg TID)
- 3rd generation cephalosporin in alternative to ampicillin if low risk for enterococcal UTI
PYELONEPHRITIS, ACUTE, PEDIATRIC

**FOLLOW-UP**

- **Patient Monitoring**
  - Current American Academy of Pediatrics guidelines recommend RUS in children with febrile UTI.
  - Selective VCGUS in patients with abnormal RUS or recurrent episodes (2).
  - Indications for radiographic imaging in children with 1st episode of febrile UTI remain controversial.
  - Delayed DMSA scan to detect renal scarring.

- **Patient Resources**

**REFERENCES**

**ADDITIONAL READING**

**ADDITIONAL TREATMENT**

- **Radiation Therapy**
  - N/A
- **Complementary & Alternative Therapies**
  - Probiotics (experimental)

**ONGOING CARE**

- **PROGNOSIS**
  - Related to degree of renal injury from pyelonephritic scarring.

- **COMPLICATIONS**
  - Pyelonephritic scarring, especially with recurrent episodes and delayed treatment.
  - Pyonephrosis.
  - Renal abscess.
  - Xanthogranulomatous pyelonephritis.
  - Hypertension.

**CODING**

- **ICD9**
  - 041.49 Other and unspecified Escherichia coli [E. coli]
  - 590.10 Acute pyelonephritis without lesion of renal medullary necrosis
  - 593.73 Other vesicoureteral reflux with reflux nephropathy I65

- **ICD10**
  - B96.20 Unsp Escherichia coli as the cause of diseases classified elsewhere
  - N10 Acute tubulo-interstitial nephritis
  - N13.729 Vesicoureter-reflux w reflux nephropathy w/o hydrour, unsp

**CLINICAL/SURGICAL PEARLS**

- Signs and symptoms are often nonspecific in infants and young children with pyelonephritis.
- Culture of appropriately collected urine specimen mandatory in patients with suspected UTI and in infants with fever and no obvious source.
- Acute imaging (RUS) recommended if critically ill or failure to respond to treatment.

See Also (Topic, Algorithm, Media)

- **Pyelonephritis, Acute, Pediatric Image**
- Pyonephrosis
- Urinary Tract Infection (UTI), Complicated, Pediatric
- Urinary Tract Infection (UTI), Pediatric
- Vesicoureteral Reflux, Pediatric

**SECOND LINE**

- Vancomycin if penicillin allergic.
- Aztreonam an alternate to aminoglycoside if renal insufficiency.

**SURGERY/OTHER PROCEDURES**

- Urethral catheter if critically ill or poor bladder emptying.
- Surgery generally not indicated in acute treatment.
- Ureteral stent or nephrostomy tube if obstruction.
- Percutaneous aspiration/drainage if progression to renal abscess.

**ONGOING CARE**

- **PROGNOSIS**
  - Related to degree of renal injury from pyelonephritic scarring.

- **COMPLICATIONS**
  - Pyelonephritic scarring, especially with recurrent episodes and delayed treatment.
  - Pyonephrosis.
  - Renal abscess.
  - Xanthogranulomatous pyelonephritis.
  - Hypertension.
ASSOCIATED CONDITIONS
- VUR
- Spinal cord injury
- Xanthogranulomatous pyelonephritis (XGP) is a form of chronic pyelonephritis.
  – Presents with foamy lipid laden macrophages
  – Often unilateral and associated with longstanding obstructing nephrolithiasis

GENERAL PREVENTION
- Upper urinary tract evaluation in patients with recurrent bacteriuria or recurrent acute pyelonephritis
- Early detection, evaluation, and treatment of childhood VUR
- Prompt detection and management of VUR
- Detection and treatment of obstructive uropathy

Diagnostic Tests & Interpretation
- CT reveals the typical findings of chronic pyelonephritis.
  – Small or atrophic kidney, unilaterally or bilaterally
  – Compensatory hypertrophy with unilaterial atrophy
  – Blurred and dilated calyces
  – Renal cortical scarring and thinning of the cortex
- Renal US to evaluate for hydronephrosis, renal anatomy, or stones. Not a good test to identify active reflux, but dilated ureters suggest obstruction or reflux.
- VCUG for the evaluation of reflux
- CT is more sensitive than US for nephrolithiasis; also to rule out obstruction, hydronephrosis, stone disease, urinary tract abnormality. Pyelonephritis or abscesses are usually identified if present.
- Technetium-99m DMSA is the best study to evaluate for renal scarring

Diagnosis Procedure/Surgery
- VUR or anatomical abnormality
- Reflux nephropathy
- Renal biopsy

Pathologic Findings
- Gross kidney is often diffusely contracted, scarred at periphery with thin cortex
- Microscopically, an interstitial infiltrate of lymphocytes, plasma cells, and occasional neutrophils is present
- Scarring is often polar with underlying calyceal blunting. Histologic changes are patchy.
- Periglomerular fibrosis is often seen
- Leukocytes and hyaline casts can be present in tubules, and the hyaline casts may resemble thyroid collagen, hence the description renal thyroidization

PHYSICAL EXAM
- HTN may be present
- Nonspecific, unless associated with an episode of acute pyelonephritis
- May be mild flank pain or CVA tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis may be normal or indicate proteinuria or pyuria. WBC casts can be seen.
- Urine culture is usually only positive with an active, symptomatic infection. Culture is often negative.
- Microalbuminuria/proteinuria is an adverse prognostic sign.

Imaging
- CT reveals the typical findings of chronic pyelonephritis.
  – Small or atrophic kidney, unilaterally or bilaterally
  – Compensatory hypertrophy with unilaterial atrophy
  – Blurred and dilated calyces
  – Renal cortical scarring and thinning of the cortex
  – Renal US to evaluate for hydronephrosis, renal anatomy, or stones. Not a good test to identify active reflux, but dilated ureters suggest obstruction or reflux.
  – VCUG for the evaluation of reflux
  – CT is more sensitive than US for nephrolithiasis; also to rule out obstruction, hydronephrosis, stone disease, urinary tract abnormality. Pyelonephritis or abscesses are usually identified if present.
  – Technetium-99m DMSA is the best study to evaluate for renal scarring
Differential Diagnosis
- Acute nephritis
- Diabetic nephropathy
- Glomerulonephritis
- Infections
- Nephrotic syndrome
- Renal artery disease
- Renal transplantation
- Renal tuberculosis
- Urolithiasis
- Xanthogranulomatous pyelonephritis (XGP) [2]

Treatment

General Measures
- Chronic pyelonephritis is difficult to manage as it is an irreversible process
- With mild VUR, suppressive antibiotics are used until resolution or puberty in children
- Severe reflux may require reimplantation
- Correct anatomic anomalies or stones if possible

Medication

First Line
- Acute episodes of pyelonephritis should be treated (See Section 1: “Pyelonephritis, Acute”) [3]
- Suppressive antibiotics VUR in children has become controversial:
  - In children <3-6 mo, use low-dose amoxicillin or cephalaxin, cefazolin, or other 1st-generation cephalosporin can be considered
  - In children >6 mo, switch to trimethoprim-sulfamethoxazole, or trimethoprim alone can be considered
- Hyperension is best treated by ACE inhibitors (lisinopril, enalapril, ramipril) that may also protect the kidney from progressive renal failure
  - ACE inhibitors are contraindicated in pregnancy

Second Line
- Based upon urine culture sensitivities, prior treatment attempts and patient presenting symptoms

Surgery/Other Procedures
- Correction of reflux may be necessary in children with high-grade reflux (Grade 4-5). Low-grade reflux (Grade 1-3) often resolves with time
- Nephrectomy for persistent/recurrent infection unresponsive to systemic treatment, markedly decreased function (ie, 10%), pain, or refractory HTN

Additional Treatment
- Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

Additional reading
- See Also (Topic, Algorithm, Media)
  - Pyelonephritis, Acute
  - Pyelonephritis, Chronic
  - Pyelonephritis, Xanthogranulomatous
  - Vesicoureteral Reflux, Pediatric

Codes

ICD9
590.00 Chronic pyelonephritis without lesion of renal medullary necrosis

ICD10
N11.1 Chronic obstructive pyelonephritis
N11.8 Other chronic tubulo-interstitial nephritis
N11.9 Chronic tubulo-interstitial nephritis, unspecified

Clinical/Surgical Pearls

For best determination of renal function the bladder should be empty and kidneys unobstructed (ie, ureteral stone if large stones).

PYELONEPHRITIS, EMPHYSEMAOUS

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

BASICS

DESCRIPTION
• Acute necrotizing infection of the renal parenchyma and perirenal tissues caused by gas-forming organisms
  – Onset may be acute or insidious
  – Course is potentially life threatening (mortality: 11–42%)
• 1st report in 1898
  >200 reported cases

EPIDEMIOLOGY
Incidence
• All documented cases in adults
  – Most patients >60 yr old
  – Bilateral cases, unusual but reported (L > R)
Prevalence
N/A

RISK FACTORS
• Diabetes mellitus (DM) (up to 95%)
  – Especially with poor glycemic control
• Urinary tract obstruction
  – Urinary calculi
  – Papillary necrosis
  – Neoplasm
  – Immunosuppression
Genetics
N/A

PATHOPHYSIOLOGY
• Poorly understood
• Impaired host response allows microorganism proliferation
• Hypothesized that elevated tissue glucose levels provide substrate for microorganisms
  – Bacterial fermentation of sugar produces carbon dioxide
  – Low oxygen tension allows urinary tract infection to proceed
• E. coli is primary causative organism (70–90%)
  – Klebsiella, Proteus, Staphylococcus, and coagulase-negative Staphylococcus are less common
  – Candida, Entamoeba histolytica, and Aspergillus famigatus are rare causes

ASSOCIATED CONDITIONS
• Alcohol abuse
• Diabetic ketoacidosis
• Immunocompromised states, including transplant patients
• Impaired renal function
• Malnutrition
• Urinary tract obstruction, including urinary calculi, papillary necrosis, or neoplasm

GENERAL PREVENTION
• Effective glycemic control in diabetes mellitus (DM)
• Adequate treatment of pre-existing pyelonephritis
• Prompt relief of urinary tract obstruction, if present

DIAGNOSIS

HISTORY
• Classic triad:
  – Fever, chills
  – Nausea, vomiting
  – Flank pain and/or abdominal pain
• Urinary frequency/urgency, dysuria
• Malaise
• Altered mental status
• History of DM, urinary calculus, and/or immunocompromise
• Pneumaturia absent unless infection involves collecting system

PHYSICAL EXAM
• Pyrexia
• Abdominal or flank tenderness
• Cough over flank (vague)
• Leukocyte, confluence, altered mental status
• Septic shock (tachycardia, hypotension)

LAB
• Complete blood count (CBC)
• Basic metabolic panel (BMP)
• Urinalysis
• Blood cultures
• Abdominal radiograph may show tissue gas in surrounding kidney
  – Foci of micro- and macroinfarctions
  – Glomerulosclerosis, arteriosclerosis, intrarenal vascular thrombosis, or papillary necrosis

DIAGNOSTIC TESTS & INTERPRETATION

Physeal:
• Ultrasound may show highly echogenic area
• Abdominal radiograph or CT scan (most sensitive and specific)
• Pyuria, bacteriuria, positive urine culture
• Blood cultures
• Bacteremia (isolated organism same as that in urine)

Imaging
• Abdominal radiograph may show tissue gas in parenchyma (nonspecific, low sensitivity)
• Renal ultrasound may show highly echogenic area with skin shadowing
• Computed tomography (CT) is imaging modality of choice (most sensitive and specific)
  – May see:
    – Absence of fluid or presence of streaky or mottled gas
    – Bubbly and localized gas in renal parenchyma, collecting system, and/or perirenal tissue
    – Rim-like or crescent-shaped gas distribution surrounding kidney
    – Gas in renal vein, inferior vena cava, or retroperitoneum
    – Urinary tract obstruction (seen in ~25% of cases)
• Contrast not necessary for diagnosis (and may be contraindicated in renal impairment)

CLASSIFICATION
• Class 1: Gas confined to collecting system
• Class 2: Gas confined to renal parenchyma without extension to extrarenal space
• Class 3A: Perinephric extension of gas or abscess
• Class 3B: Pararenal extension of gas or abscess
• Class 4: Bilateral emphysematous pyelonephritis or emphysematous pyelonephritis in a solitary kidney
  – Therapeutic and prognostic implications:
    – Class 1 and 2: Percutaneous drainage successful, low mortality
    – Class 3 and 4: Percutaneous drainage less successful, increased mortality

DIFFERENTIAL DIAGNOSIS
• Acute pyelonephritis
• Emphysematous cystitis
• Fistulous communication with gastrointestinal or respiratory tracts
• Sarcoïdosis (nodularization of urinary tract)
• Nephrectomy with urinary tract obstruction
• Renal abscess
• Xanthogranulomatous pyelonephritis

GENERAL MEASURES
• Rapid supportive measures:
  – Fluid resuscitation
  – Correction of electrolyte imbalances
  – Vasopressors as needed
  – Usually requires ICU status
• Indwelling urethral catheter to maximize urinary tract drainage and monitor urine output

TREATMENT

Alert
Emphysematous pyelonephritis is urologic emergency that requires prompt diagnosis and intervention to prevent morbidity and mortality.
ADDITIONAL TREATMENT

ADDITIONAL READING

ADDITIONAL READING

ADDITIONAL READING

PYELONEPHRITIS, XANTHOGRANULOMATOUS

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

PHYSICAL EXAM

- Fever
- Flank tenderness
- Palpable flank mass
- Rarely elevated BP
- Weight loss
- Less common hematuria

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Arteria 71%
- Leukocytosis 62%
- Pyuria 81%
- Urine culture: Proteus and E. coli are most common

Imaging
- CT is the 1st-choice imaging study
- MRI shows enlarged kidney with mass, usually diffused
- Ultrasonography: shows Hydronephrosis
- CT is the 1st-choice imaging study
- IV urogram shows nonvisualization in 30–80% of patients

DIAGNOSIS

BASICS

DESCRIPTION
- Xanthogranulomatous pyelonephritis (XGP) is an uncommon chronic destructive granulomatous process of renal parenchyma in association with long-term urinary tract obstruction and infection

RISK FACTORS
- Diabetes
- History of stones
- History of UTIs

GENETICS
- N/A

PATHOPHYSIOLOGY
- Stones
- Obstruction
- Infection

Microscopic findings:
- Fissure formation with extension of inflammatory response beyond kidney

ASSOCIATED CONDITIONS
- Diabetes
- Renal calculus, including staghorn (35%)
- Immunosuppression

GENERAL PREVENTION

Diagnose and follow up of known UTIs

DIAGNOSTIC PROCEDURES/SURGERY

Phenotypic signs:
- Fever, chills, flank pain, fatigue, anorexia
- Persistent bacteremia even after antibiotic therapy

Pathologic Findings:
- Diffuse involvement of the entire kidney occurs in 80–90% of cases
- Segmental involvement is much less common
- XGP commonly extends beyond the kidney and may:
  - Fibrosar, pyelocutaneous and unilobarated have been noted

TREATMENT

GENERAL MEASURES
- Antibiotics, culture specific if possible continued until urine cultures are negative
- Usually managed by nephrectomy
- Renal abscesses
- Renal lymphoma
- TB

MEDICATION

First Line
- Broad-spectrum antibiotics pending urine culture, such as amoxicillin 1 g q 8h and an aminoglycoside 40 mg/kg q12h

Second Line
- N/A
SURGERY/OTHER PROCEDURES
- Nephrectomy is the most common treatment
  - Diffuse inflammatory process
  - Nonfunctioning kidney
  - Concern for malignancy
  - Inflammatory reaction, nephrectomy can be technically difficult
- Partial nephrectomy in rare cases of segmental XGP
- Mechanical and antibiotic bowel prep is performed since XGP may involve any adjacent organs or tissues
- Drains should be placed in renal bed
- Laparoscopic nephrectomy has been shown to be safe without increasing complications but, again, difficult (6)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Percutaneous drainage with antibiotics (7)

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
- Preservation of renal function related to the function of the contralateral kidney
- Chance of recurrent stones is high

COMPLICATIONS
- Renal failure related to complications
- Wound infection
- An injury to adjacent organs can occur during nephrectomy
- Major vascular injury related to the inflammatory process
- Fistulas or abscesses postoperatively require drainage and antibiotic therapy
- Renal insufficiency related to the function of the contralateral kidney
- Recurrent stone formation

FOLLOW-UP
Patient Monitoring
- Urinalysis and urine culture
- Serum creatinine, CBC, liver enzymes repeated to follow for normalization
- Further radiographic studies depending upon the histopathology of the kidney specimen

Patient Resources
N/A

REFERENCES

CODES
ICD10
- B96.4 Proteus (mirabilis) (morganii) infection in conditions classified elsewhere and of unspecified site
- N90.00 Chronic pyelonephritis without lesion of renal medullary necrosis
- N91.60 Bladder obstruction, unspecified

CLINICAL/SURGICAL PEARLS
- Be suspicious in patients with fever, flank pain, and weight loss.
- Persistent OTI with adequate treatment is a warning.
- CT scan for diagnosis and extent of disease.
- XGP is primarily a surgically managed disease usually by nephrectomy with antibiotics critical to the management of this condition.
- Usually unilateral and frequently confused clinically and radiographically with renal cell carcinoma.
PYONEPHROSIS

Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION
- Pyonephrosis is a collection of purulent material in the renal collecting system
- Typically resulting from an underlying obstruction within the upper urinary tract (2)
- With concomitant urinary tract infection
- Considered a surgical emergency with drainage of obstructed collecting system necessary (1)

EPIDEMIOLOGY

Incidence
- True incidence is unknown
- Increased in patients with upper urinary tract obstruction

Prevalence
See above

RISK FACTORS

- Upper urinary tract obstruction
- History of prior urologic instrumentation
- Immunosuppressed patient
- History of prior urologic instrumentation
- History of prior urologic instrumentation
- Renal nuclear scan

ASSOCIATED CONDITIONS

- Pyelonephritis
- Pyelonephritis
- Xanthogranulomatous pyelonephritis
- Urothelial carcinoma (UC) of upper tracts
- Ureteropelvic junction obstruction (UPJO)

GENERAL PREVENTION

- Relief of underlying urologic obstruction
- Proper medical management of immunosuppression
- Identification of any anatomic urologic abnormality

DIAGNOSIS

HISTORY

- Fever
- Flank pain
- Clinical evidence of UTI

PHYSICAL EXAM

- CVI tenderness or without palpable abdominal mass (hydronephrotic kidney)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine culture of obstructed system
- Elevated C-reactive protein

Imaging

- CT scan of IV contrast
- MRU
- MRU
- MRI
- Ultrasonography

Pathologic Findings

- Ascertainment of obstructed system will usually show:
  - MRU
  - CT scan
  - MRU
  - Ultrasonography

DIFFERENTIAL DIAGNOSIS

- Neutrophilia/leukocytosis
- Xanthogranulomatous pyelonephritis
- Ureteropelvic junction obstruction (UPJO)
- Urothelial carcinoma (UC) of upper tracts
- Ureteral stricture
- Ureterocalculus
- Hydronephrosis

ALERT

- Patients may rapidly decline clinically and become septic.

Etiologies of obstruction (1)
- Stones and sloughed calculus
- In as many as 75% of patients
- Infectious adenocarcinoma of the renal pelvis
- Pregnancy
- Prolonged milk
- Metastatic retroperitoneal fibrosis—eg, abdominal tumors
- Renal tumors, testicular cancer, colon cancer
- Obstructing transitional cell carcinoma
- Ureteropelvic junction obstruction (UPJO)
- Obstructing ureteroceles
- Ureterohydronephrosis
- Chronic stasis of urine and hydronephrosis secondary to neurogenic bladder
- Urinary strictures
- Nephrolithiasis
- Nephrotic syndrome
- Tuberculosis
- Debris
- Hydronephrosis

Pathologic Findings

- May be useful for patients with impaired renal function
- Elevated C-reactive protein

IMAGING

- CT scan with IV contrast
- MRU
- Ultrasonography
- MRU
- MRI

Pathologic Findings

- May be useful for patients with impaired renal function
- Elevated C-reactive protein

IMAGING

- CT scan with IV contrast
- MRU
- Ultrasonography
- MRU
- MRI

Pathologic Findings

- May be useful for patients with impaired renal function
- Elevated C-reactive protein

IMAGING

- CT scan with IV contrast
- MRU
- Ultrasonography
- MRU
- MRI

**TREATMENT**

**GENERAL MEASURES**
- Drainage of obstructed collecting system is the mainstay of treatment
  - Antegrade nephrostomy tube placement
    - Indicated in the clinically unstable patient
    - Best for maximal decompression
  - Retrograde ureteral stent placement
    - Indicated in the stable patient able to tolerate general anesthesia
    - Best for maximal decompression
  - Treatment of source obstruction:
    - Once collecting system has been decompressed and appropriate antibiotic/antifungal therapy has been given for 2 wk
    - May include endoscopic, percutaneous, transurethral, laparoscopic, robotic, extracorporeal, or open approaches
    - Depends on the nature of obstruction (ie, stone, stricture) (1)
- Clinical feasibility of intervention

**MEDICATION**

**First Line**
- Broad spectrum intravenous antibiotics (ie, piperacillin and tazobactam, gentamicin, and ampicillin) and antifungals if clinically indicated for funguria
- Antibiotics can be focused once cultures result

**Second Line**
N/A

**SURGERY/OTHER PROCEDURES**
- Indication for nephrectomy is controversial
  - May be indicated if source of infection is not found
  - To exclude malignant etiology of obstruction
  - Lack of response to percutaneous drainage and IV antibiotics/antifungals
  - Poorly functioning kidney

**ADDITIONAL TREATMENT**

**Radiation Therapy**
N/A

**Additional Therapies**
N/A

**Complementary & Alternative Therapies**
N/A

**ONGOING CARE**

**PROGNOSIS**
- Good in patients who receive prompt diagnosis and therapy
- Most patients will improve 24–48 hr after drainage of obstructed renal collecting system
- Recovery of renal function is rapid

**COMPLICATIONS**
- Sepsis is the most common complication of delayed treatment
- Other complications of delayed treatment include:
  - Rupture of pyonephrotic kidney resulting in:
    - Generalized peritonitis
    - Renocolic fistula
    - Renoduodenal fistula
  - Sepsis
    - Septic shock
    - Fungal sepsis
  - Loss of renal function
- Complications from nephrostomy tube:
  - Blood transfusions
  - Hematoma
  - Nephrostomy tube replacement/revision
  - Increased risk of infection if nephrostomy is not performed when indicated

**FOLLOW-UP**

**Patient Monitoring**
- Treatment of underlying obstruction (ie, calculus, stricture, malignancy)
- Treatment and control of any predisposition to infection (ie, DM, HIV/AIDS, neurogenic bladder)

**Patient Resources**

**REFERENCES**

**ADDITIONAL READING**

**CODES**
- ICD9: 590.80 Pyelonephritis, unspecified
- N13.6 Pyonephrosis
- N28.89 Other specified disorders of kidney and ureter
- N39.0 Urinary tract infection, site not specified

**ICD10**
- N13.6 Pyonephrosis
- N28.89 Other specified disorders of kidney and ureter
- N39.0 Urinary tract infection, site not specified

**CLINICAL/SURGICAL PEARLS**
- Patients with pyonephrosis may be asymptomatic or present with a picture of an abscess with fever and chills
- Unilateral staghorn calculi, and fungus balls are the most common clinical causes of pyonephrosis.
PYURIA

Christina Carpenter, MD
Mark L. Jordan, MD, FACS

BASICS

DESCRIPTION
• Presence of WBCs in the urine
  • Normal WBCs in a urine specimen
    – Men > 2 WBC/hpf
    – Women ≤ 5 WBC/hpf
  • When seen with bacteriuria, suggests inflammatory response of ureteral (4, infection)
  • When seen without bacteriuria (sterile pyuria), raises suspicion for tuberculosis, partially treated UTI, stones, and/or malignancy

EPIDEMIOLOGY
When seen in a voided urine specimen, has an 80–95% sensitivity for detecting patients with a urinary tract infection (UTI)

RISK FACTORS
• Urinary tract infection (UTI)
• Bacteriuria
• Urinary tract stone
• Cystitis
• Pyelonephritis
• Interstitial nephritis
• Tuberculosis
• Cancer
• Drugs/medications (corticosteroids, nonsteroidal anti-inflammatory agents, diuresis)

PATHOPHYSIOLOGY
• Clean-catch midstream urine may contain contaminants (bacteria, squamous epithelial cells)
• Significant pyuria (at least 10 WBCs/mm³) is uncommonly seen in patients without true infection

ALERT
• 10% of all elderly women have significant pyuria without associated bacteriuria (1,2,4).
• Can be caused by bacteria in the urinary tract producing an inflammatory response
• Bacteria can colonize the genitourinary system in a retrograde fashion
• Certain bacteria are more frequently the cause of UTIs as they are more efficient at adhering to the mucosal cells of the urinary tract (eg, Escherichia coli)

ASSOCIATED CONDITIONS
• Bacteriuria
• UTI
• Pyelonephritis
• Nephrolithiasis

GENERAL PREVENTION
• Proper toileting habits
• Complete bladder emptying
• Adequate fluid intake (stone prevention)

DIAGNOSIS

HISTORY
• Common symptoms: Dysuria, frequency, urgency, malaise
• Fever (more common with upper tract infection)
• Hematuria (gross)
• Occasional
• More common in females
• Rare in children
• Physical presentations
  • Young patients
    – Difficulty with bladder training, urgency, incontinence
  • Abdominal discomfort, failure to thrive, fever, vomiting, jaundice
• Elderly
  • Incontinence, fevers, frequency, urgency
• May be asymptomatic
• History of recurrent childhood fevers—may imply frequent UTIs and potential congenital anomalies
• History of UTIs among female family members

PHYSICAL EXAM
• Suprapubic tenderness
• Costovertebral angle tenderness
• Suprapubic tenderness
• History of recurrent childhood fevers—may imply frequent UTIs and potential congenital anomalies
• History of UTIs among female family members

DIAGNOSTIC TESTS & INTERPRETATION

Lab
• Dipstick
  – Best screening tool
  – Leukocyte esterase (LE)
  – Produced by granulocytes that catalyze the hydrolysis of an indoxylcarbonic acid ester to indoxyl, which reacts with a diazonium salt to produce a purple color on the reagent strip
  – 75–96% sensitive for a culture-positive UTI (GFA)
• Sterile pyuria: Imaging to identify source/evaluate bladder pathology, obstruction, stone disease, and/or malignancy

DIAGNOSTIC PROCEDURES/SURGERY

• Localization of bacteria
  • Segmented urine specimen
  • Urinalysis/cultivation in OR
  • Immunologic/antibody studies
• Isotopic function studies
• Cystoscopy
• CT localization of indwelling abnormality responsible for bacteriuria/pyuria (4, abscess)

• CT: Localization of nidus/abnormality responsible for bacteriuria/pyuria (4, abscess)

DIFFERENTIAL DIAGNOSIS

• Pyelonephritis—acute, chronic pyelonephritis, xanthogranulomatous
• Recurrent urinary tract infection
• Interstitial cystitis
• Immunodeficiency
• Neoplasm
• Kidney stones
• Tuberculosis
• Chronic kidney disease
• Nephrotic syndrome
• Diabetic nephropathy
• Leukocyte esterase
• Indoxyl
• N-acetyl-β-D-glucosaminidase
PYURIA

**TREATMENT**

**GENERAL MEASURES**
- Identify cause of inflammatory response
- Direct treatment at cause of pyuria
- UTI is most commonly the origin

**MEDICATION**

**First Line**
- In infection, should be empiric until targeted therapy can be initiated based on culture results (4)
- See “Urinary tract infection (UTI), adult female,” “Urinary tract infection (UTI), adult male” and “Urinary tract infection (UTI), pediatric”

**Second Line**
- N/A

**SURGERY/OTHER PROCEDURES**
- Correct underlying abnormality
- Treat calculus
- Remove foreign body (eg, ureteral stent)

**ADDITIONAL TREATMENT**
- Bacteriuria with pyuria is treated as a UTI in children and premenopausal women
- Persistent or recurrent bacteriuria may require prolonged antibiotic treatment followed by chronic low-dose prophylactic antibiotics
- High-risk patients (children with congenital abnormalities, immunocompromised adults) may need chronic suppressive antibiotic treatment
- Postmenopausal women
  - May have chronic pyuria with mild bacteriuria
  - Require treatment only if symptomatic or if associated with complicating factors
- Diabetics, patients with obstructive uropathy, and immunocompromised patients may have additional requirements to address ongoing pyuria adequately

**ONGOING CARE**

**PROGNOSIS**
- Dependent upon etiology

**COMPLICATIONS**
- Ascending bacterial infections
- Urosepsis
- Renal failure
- Death

**FOLLOW-UP**

**Patient Monitoring**
- Repeat exam 2-wk post UTI treatment
- Urinalysis, urine culture
- Routinely screen asymptomatic individuals over the age of 65 years
- Routine periodic evaluation to check for recurrence of pyuria

**Patient Resources**
- www.UrologyHealth.org

**REFERENCES**

**ADDITIONAL READING**

**CODES**

ICD9 791.9 Other nonspecific findings on examination of urine

ICD10 N39.0 Urinary tract infection, site not specified

**CLINICAL/SURGICAL PEARLS**

- Absence of pyuria should lead the clinician to question a diagnosis of UTI.
- Sterile pyuria does not suggest a benign process.
- Persistent asymptomatic pyuria requires further workup, ie, cystoscopy, imaging.
- Atypical presentations in children, the elderly, and the immunocompromised require the clinician to maintain a high index of suspicion.
RECTAL INJURY DURING RADICAL PROSTATECTOMY OR RADICAL CYSTECTOMY
Debasish Sundi, MD
Misop Han, MD

BASICS

DESCRIPTION
• Rectal injury is a rare, potential complication of radical prostatectomy or radical cystoprostatectomy, with a reported incidence ranging from 0.1–1.7%.
  – Reported for radical prostatectomy: Retropubic, laparoscopic, and robotically assisted approaches.
  – Reported for radical cystectomy: Open and robotically assisted approaches.
• Intraoperative recognition of the rectal injury is paramount; this will allow primary repair in layers and minimize the chance of subsequent rectovaginal fistulas.
• Occasionally, the injury will not be identified until the postoperative period.

EPIDEMIOLOGY
Incidence
• The rate of rectal injury during urologic pelvic procedures varies by procedure and approach.
  – For radical prostatectomy, rectal injury rates are quite low, ranging from 0.1–0.5% (open retropubic, pure laparoscopic, or robot assisted).[2][C]
  – Rectal injury rates are higher for radical cystoprostatectomy (up to 1.7%)[3][C], and highest for perineal prostatectomy (8–11%)[4][C]
Prevalence
• Extrapolating from the number of procedures performed annually in the United States, the prevalence of rectal injury for radical prostatectomy ranges from 85–400 cases per year, and for radical cystectomy, up to 150 cases per year.

RISK FACTORS
• History of pelvic radiation therapy or prior pelvic surgery
• Genetics
  – N/A

PATHOPHYSIOLOGY
• N/A

ASSOCIATED CONDITIONS
• Prior pelvic radiation or surgical procedures may increase the risk of rectal injury.
• Extensive transurethral resection of bladder floor for urethral carcinoma
• Inflammatory bowel disease
• Locally advanced malignancy

GENERAL PREVENTION
• Adequate intraoperative hemostasis to aid visualization.
• Bowel preparation has not been proven to reduce the risk of intraoperative bowel injury but may limit contamination in the event of an injury.
• Placement of a rectal tube at the start of the procedure may aid in the identification of the rectal wall in difficult cases (ie, salvage prostatectomy following radiation).
• Careful identification of the anterior and posterior layers of Denonvilliers fascia will aid in avoiding rectal injury.

DIAGNOSIS
HISTORY
• After removal of the specimen (open surgery), inspection of the surgical bed using posterior traction to efface folds of tissue will typically reveal a rectal injury by direct visualization.
• Obtaining good hemostasis will aid visualization.
• Copious irrigation of the pelvis with sterile saline may also reveal air bubbles emanating from the rectal vault.[2][C]
• Symptoms may include abdominal or pelvic pain; nausea and vomiting may also be present.

PHYSICAL EXAM
• Postoperative manifestations may include exam findings that may indicate tenderness to palpation, fever, tachycardia, hypotension, ileus.[2][C]

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Acute injury may not manifest any lab abnormalities.
• Lab workup postoperatively may be unrevealing.
• These patients’ GI tracts can be brought back in continuity if a cystogram and/or Gastrografin enema are negative in 2–3 mo. If these patients have persistent fistulas, they should be surgically repaired with a transvesical advancement flap.[2][C]

Imaging
• Pelvis CT ± cystourethrography
  – Free air in pelvic and/or peritoneal spaces
  – Contrast communicating between rectum and bladder

TREATMENT
GUT CONNECTING INJURY
• After removal of the specimen (laparoscopic or robotic surgery) from the prostatic fossa, a suspected rectal injury can be confirmed by flooding the pelvis with saline irrigation and gently insufflating the rectum with air injected via a Foley catheter.
• A rectal enterotomy will be evident by air bubbling through the incision.

Pathologic Findings
• A through-and-through injury will involve both the rectal serosa and mucosa.

DIFFERENTIAL DIAGNOSIS
• Intraoperative differential diagnosis is limited.
• Postoperative differential includes:
  – Small bowel or large perforation (iatrogenic)
  – Colonic perforation secondary to pathologic distension such as in colonic pseudoobstruction, or Ogilvie syndrome
  – Pelvic abscess

MEDICATION
• When a rectal injury is diagnosed postoperatively, management depends on the patient’s clinical picture.
• Patients who are minimally symptomatic and have a small injury radiographically may be initially managed conservatively by indwelling urethral catheter with reassessment by cystoscopy after 2–3 mo.[3][C]
• The 50 patients who are symptomatic, septic, or have a history of prior pelvic radiation should be diverted with an end colostomy.[1][C]
• These patients’ GI tracts can be brought back in continuity if a cystogram and/or Gastrografin enema are negative in 2–3 mo. If these patients have persistent fistulas, they should be surgically repaired with a transvesical advancement flap.[2][C]

First Line
• 7–14 days of antimicrobial therapy.[4][C]
  – Antibiotic regimen should cover both gram negatives and anaerobes (such as Bacteroides and metronidazole)

Second Line
• N/A

EPIDEMIOLOGY
Incidence
• The rate of rectal injury during urologic pelvic procedures varies by procedure and approach.

RECTAL INJURY DURING RADICAL PROSTATECTOMY OR RADICAL CYSTECTOMY

SURGERY/OFFER PROCEDURES
- When a rectal injury is diagnosed intraoperatively, it should be repaired immediately, closing the rectal mucosa and skin in separate layers.
- Suture choice includes mucosal layer with 3-0 chronic and the serosa with 3-0 silk or other suitable alternatives (1).
- An additional flap of unvascularized tissue (omentum or peritoneum) should be interposed between the rectal repair and the bladder/urethra. Immediate repair minimizes the risk of subsequent rectourethral fistula.
- If a rectourethral fistula does form in spite of immediate repair, management options are conservative treatment via Foley catheterization or surgical repair via diverting colostomy and, if necessary, a transanastomotic advancement flap (2).

ADDITIONAL TREATMENT
Radiation Therapy
N/A
Additional Therapies
N/A
Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Among patients undergoing immediate intraoperative repair, there is a 12.5% incidence of subsequent rectourethral fistula (2).
- Rectal injuries of increasing length are associated with a higher risk of rectourethral fistula, as are those recognized and repaired in delayed fashion.

COMPLICATIONS
- Need for temporary colostomy diversion
- Rectourethral fistula
- Wide excision rectourethral fistula after radical prostatectomy: incontinence (1).
- Sepsis

FOLLOW-UP

Patient Monitoring
- After repair, routine monitoring on a regular surgical floor with daily labs is appropriate.
- Prior to routine Foley catheter removal after radical prostatectomy, perform cystogram to rule out fistula at 14 days after surgery.
- If rectourethral fistula is demonstrated, continue Foley catheter, as resolution of fistula with period of catheterization up to 9 wk has been demonstrated.

Patient Resources
None

REFERENCES

ICD9
- S36.60XA Unspecified injury of rectum, initial encounter
- N36.0 Urethral fistula
- K91.72 Acc pnctr & lac of a dgstv sys org during oth procedure
- 536.60XA Unspecified injury of rectum, initial encounter

CLINICAL/SURGICAL PEARLS
- Rectal injury during radical urologic pelvic surgery is a rare but serious complication.
- This injury can occur during open, laparoscopic and robotically assisted laparoscopic pelvic surgery.
- When recognized preoperatively, immediate primary repair assures the best outcomes.
- When immediate repair is not possible or contraindicated, the patient may be temporized with a diverting colostomy until the rectal injury heals, and the GI tract can be brought back into continuity.
- Rectourethral fistula is a delayed complication of rectal injury repair, the chance of which can be minimized with immediate recognition and repair of rectal injury.

RENAL AND PERIRENAL ABSCESS
Mary K. Powers, MD
Raju Thomas, MD, MHA, FACS

DESCRIPTION

- Renal abscess (pyonephrosis): Collection of purulent material confined to the renal parenchyma
- Perirenal abscess: Extension of an acute cortical abscess into the perirenal space, confined by Gerota fascia
- Psoas/perirenal abscess: Results from rupture of a perinephric abscess through Gerota fascia into the psoas space

EPIDEMIOLOGY

Incidence

Perinephric and renal abscesses are uncommon but potentially lethal complications of UTI.

Prevalence

- 2/3 of gram-negative abscesses are associated with renal calculi or kidneys with poor function
- Premature women with uncontrolled bacteriuria are associated with a higher incidence of pyelonephritis and subsequent diagnosis of abscess
- Renal infection is among the most common sites for potentially lethal complications of UTI

RISK FACTORS

Diabetes mellitus, polyplastic kidney disease, hemodialysis, necrotizing bladder, IV drug users, tuberculosis, recurrent urinary tract infection and/or extrapulmonary disease in patients with TB

Genetics

N/A

PATHOPHYSIOLOGY

- Gram-negative organisms have been implicated in the majority of adults with renal abscesses
- Escherichia coli, Proteus mirabilis, and Staphylococcus aureus account for the majority of infections in descending order of occurrence (7)
- Hematogenous renal seeding by gram-negative organisms may occur, but this is not likely to be the primary pathway for gram-negative abscess formation
- Hematogenous renal seeding: Skin infection with gram-positive organisms, IV drug abuse, immunocompromised status
- Ascending infection associated with tubular obstruction from prior infections, urocutaneous reflex, or calculi appears to be the primary pathway for the establishment of gram-negative abscesses

ASSOCIATED CONDITIONS

See “Risk Factors” above

GENERAL PREVENTION

Increased clerical suspicion, prompt recognition, and treatment of infection, especially in the face of obstruction in high-risk patients

DIAGNOSIS

HISTORY

- Significant chronic or acute illnesses including diabetes, neurogenic bladder dysfunction, chronic renal failure, hemodialysis, and polyplastic renal disease
- Renal CaCulii
- IV drug abuse
- Gram-positive source of infection 1–8 wk before the onset of urinary tract symptoms
- Previous infection can occur in any area of the body (eg, skin lesions, dental infections)
- Patients with UTI and abdominal or flank mass
- Persistent fever with suspected genitourinary source after 3–5 days of antimicrobial therapy

PHYSICAL EXAM

- Elevated temperature
- CVI or flank tenderness
- Abdominal and/or flank mass
- Distended or palpable bladder
- Look for skin carbuncles or dermatologic evidence of IV drug abuse
- Heart murmurs

DIAGNOSTIC TESTS & INTERPRETATION

- Urine analysis:
  - Pyuria and bacteria often present, although pyuria/bacteriuria may not be evident unless the abscess communicates with the collecting system
  - Sterile pyuria often seen with TB
- CBC:
  - Patients typically have marked leukocytosis
- Urine culture:
  - When abscesses contain gram-negative organisms, urine culture often demonstrates the same organism isolated from the abscess
  - Since gram-positive organisms are most commonly blood borne, urine culture in these cases typically show no growth or a microorganism different from that isolated from the abscess
  - Catherized urine collection recommended for female patients
- Blood cultures:
  - Gram-negative organisms are most commonly cultured
  - Gram-positive organisms are not routinely similar to those cultured from abscess

LAB

- Serum creatinine:
  - Common findings include an echo-free or hypoechoic renal mass
  - Absence of psoas shadow on affected side
  - Bubbles of extraluminal gas can be seen surrounding the kidney in large perirenal abscesses

DIAGNOSTIC TESTS/SURGERY

CT or ultrasound

- Differentiation between early renal abscess and acute pyelonephritis is difficult due to small size
- Abdominal CT:
  - Diagnostic procedure of choice
  - Can often delineate the route of spread of infection into surrounding tissues
  - Abscesses are characterized by well-defined borders and after contrast agent enhancement
  - Acute findings include renal enlargement and focal, rounded areas of decreased attenuation
- Chronic findings include obliteration of adjacent tissue planes, thickening of Gerota (perirenal) fascia, a round or oval parenchymal mass of low attenuation, and a surrounding inflammatory wall of slightly higher attenuation that forms a ring when the scan is enhanced with contrast material (ring sign)

- See Figure 1, Renal Abscess
- IV urography (IVP performed):
  - Abnormal in up to 80% of patients, although findings often are nonspecific
  - Generalized enlargement of involved renal unit with distortion of renal contour and collecting system
- Abscesses are characteristically well defined both on nonenhanced and contrast-enhanced scans

- See Figure 1, Renal Abscess

- Differentiation of emphysematous pyelonephritis which may require urgent surgical intervention. See Section I, Emphysematous pyelonephritis

DIAGNOSTIC PROCEDURES/SURGERY

CT or US-guided needle aspiration may be necessary to differentiate an abscess from a hypernephroma or tumor. Aspirated material can be collected for culture to guide appropriate antimicrobial therapy.

- Percutaneous drainage may be left in place and clinical course can be evaluated

PATHOLOGIC FINDINGS

Abscess fluid will demonstrate neutrophils and gram stain will reveal bacteria
**Differential Diagnosis**
- Pyelonephritis (S)
- Pyonephrosis
- Xanthogranulomatous pyelonephritis
- Empyema pyelonephritis
- Renal TB
- Local perforation with retroperitoneal spread of infection

**Treatment**

**General Measures (3,4)**
- Hospitalization with initiation of IV antibiotics and fluid resuscitation.
- Suspected pyelonephritis treated with antibiotics for 48–72 hr without significant improvement requires radiographic evaluation to rule out obstruction and/or abscess formation.
- Recent evidence indicates that for very small (<3 cm abscesses), careful observation and IV-tailed antimicrobial agents may obviate surgical procedures.
- Abscesses 3–5 cm in diameter and smaller abscesses in immunocompromised hosts or those that do not respond to antimicrobial therapy should be drained percutaneously.
- Surgical drainage, however, currently remains the procedure of choice for most renal abscesses (>5 cm in diameter or if perirenal extension of abscess occurs.
- Observation, if present, must be reviewed.

**Medication**

**First Line**
- Antibiotic therapy. May prevent surgical intervention unless abscess involves periureteral space.
- Initiate empiric treatment with fluid resuscitation and broad-spectrum IV antibiotics.
  - Third-generation cephalosporins
    - Ceftriaxone—1–2 g IV/Q12h
  - Aminoglycosides
    - Gentamicin—1.7 mg/kg IV/Q8h
    - Amikacin—7.5 mg/kg IV/Q12h
  - Piperacillin/Tazobactam—3.375 g IV/Q6h
  - IV antibiotics until sterile for 48–48 hr, switch to PO for at least 2 wk based on culture.

**Second Line**
- For a suspected hematogenous source, expand coverage to include penicillin-resistant Staphylococcus.
  - Vancomycin—1 g IV/Q12h

**Surgery/Other Procedures**
- Standard treatment for renal abscesses >5 cm or those that fail to respond to percutaneous drainage and if IV antibiotic therapy has been rapid and effective.
- Relief of coexisting obstruction is mandatory.
- Primary treatment remains drainage for all perinephric abscesses.
- Nephrectomy may be required for adequate treatment if medical therapy/Incision and drainage fails.

**Additional Treatment**

**RADIATION THERAPY**
- N/A

**Additional Therapies**
- CT or US-guided placement of percutaneous drains with concurrent IV antibiotic therapy is currently an accepted method of treatment for abscesses 3–5 cm in size and smaller abscesses in immunocompromised patients who fail to respond to medical therapy.

**Complementary & Alternative Therapies**
- N/A

**Ongoing Care**

**Prognosis**
- Perinephric abscess is historically associated with mortality rates approaching 39–50%.
- Recent series with prompt implementation of IV antibiotics and subsequent percutaneous or surgical drainage report mortality rates of 3–12%.

**Complications**
- Delay in diagnosis is associated with higher mortality rate.
- Delay in diagnosis and treatment is associated with loss of renal function and, in rare circumstances, perithoracic fissures to the pleura, colon, skin, etc.

**Follow-Up**

**Patient Monitoring**
- Address the underlying medical conditions to prevent recurrent infections.
- Repeat radiographic studies to confirm complete resolution.
- Extended antibiotic therapy is often required.

**Patient Resources**
- Medline Patient Information:
- Urology Care Foundation Patient Guide:
  - http://www.urologyhealth.org/urology/index.cfm/article=18

**References**

**Additional Reading**

**Clinical/Surgical Pearls**
- Abscesses >3 cm can be managed with medical treatment initially.
- Continued fevers require surgical drainage of abscess.
- Include gram-positive antibiotic coverage if suspect hematogenous spread (IV drug use).
**Ganesh V. Raj, MD, PhD, FACS**

**RENAH ANGIO MYOLIPOMA**

**Casey Allison Steideman, MD**

**Ganesh V. Raj, MD, PhD, FACS**

**DIAGNOSIS**

**HISTORY**
- Most asymptomatic, discovered incidentally
- Occasionally diagnosed by flank pain, hypertension, and spontaneous hemorrhage
- History of LAM, TSC
- GI complaints due to mass effect
- Hematuria, hypertension, anemia

**PHYSICAL EXAM**
- Hypertension, or hypotension (in the setting of hemorrhage)
- TSC: Mental retardation, adenoma sebaceum, ungual/subungual fibromas, lung disease
- Flank pain/tenderness
- Up to 50% of patients who are symptomatic may have a palpable mass

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Anemia
- Gross/micro hematuria
- Renal insufficiency
- Genetic testing if TS is suspected

**Imaging**
- CT: AML is commonly diagnosed on CT scans that reveal solid masses with areas of fat density (Hounsfield units below —20), most reliable imaging modality; IV contrast not necessary
- 10 mg once daily with or without food
- Approved in adults with renal AML and TSC not requiring immediate surgery
- Most TSC-associated disease manifestations, such as skin manifestations, pulmonary LAM, cardiac rhabdomyomas, and epilepsy
- Oral: Everolimus (4)
- Fstedlin (4)
- Approved in adults with renal AML and TSC not requiring immediate surgery
- May benefit other TSC-associated disease manifestations, such as skin manifestations, pulmonary LAM, cardiac rhabdomyomas, and epilepsy
- An inhibitor of mammalian target of rapamycin (mTOR), a serine-threonine kinase, downstream of the PI3K/AKT pathway

- **DIFFERENTIAL DIAGNOSIS (2)**
  - Renal masses:
    - Oncocytoma
    - Renal and retroperitoneal liposarcoma
    - Renal cell carcinoma
    - Renal cyst
    - Renal lipoma
    - Sarcoma (including fibrosarcoma, leiomyosarcoma, and liposarcoma)
  - Neurofibroma
  - Upper-tract urothelial carcinoma
  - Wilms tumor
  - Xanthogranulomatous pyelonephritis
  - Renal/retroperitoneal hemorrhage:
    - Atherosclerotic malformation
    - Coagulopathy
    - Hemorrhage of other renal mass such as renal cell carcinoma
    - Iatrogenic
    - Traumatic injury
    - Vasculitis

**GENERAL MEASURES (3)**
- Benign renal masses, rarely transform to malignant entities
- Observation unless large, or symptomatic

**MEDICATION**

**FIRST LINE**
- Medical management is not currently standard

**SECOND LINE**
- Everolimus (4)
- Approved in adults with renal AML and TSC not requiring immediate surgery
SURGERY/OTHER PROCEDURES
- Indications: Diagnostic uncertainty, hemorrhage causing significant symptoms, pain, hematuria, risk of rupture.
- Asymptomatic AML: <4 cm:
  - Observation with serial imaging at 12-mo intervals
  - Treatment should be considered; observation with serial imaging
  - The risk of spontaneous hemorrhage appears greatest in masses <4 cm
  - Women of childbearing age may consider proactive treatment
- Symptomatic AML: >4 cm:
  - Selective arterial embolization or nephron-sparing surgery
  - Acute hemorrhage:
    - Initially treated with embolization (stabilizes patient and often eliminates need for more intervention)
    - If explored emergently, total nephrectomy usually necessary

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Limited reports of treatment using cryoablation and radiofrequency ablation
- In patients with LAM or TS, mTOR inhibitors such as everolimus (mTOR inhibitor) can shrink large masses by 30%.
- Limited reports of treatment using cryoablation and radiofrequency ablation
- Acute hemorrhage:
  - Symptomatic AML/lesion
  - Asymptomatic AML

Indications: Diagnostic uncertainty, hemorrhage due to complications and recurrence risk.
- Women of childbearing age may consider conservative management: Serial imaging (usually >4 cm)
- Observation for small masses, consider embolization
- Diagnosis is usually made by imaging.
- Larger lesions have increased risk of spontaneous hemorrhage.

ADDITIONAL READING

RENSA F/P Y

MORE INFO
• Benign renal tumor characterized by presence of vascular, muscle, and adipose components.
• Larger lesions have increased risk of spontaneous hemorrhage.
• Diagnosis is usually made by imaging.
• Observation for small masses, consider embolization for larger masses.
• Everolimus (mTOR Inhibitor) can shrink large multifocal lesions in patients with tuberous sclerosis (TS) and lymphangiomyomatosis (LAM).

REFERENCES

CODES
ICD9
• 239.0 Benign neoplasm of kidney, except pelvic.

ICD10
• D17.71 Benign epithelioid neoplasm of kidney.
• N28.89 Other specified disorders of kidney and ureter.
• Q85.1 Tuberous sclerosis.

CLINICAL/SURGICAL PEARLS
• Benign renal tumor characterized by presence of vascular, muscle, and adipose components.
• Observation for small masses, consider embolization for larger masses.
• Everolimus (mTOR Inhibitor) can shrink large multifocal lesions in patients with tuberous sclerosis (TS) and lymphangiomyomatosis (LAM).
RENAL ARTERY STENOSIS/RENOVASCULAR HYPERTENSION

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

**BASICS**

**DESCRIPTION**
- Renal artery stenosis (RAS) refers to anatomic vascular lesion that causes decreased blood flow to the kidney
- May not be associated with hypertension (HTN)
- May be atherosclerotic in nature (atherosclerotic renal artery stenosis or ARAS)
- Rarely caused by fibromuscular dysplasia (FMD)
- Renovascular HTN (RVH) refers to HTN that is caused by renal hypoperfusion and is reversed by correction of the lesion or nephrectomy

**EPIDEMIOLOGY**

- **Incidence**
  - RVH found incidentally
  - 20% of patients with aortic occlusive disease
  - 41% of patients with diabetes
  - 7% of asymptomatic normotensive adults
  - 1% of hypertensive patients

- **Prevalence**
  - RVH diagnosed in hypertensive patients

**RISK FACTORS**
- Atherosclerosis
- Diabetes
- CAD
- Advanced age

**GENETICS**
- N/A

**PATHOPHYSIOLOGY**

- Atherosclerosis
  - Accounts for 70% of all RAS
  - Nerves and arterial endothelium
  - May cause high-grade stenosis

- CAD
  - Common cause of RAS
  - Accounts for 70% of all RAS

- Diabetes
  - 7% of asymptomatic normotensive adults
  - 20% of patients with coronary artery disease (CAD)

- Advanced age
  - 65 yr (1)

**ASSOCIATED CONDITIONS**

- High-grade retinopathy
- Atherosclerosis
- Diabetes
- CAD
- Renal vascular disease

**GENERAL PREVENTION**

- Reduction of risk factors for cardiovascular disease and diabetes

**DIAGNOSIS**

**HISTORY**

- Onset of HTN after age 50
- No family history of HTN
- Difficult-to-control HTN, on multiple antihypertensives
- Increase in serum creatinine with use of ACE inhibitors or angiotensin receptor blockers (ARBs)

**PHYSICAL EXAM**

- Blood pressure measurement
- Abdominal exam with auscultation for bruit
- Retinal exam

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Lab**
  - Plasma renin activity (PRA)
  - By itself, not diagnostic of RAS or RVH
- **Captopril test**
  - Useful for excluding RVH
  - Diuretics and ACE inhibitors stopped 1 wk prior
  - PRA measured before and 1 hr after 25-mg dose of captopril
  - Positive test if postdose PRA > 12 ng/mL/h, absolute increase of PRA > 10 ng/mL/h, 4-fold increase in PRA over baseline
  - Not appropriate in children or in patients with anemia

- **Imaging**
  - Angiography is gold standard
  - Highly sensitive and specific (99%)
  - Provides detailed anatomy, and allows for discrimination between FMD subtypes
  - Allows for simultaneous endovascular treatment
  - Usually bilateral
  - Accounts for 10% of FMD

- **Typically performed in patients with high suspicion for RVH**
- Captopril renography
  - Keep well hydrated on a liberal salt diet
  - Off ACE inhibitors for 3–5 days prior to exam
  - PRA measured before and 1 hr after captopril dose
  - Diagnostic criteria for RVH: Delay in maximal activity > 11 min, asymmetrical peak activity, cortical retention of isofluorolof, significant decrease in glomerular filtration rate
  - recommended as initial diagnostic intervention in patients with low- to moderate suspicion for RVH

- **Arteriography**
  - Positive diagnostic criteria: Peak systolic velocity > 120 cm/s, ratio of diameter of renal artery to aorta > 3.5
  - Invasive, noninvasive, but quality of study is operator dependent

- **Magnetic resonance angiography (MRA)**
  - May be more sensitive than ultrasound or renography, but inferior to conventional angiography
  - Poorly visualizes distal arteries
  - Contraindicated in patients with renal insufficiency (12)

- **Computed tomography angiography (CTA)**
  - Uses potentially nephrotoxic contrast agents
  - More widely available and cost-effective compared to MRA
RENAL ARtery STENOSIS/RENOVASCULAR HYPERTENSION

Diagnostic Procedures/Surgery
- Renal angiography
- Renal vein renin sampling
  - Useful in determining which kidney is primary contributor to RVR in patients with bilateral lesions

Pathologic Findings
- Renal biopsy indicated in patients with creatinine >4 mg/dL.
  - Tubular atrophy, interstitial fibrosis, arteriosclerosis indicate functional recovery may be possible
  - Widespread glomerular hyalization indicates irreversible injury

DIFFERENTIAL DIAGNOSIS
- Acute aneurysm
- Essential HTN
- Functional renal adenoma
- Intrarenal renal disease
- Renal artery aneurysm

TREATMENT

GENERAL MEASURES
- Recognition of underlying cause is critical in guiding management
- Smoking cessation
- Weight loss
- Reduction of risk factors for cardiovascular disease and diabetes

MEDICATION

First Line
- ACE inhibitors/ARBs: Improves HTN in 96% of patients with RVR. May not prevent progression of atherosclerotic lesions.
  - Captopril: 25-50 mg PO BID-TID
  - Lisinopril: 10–40 mg PO QD
  - Losartan: 25–100 mg PO divided QD-BID
  - Valsartan: 20–80 mg PO QD
  - Aspirin 81 mg PO QD
  - Statins

Second Line
- Thiazide diuretics
- Loop diuretics
- Calcium channel blockers
- P-blockers

SURGERY/OTHER PROCEDURES
- Surgical intervention recommended for patients with high-grade stenosis, bilateral disease, solitary kidney, declining renal function, pulmonary edema, congestive heart failure (3)
  - Angioplasty with or without endovascular stenting
  - Percutaneous access through common femoral artery
  - Selective angiography performed
  - ≥70% stenosis treated with angioplasty and deployment of balloon-mounted stent
  - Angioplasty without stenting is associated with increased risk of restenosis
  - One recent clinical trial suggests that the addition of renal artery stenting to comprehensive, multifaceted medical therapy did not confer a significant benefit (4)
  - Anticoagulant (heparin or saphenous vein)
  - Necropsy (especially in patients with a poorly functioning ipsilateral renal unit)

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies
- Treatment of concomitant disease
  - Antiplaque agents
  - Statins
  - Smoking cessation
  - Weight loss

Complementary & Alternative Therapies
- Symptomatic renal denervation using radiofrequency ablation is investigational at the present time, but shows promise (5)

ONGOING CARE

PROGNOSIS
- Untreated disease, except for medial fibroplasia, is often progressive and can result in renal functional loss

COMPlications
- Functional loss, worsening HTN, pulmonary edema, congestive heart failure in untreated patients
- Endovascular interventions: Access site hematomas, renal artery dissection, thrombosis, contrast-induced nephropathy
- Surgical interventions: Hemorrhage, wound infection, hemotoma, anesthetic complications

FOLLOW-UP
- Patient Monitoring
  - High-risk patients and those on medical therapy should be observed with serial metabolic and renal function studies in addition to Doppler ultrasonography

Patient Resources

REFERENCES

CODES

ICD9
- 443.90 Diabetes with renal manifestations, type II or unspecified type, not stated as uncontrolled
- 405.91 Unspecified renovascular hypertension

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- HTN, Urologic Considerations
- Renal Artery Aneurysm
- Renal Artery FMD
- Renin, Plasma and Renal Vein
- Renal Artery Stenosis Imaging: O

CLINICAL/SURGICAL PEARLS
- RVR HTN is caused by significant stenosis of the renal artery and is reversed by correction of stenosis or nephrectomy.
- Renal angioplasty remains gold standard for diagnosis.
- With the exception of medial fibroplasia, untreated RVR disease often leads to progressive renal functional loss.
RENAL CAPSULAR NEOPLASMS

Mathew C. Raynor, MD
Raj S. Pruthi, MD, FACS

**BASICS**

**DESCRIPTION**
- Predominantly mesenchymal neoplasms arising from the renal capsule encompassing a wide variety of cell progenitors:
  - Tumors can be composed of fibrous, smooth muscle, vascular, adipose, nerve, or other tissue differentiation.
  - Encompasses benign and malignant neoplasms.

**EPIDEMIOLOGY**
- **Incidence**:
  - Very rare tumors.
  - Represent up to ~1.5% of all surgically treated benign renal masses (1).
  - Incidentally found at autopsy in up to ~5% of cases (1).
  - Similar gender preference.

- **Prevalence**:
  - Unknown, due to rarity of tumor.

**RISK FACTORS**
- None known.
- Increased cross-sectional imaging use may identify incidental mass.

**PATHOPHYSIOLOGY**
- **Benign**:
  - Leiomyoma, hemangiopericytoma, hemangioma, lymphangioma, lipoma, fibroma, myxoma.
  - Solitary fibrous tumor.
- **Malignant**:
  - Leiomyosarcoma, malignant fibrous histiocytoma, fibromyxoid sarcoma, hemangiosarcoma, liposarcoma, fibrosarcoma.

**ASSOCIATED CONDITIONS**
- Some renal hemangiomas may be associated with Sturge–Weber or Klippel–Trénaunay syndromes (1).

**GENERAL PREVENTION**
- No preventive strategies identified.

**DIAGNOSIS**

**HISTORY**
- Usually asymptomatic or discovered incidentally.
- May present with hematuria or flank pain.
- Weight loss, anorexia, malaise, or bone pain may signify metastatic disease.

**PHYSICAL EXAM**
- Usually normal.
- Rarely, flank mass may be palpable.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urinalysis:
  - Microscopic hematuria may be identified, but usually normal.
- CBC:
  - Anemia may be present with advanced disease or bleeding mass.
- Serum chemistries usually normal.

**Imaging**
- CT or MRI with and without contrast:
  - May show enhancing mass arising from the kidney.
  - Indistinguishable from renal cell carcinoma in most cases.
  - Presence of fat may signify angiomyolipoma, lipoma, or liposarcoma.
  - May also be useful for evaluating for metastatic disease.

**Diagnostic Procedures/Surgery**
- Core needle biopsy:
  - May be used in cases of suspected renal malignancy or if active surveillance considered.
- Angiography:
  - May be utilized for bleeding lesions.
- Gross appearance usually hypovascular.
- Excise hemangiopericytoma, which is highly vascular.

**Pathologic Findings**
- Leiomyoma:
  - Firm, well-circumscribed, exophytic mass.
  - Microscopically, composed of spindle cells arranged in fascicles typical of smooth muscle.
  - Immunostaining positive for desmin, smooth muscle actin, and usually HMB-45 (1,2).
- Hemangiopericytoma:
  - Solid, encapsulated mass.
  - Microscopically, varied cell shapes and sizes with morphologic variability.
  - Immunostaining positive for vimentin, BCL2, CD99 and negative for S100, c-kit, and SMA (1,2).
- Lymphangioma:
  - Well-encapsulated, multilocular cystic mass.
  - Microscopically, communicating cysts lined with flattened endothelial cells.
  - Immunostaining positive for CD31 (1,2).
- Solitary fibrous tumor:
  - Well-encapsulated firm mass without necrosis, opt, or hemorrhage.
  - Microscopically, usually shows areas of spindle cells intermixed with hypocellular areas of fibrous tissue.
  - Immunostaining strongly positive for CD34 and HMB-45.
  - May also be positive for CD90 and CD117 and can be misclassified as hemangiopericytoma (1,2).
- Leiomyosarcoma:
  - Usually large circumscribed mass with areas of necrosis.
  - Microscopically, spindle cells with haphazard growth pattern, nuclear pleomorphism, mitoses, and necrosis.
  - Immunostaining positive for SMA, desmin, and calponin (1,2).
- Fibrosarcoma:
  - Large encapsulated mass.
  - Microscopically, elongated spindle cells with “Herringbone” pattern.
  - Immunostaining positive for vimentin.
  - Differentiates fibrosarcoma from sarcomatoid RCC and leiomyosarcoma (1,2).
- Malignant fibrous histiocytoma:
  - Solid, well-encapsulated mass.
  - Microscopically, proliferation of fibrohistiocytes.
  - Immunostaining positive for vimentin and CD68.

**REFERENCES**

**ABBREVIATIONS**

RCC: Renal cell carcinoma
CD31: VascularCAM
CD34: VascularCAM
CD90: VascularCAM
CD99: VascularCAM
HMB-45: VascularCAM
SMA: Smooth muscle actin
Desmin: Smooth muscle actin
Calponin: Smooth muscle actin
RENAL CAPSULAR NEOPLASMS

DIFFERENTIAL DIAGNOSIS
- Angiomyolipoma
- Renal cyst
- Cystic nephroma
- Juxtamedullary renal cell carcinoma
- Renal pseudotumour
- Spleen xenograft
- Teratoma
- Wilms tumor
- Xanthogranulomatous pyelonephritis

TREATMENT
GENERAL MEASURES
- Surgical excision is both diagnostic and therapeutic
- Multimodal therapy generally recommended for malignant tumors such as sarcoma

MEDICATION
First Line
- Chemotherapy may be beneficial for certain advanced renal capsular malignancies (sarcoma) and metastatic lesions
- Usually given in the adjuvant setting
- Targeted therapies may be beneficial in certain cases
- Sunitinib, sorafenib, bevacizumab active in angiosarcoma, solitary fibrous tumor, and hemangiopericytoma

SURGERY/OTHER PROCEDURES
- Surgical excision remains gold standard
  - Radical nephrectomy
  - Partial nephrectomy
  - Renal capsule margin should be excised with mass
  - Should be procedure of choice for patients with chronic kidney disease, when feasible
  - Active surveillance
  - Similar surveillance protocol for patients with small renal masses

ADDITIONAL TREATMENT
Radiation Therapy
- May be beneficial in cases of renal capsular sarcoma
  - Usually given in adjuvant setting

Additional Therapies
- Arterial embolization for bleeding masses

Ongoing Care

PROGNOSIS
- Surgical excision usually curative
- Renal capsular sarcoma has poor prognosis
  - Locally advanced disease is common
  - Recurrence and metastases common
  - Overall prognosis is poor, despite adjuvant chemoradiation
  - 5-yr overall survival — 15%-
  - Median survival 28 mo (4)

Complications
- Injury to adjacent organs
- Thromboembolic event
- Delayed bleed
  - ARF
  - Pseudoaneurysm
- Development of metastatic disease

Follow-Up
- Patient Monitoring
  - Periodic surveillance imaging
  - Serum chemistry panel and liver function tests

Patient Resources
- None due to rarity of disease

REFERENCES

ADDITIONAL READING
- Soft Tissue Sarcoma. NCCN Clinical Practice Guidelines in Oncology (www.nccn.org).

See Also (Topic, Algorithm, Media)
- Hemorrhage, Retroperitoneal and Perinephric
- Renal Capsular Neoplasms Image
- Renal Mass
- Renal Masses, Benign WHO Classification
- Renal Sarcoma, Adult and Pediatric

CODES
ICD9
- 189.0 Malignant neoplasm of kidney, except pelvis
- 223.0 Benign neoplasm of kidney, except pelvis
- 239.5 Neoplasm of unspecified nature of other genitourinary organs

ICD10
- C64.9 Malignant neoplasm of unspecified kidney, except pelvis
- D30.00 Benign neoplasm of unspecified kidney
- D49.5 Neoplasm of unspecified behavior of other genitourinary organs

CLINICAL/SURGICAL PEARLS
- Renal capsular neoplasms difficult to distinguish from RCC by imaging alone.
- Surgical excision (partial or radical nephrectomy) can be diagnostic and curative in most cases.
- Renal capsular sarcomas carry generally poor prognosis, despite adjuvant therapy.
Genetics history.

RISK FACTORS

Incidence

There are approximately 62,930 cases of RCC diagnosed each year; about 10% have IVTT.

Prevalence (T)

- RCC with IVTT is seen in 4–15% of cases.
- In 50% of these cases, IVTT only extends to the RV.
- Level II—IVC > 2 cm above RV.
- Level III—Suprahepatic/infrahepatic IVC/right atrium

EPILOGUE

PHYSICAL EXAM

- Flank/abdominal mass (2%)
- Constitutional symptoms including fatigue, weight loss, or paraneoplastic syndrome (9%)
- Flank/abdominal pain (17%)
- Flank/abdominal mass
- Constitutional symptoms including fatigue, weight loss, or paraneoplastic syndrome

DIAGNOSIS

HISTORY

- Presentation of patients with RCC with IVTT is similar to RCC without tumor thrombus, but those with tumor thrombus are more likely to be symptomatic.

- Up to 95% of patients with intracaval extension present with symptoms. It is an incidental finding in 23%.

- Symptoms include:
  - Hematuria (35%)
  - Flank/abdominal pain (17%)
  - Constitutional symptoms including fatigue, weight loss, or paraneoplastic syndrome (9%)
  - Flank/abdominal mass (6%)

- Physical exam findings can include:
  - Bilateral lower-extremity edema
  - Varicocele (right side)
  - Dilated superficial abdominal wall veins
  - Caput medusa

DIAGNOSTIC TESTS & INTERPRETATION

- Basic lab work is necessary for preoperative workup including:
  - Liver function tests
  - Complete blood count
  - Basic metabolic panel
  - Ultrasound

- Chest imaging (preferably CT) and bone scan should be ordered as part of staging workup

- Assessment of IVTT cephalad extension should be performed 7–14 days before surgery because it can affect the surgical approach and the need for bypass procedures

- Ultrasoundography and standard CT can be used to detect the presence of IVTT, but may not be sufficient for surgical planning

- MRI (T1-weighted images) is the gold standard imaging technique used to assess the cephalad extent of the IVTT, the degree of occlusion, and its relationship to liver, diaphragm, and atrium

- Multidetector CT (MDCT) can also be used in patients who are not candidates for MRI

SURGERY/OTHER PROCEDURES

- Surgery is the gold standard for the treatment of RCC with IVTT (2,3,4)
- Most common TKIs used preoperatively are sorafenib and sunitinib; may decrease tumor size

- Tumor felt not to be surgically resectable

- Cytoreductive nephrectomy with tumor thrombus development and propagation below the tumor may be considered for patients with IVTT to prevent bland thrombus growth and propagation below the tumor

- Anticoagulation (preoperatively) should be considered for patients with IVTT to prevent bland thrombus development and propagation below the tumor

- Contraindications to preoperative anticoagulation include smoking, obesity, hyper tension, family history

- General measures

- General measures

- Differential diagnosis

- Other tumors associated with IVTT include urothelial cell carcinoma, adenocarcinoma, and angioleiomyoma

- Diagnosis

- Incidence

- Risk factors for RCC with IVTT are the same for RCC

- General measures

- General measures

- Associated conditions

- Pulmonary embolus

- Bilateral lower-extremity edema

- Lower-extremity DVT

- Varicocele

- Caput medusa

- General prevention

- Modification of above risk factors for RCC

- General measures

- General measures

- Differential diagnosis

- Other tumors associated with IVTT include urothelial cell carcinoma, adenocarcinoma, and angioleiomyoma

- General measures

- General measures

- Treatment

- First line

- Anticoagulation (preoperatively) should be considered for patients with IVTT to prevent bland thrombus development and propagation below the tumor

- Mediastinal, subclavicular (if present), or thoracosabdominal incisions can be used

- Median sternotomy or thoracoabdominal approaches can be used for IVTT above the diaphragm

- Surgical procedures/surgery

- Surgery is the gold standard for the treatment of RCC with IVTT (2,3,4)

- Diagnostic findings

- All subtypes of RCC have been associated with IVTT

- Clear cell is the most common histologic subtype associated with IVTT
Level I Thrombus Specifics
- Milks the thrombus into the RV and take a side bite of the IVC using a vascular clamp making sure not to occlude IVC flow
- Incise the IVC and remove the thrombus and kidney under direct vision
- Overview the caval defect

Level II Thrombus Specifics
- Mobilize the liver and divide minor hepatic veins to expose the infrahepatic IVC
- Place flumetl transection or vascular clamps sequentially on the infrarenal vena cava, concomitant IVC and suprarenal vena cava above the thrombus
- Incise IVC, remove the thrombus and kidney
- Flush-exposed IVC with heparinized saline
- Suture caval, release vascular clamps

Level III-IV Thrombus Specifics
- A wide variety of surgical approaches have been described
- Clamping of the IVC at the level can compromise hemodynamic stability
- Cardiopulmonary bypass: Used for IIT above the diaphragm, maintains continuous arterial/venous blood flow during IVC occlusion
- Deep hypothermic circulatory arrest (DHCA) cools the body and creates a bloodless field
- Venous bypass can be used for level II-IV tumors. Venous bypass allows for continuous venous return to the heart while IVC is clamped
- Pringle maneuver (clamping of the hepatic pedicle) can be used to avoid hepatic congestion and IVC bleeding that may occur when IVC is clamped above the hepatic veins (limit exam hepatic ischemia to 20 min)
- Coghill IVC control can be obtained by exposing the infrarenal IVC via pericardiotomy
- Langenbuch maneuver (medial mobilization of level) to expose retrohepatic IVC
- Transperitoneal/extra pericardiacotomy should be used for real time intraoperative monitoring to identify tumor embol
- A multidisciplinary approach, including the involvement of cardiac, vascular, hepatic surgeons as well as a specialized anesthesia team, is highly encouraged for these complex tumors

ADDITIONAL TREATMENT

Radiation Therapy
No role, except for palliation

Additional Therapies
- IVTT can be used to prevent pulmonary embolus; however its use is controversial
- IVTT may become incorporated into IVC filter causing a surgical challenge
- When IVC is thrombosed completely, simple ligation of IVC below hepatic veins may be performed
- Preoperative renal artery embolization
- Avoid for early venous clamping when renal artery control may be difficult; may cause pain and complications (periphlebitic syndrome)
- Can be used as a palliative procedure

COMPLEMENTARY & ALTERNATIVE Therapies
None

ONGOING CARE

PROGNOSIS
- Prognostic factors include TNM stage, nuclear grade, presence of necrosis, histologic type (except for unclassified RCC and collecting duct carcinoma), anatomic features, invasion into adjacent structures (renal sinus, perinephric fat, hepatic veins, collecting system, CV outlet), ECOS performance status, presence of lymph nodes, and distant metastases
- Prognostic significance of tumor thrombus level remains controversial
- Median survival for metastatic disease: 38–116 mo; 5-yr disease specific survival is 4–30%. Patients that present with metastatic disease 5-yr survival 0–10%

COMPLICATIONS
- Overall complication rate is 12.5%, however, the complication rates vary greatly with level of tumor thrombus
- Perioperative death varies from 0.8–10%. There has been a reported rate of mortality up to 40% for level IV IIT
- Most common complications are hemorrhage, pulmonary embolism, wound infection, acute renal failure, ileus, and need for additional surgery.
- The incidence of intraoperative tumor thrombus embolization is 1.5% and is associated with 75% mortality rate.
- Cardiopulmonary bypass is a risk factor for stroke (8% of cases) during nephrectomy for RCC with IIT

FOLLOW-UP

Patient Monitoring
- Surveillance based on TNM staging
- Surveillance labs include metabolic panel, liver function tests
- Surveillance imaging includes abdominal and thoracic imaging

ADDITIONAL READING

None

REFERENCES

RENAI CELL CARCINOMA WITH TUMOR THROMBUS
RENAL CELL CARCINOMA, GENERAL

Matthew A. Meissner, MD
Ganesh V. Raj, MD, PhD, FACS

PATHOPHYSIOLOGY
- Clear cell and papillary RCC develop from the proximal convoluted tubules.
- Chromophobe and collecting duct RCC develop from the distal convoluted tubule and collecting duct, respectively.
- VEGF and TNF-α are growth factors involved in development and progression of RCC.
- Local invasion is common, 20% of cases have invasion of the capsula or collecting system, and 10% have a tumor thrombus.
- Bilateral tumors occur 2–4% of the time with sporadic RCC, either at diagnosis or metachronously.

ASSOCIATED CONDITIONS
- For ESRD patients there is a 2–5-fold increase in risk of developing RCC, most commonly papillary subtype.
- Acquired renal cystic disease in conjunction with ESRD has a 1–2% risk of developing RCC.
- Viral-related RCC is associated with renal anaplasia, pancreatic cysts, ceruleal and spinal hemangioblastomas, and neuroendocrine tumors.
- BHD-related RCC is associated with facial fibrofolliculomas in addition to lung cysts and spontaneous pneumothoraces.

GENERAL PREVENTION
- Smoking cessation reduces the relative risk of developing RCC by 20–50%.
- Weight reduction: it is estimated that 40% of the cases of RCC in USA may be linked to obesity.

DIAGNOSIS
- Physical exam: pain, palpable flank mass, and hematuria. This is rarely seen except in advanced disease.
- Paraneoplastic syndromes found in 20% of patients. These include hypercalcemia (due to paraneoplastic phenomena or osteolytic bone involvement), HTN, polyserositis, and Ca125.
- Constitutional symptoms such as fever, weight loss, and anemia are thought to be due to paraneoplastic syndromes.

PHYSICAL EXAM
- Physical exam findings are usually absent, except in cases of advanced disease.
- Deep palpation for upper quadrant masses and ascites for a renal artery thrombus should be included in the abdominal exam.
- For a suspicious nodule with a careful testicular exam as venous outflow obstruction can occur due to a renal vein tumor thrombus. An epididymal mass may be seen in VHL-related disease.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Initial evaluation includes CBC, electrolytes, creatinine, LFTs, and UA.
- Elevated ESR is present in 50% of patients.
- Staufer syndrome found in 14.4% of patients.
- Characterized by abnormal LFTs from a paraneoplastic syndrome and not from liver metastases.
- Also find elevated alkaline phosphatase, PTT, low albumin, elevated bilirubin, or transaminases.
- Hypertension seen in 13% overall, and in 4.9% resulting from paraneoplastic syndromes.
- Anemia may be due to blood loss.

Imaging
- Thin-slice renal CT scan with and without IV contrast is the best test for diagnosing renal masses.
- Any enhancing lesion on CT or MRI is RCC until proven otherwise.
- Enhancement generally defined as >20 HU increase between contrast and noncontrast phases.
- R.E.N.A.L. Nephrometry score may provide a standardized system for radiologic comparison of renal masses (See RENAL Nephrometry in Section II).
- Any renal mass with a negative CT attenuation (<−20 HU) consistent with fat density is an AML.
- Metastatic evaluation may include CT or MRI of the abdomen, chest x-ray for pulmonary lesions, and a bone scan in patients with elevated alkaline phosphatase or bone pain.

Diagnostic Procedures/Surgery
- Biopsy of a renal mass is typically not included in the workup due to high false-negative rate, risk of bleeding, and remote possibility of seeding the biopsy tract.
- Difficult to distinguish between oncocytoma and RCC on biopsy.
- 85–90% of solid renal masses thought to be RCC are confirmed on final pathology.
- Sensitivity and specificity of FNAB biopsy is 80% and 95%, which is not better than imaging alone.
- Biopsy helps differentiate primary renal neoplasms from metastatic or renal lymphoma.
- Biopsy is now considered more frequently in patients being considered candidates for observation vs. surgical extirpation.
- Biopsy is being used for surveillance in small RCC with >90% accuracy with adequate specimens.

Pathologic Findings
- RCCs are adenocarcinomas, arising from renal tubular epithelial cells.
- Clear cell RCC (formerly known as "conventional RCC") 75–80% of RCC.
- Papillary RCC accounts for 10–15%.
- Type 1: Associated with hereditary papillary renal cell carcinoma (HPRCC).
- Type 2: Aggressive, associated with hereditary leiomyomatosis and renal cell carcinoma (HLRCC).
- Chromophobe 3–5% of solid renal masses, associated with a poor prognosis.
- Collecting duct (Bellini) RCC is rare (<1%), but associated with a very poor prognosis. Occurs in younger patients (40-50 years of age).

PREVALENCE
- 65,150 estimated new cases of RCC in USA (39,140 in men and 24,780 in women); 12 new cases per 100,000/yr.
- Male RCC has a 3–4% yearly increase in incidence since the 1970s.
- 12 new cases per 100,000/yr.
- Male, 3:2.
- Estimated 13,860 deaths will occur in 2014 from RCC.
- 65,150 estimated new cases of RCC in USA (39,140 in men and 24,780 in women); 12 new cases per 100,000/yr.
- Male, 3:2.
- Estimated 13,860 deaths will occur in 2014 from RCC.
- 65,150 estimated new cases of RCC in USA (39,140 in men and 24,780 in women); 12 new cases per 100,000/yr.
- Male, 3:2.
- Estimated 13,860 deaths will occur in 2014 from RCC.
- 65,150 estimated new cases of RCC in USA (39,140 in men and 24,780 in women); 12 new cases per 100,000/yr.
SURGERY/OTHER PROCEDURES

**Systemic immunotherapy and targeted molecular therapy**

**GENERAL MEASURES**
- Radiofrequency ablation/cryoablation minimally invasive.
- Radical nephrectomy is the standard of care for solid renal masses.
- Partial nephrectomy is now the standard of care for non-functioning kidneys.
- Surgical extirpation (radical or partial nephrectomy)
  - Wilms tumor (nephroblastoma)
  - Reninoma (JG apparatus tumors)
  - Renal sarcomas
  - Renal lymphoma
  - Renal cell carcinoma
  - Pseudotumors (hypertrophied column of Bertin, or oncocytoma)
  - Metanephric adenoma
  - Inflammatory masses (xanthogranulomatous pyelonephritis)
  - Hemangioma
  - Focal pyelonephritis
  - Cysts (hemorrhagic, infected)
  - Cystic nephromas (multilocular cystic nephroma)
  - Collecting duct tumor (Bellini)
  - Angiomyolipoma (fat poor)
  - Sarcomatoid differentiation: Reported as presence of sarcomatoid features.
  - Renal medullary RCC found in African Americans in later stages.

**TREATMENT**

**GENERAL MEASURES**
- Surgical extirpation (radical or partial nephrectomy)
- Chemotherapy: Limited role.
- Immunotherapy: Limited role.

**MEDICATION**
- Surgical removal is the mainstay of treatment for renal cell carcinoma.
- VHL syndrome is associated with chromosome 3p deletion and RCC, as well as other tumors.

**SPECIAL CONSIDERATIONS**
- Ongoing surveillance is recommended for patients with a history of RCC.
- Surveillance is tailored to tumor stage.

**PROGNOSIS**
- The single most important prognostic factor for RCC is pathologic stage (T):
  - pT1a: 90–100% 5-yr survival
  - pT1b: 70–80% 5-yr survival
  - pT2: 50–60% 5-yr survival
- Node-positive RCC: 0–20% 5-yr survival

**ADDITIONAL TREATMENT**
- Radiation Therapy
  - Radiation is limited to palliation of systemic metastases; no role in the management of clinically localized RCC.
- Additional Therapies
  - Resection of solitary metastatic lesions (≤1 lung) may be useful in selected cases.
- No role for adjuvant systemic therapy in localized RCC.

**ONGOING CARE**
- Surveillance is recommended for patients with a history of RCC.
- Surveillance is tailored to tumor stage.

**REFERENCES**

  - Renal Cell Carcinoma, General Image
  - Renal Cell Carcinoma, Localized (T1–T2)
  - Renal Cell Carcinoma, Locally Advanced (T3–T4)
  - Renal Cell Carcinoma, Metastatic (M1–M+)
  - Renal Cell Carcinoma, Pediatric
  - Renal Mass
  - Reference Tables: TMM: Kidney Cancer
  - Von Hippel-Lindau Disease/Syndrome

**ICD-10**
- T82.0 Malignant neoplasm of kidney, except pelvis
- N99.70 Hematuria, unspecified
- T98.0 Abdominal pain, other specified site

**ICD10**
- C61.9 Malignant neoplasm of urine, except pelvis
- B10.9 Unspecified abdominal pain

**CLINICAL/SURGICAL PEARLS**
- Most common solid renal mass is clear cell RCC.
- Most renal masses are detected incidentally.
- Von Hippel-Lindau syndrome is associated with chromosome 3p deletion and RCC, as well as other tumors.
- Surgical removal is the mainstay of treatment for RCC.
- Partial nephrectomy is increasingly utilized for larger, clinically localized tumors.
PATHOPHYSIOLOGY

Renal cell carcinoma (RCC) refers to an abnormally growing cell that arises from the renal proximal tubule. RCCs are rare, but they are the most common malignancy of the kidney. The prognosis for RCC depends on several factors, including the stage of the disease, the grade of the tumor, and the presence of metastatic disease.

RCCs are derived from the proximal convoluted tubule of the kidney. They can arise from the renal cortex or the renal medulla. The majority of RCCs are found in the cortical region, while a small proportion are found in the medullary region. RCCs are often characterized by their rapid growth and ability to metastasize to other organs, particularly the lungs.

The pathophysiology of RCC involves several key processes, including angiogenesis, tumor cell proliferation, and evasion of immune surveillance. RCCs are known to produce angiogenic factors, such as vascular endothelial growth factor (VEGF), which promote the growth of new blood vessels in the tumor. This process is crucial for tumor growth and metastasis.

RCCs are also known to evade immune surveillance by downregulating the expression of MHC class I molecules, which are essential for the recognition of tumor cells by the immune system. This allows RCCs to escape immune surveillance and continue to grow and spread.

The histology of RCCs is variable, and the specific histologic subtype can impact the treatment options and prognosis. RCCs can be classified into several subtypes, including clear cell RCC, papillary RCC, chromophobe RCC, and collecting duct RCC.

DIAGNOSIS

The diagnosis of RCC is typically made through imaging studies, such as computed tomography (CT) or magnetic resonance imaging (MRI). These studies can help to identify the location, size, and extent of the tumor. Blood tests, such as laboratory tests, can also be used to assess the tumor burden and to monitor the response to therapy.

TREATMENT

The treatment of RCC depends on the stage and subtype of the tumor. General options include surgery, targeted therapy, immunotherapy, and radiation therapy. The choice of treatment depends on several factors, including the tumor stage, the patient's overall health, and the potential side effects of the treatment.

In the case of localized RCC (T1-T2), the treatment options include surgery, such as nephrectomy or partial nephrectomy, which involves the removal of the affected kidney. Targeted therapy, such as sunitinib or axitinib, can also be used to inhibit the growth of the tumor. Immunotherapy, such as pembrolizumab, can be used to stimulate the patient's immune system to fight the tumor.

In the case of metastatic RCC (T3-T4), the treatment options include systemic therapy, such as targeted therapy or immunotherapy. Targeted therapy, such as everolimus or axitinib, can be used to inhibit the growth of the tumor. Immunotherapy, such as nivolumab or pembrolizumab, can be used to stimulate the patient's immune system to fight the tumor.

In the case of advanced RCC, the treatment options include systemic therapy, such as targeted therapy or immunotherapy. Targeted therapy, such as sunitinib or axitinib, can be used to inhibit the growth of the tumor. Immunotherapy, such as nivolumab or pembrolizumab, can be used to stimulate the patient's immune system to fight the tumor.
Therapies Complementary & Alternative

**Additional Therapies**

**Radiation Therapy**

N/A

**First Line**

**MEDICATION**

- No role in localized RCC outside of clinical trials of focal radiotherapy (Cyberknife) or HIFU
- Used for painful/ bulk metastases and CNS metastasis in advanced RCC

**Additional Therapies**

- Complementary & Alternative Therapies

**Ongoing Care**

**PROGNOSIS**

- Local recurrence after resection is ~2–3% after radical nephrectomy and 4–6% after partial depending on pathology
- 5-y risks of recurrence for local or regional RCC fully excised are approximately:
  - ≤5–9% low-risk disease
  - 20–25% intermediate-risk disease
  - ≥60–80% high-risk disease
- Progression for partial nephrectomy with a positive margin is less clear. Related to pathology and biology. Every attempt should be made intraoperatively to avoid a positive surgical margin; with focal positive margin, close observation is often indicated.

**COMPLICATIONS**

- Acute surgical/medical risks depend on treatments, techniques, comorbidities, and complexity of the mass. Overall perioperative death rate ~0.5%. Risk of major Clavien grade 3–5 complications: 6.4%, 11.1%, 21.9% for low-, intermediate-, and high-complexity lesions (4).
- Risks after partial nephrectomy: Urinary leak/ fistula, AIF, bleeding, transient or permanent decline in renal function (5)
- Increased risk of Hypertensive systemic disorder (Hypertension) with gadolinium (eGFR < 30 mL/min per 1.73 m²) and/or risk of contrast-induced nephropathy following use of iodinated contrast for radiographic surveillance

**Follow-up**

- Patient Monitoring
  - Periodic history, physical (including BP monitoring), and selected lab studies (urine analysis) at least yearly
  - Radiographic staging/treatment-specific surveillance mandatory based on clinical stage and mode of treatment. Surveillance may be adjusted for other risk factors (papillary histology).
- Following ablation, initial radiologic follow-up requires lack of enhancement on postcontrast-based CT or MR (≤3–6 mo after procedure). Biopsy confirmation of successful ablation is recommended. Occasionally after stygomy, an area of rim enhancement can be seen that should resolve within 1 to 3 mo.
- NCCN (National Comprehensive Cancer Network) guidelines (level of evidence; based on scientific evidence, practice recommendations)
  - Every 6 mo for 2 yr, then annually for 5 yr. History, physical, metabolic panel
  - At 2 yr (based on recurrence risk) chest and abdominal pelvic imaging then risk-based

**CODES**

- 189.0 Malignant neoplasm of kidney, except pelvis
- ICD10
  - C64.1 Malignant neoplasm of right kidney, except pelvis
  - C66.2 Malignant neoplasm of left kidney, except renal pelvis
  - C64.9 Malignant neoplasm of upper kidney, except renal pelvis

**CLINICAL/SURGICAL PEARLS**

- Always review the images and carefully assess the presence of the contralateral kidney and the adrenal glands.
- Do not overtreat or undertreat renal mass.

**403**
**GENETICS**

- **Tuberous Sclerosis (TSC)**
  - Two tumor-gene loci (TSC1, TSC2) on chromosomes 9q34 and 16p13.
  - Mutations in TSC1 or TSC2 predispose to RCC.
- **Birt–Hogg–Dubé Syndrome (BHD)**
  - Mutations in the TSC2 gene.
- **Familial Renal Cell Carcinoma (FIRCC)**
  - Mutations in the VHL gene.
- **Familial Renal Parenchymal Tumors (FRPT)**
  - Mutations in the CDKN2A gene.
- **Familial Hypophosphatemic Rickets (FHR)**
  - Mutations in the PHEX gene.

**RISK FACTORS**

- **Increased Age**
  - RCC incidence increases with age.
- **Increased Obesity**
  - RCC incidence is higher in individuals with obesity.
- **Increased Alcohol Consumption**
  - RCC incidence is higher in individuals who consume alcohol.
- **Increased Smoking**
  - RCC incidence is higher in individuals who smoke.
- **Increased Parity**
  - RCC incidence is higher in individuals with high parity.
- **Increased Menopausal Status**
  - RCC incidence is higher in individuals who are menopausal.
- **Increased Family History**
  - RCC incidence is higher in individuals with a family history of RCC.
- **Increased History of Varicocele**
  - RCC incidence is higher in individuals with a history of varicocele.
- **Increased History of Pulmonary Embolism**
  - RCC incidence is higher in individuals with a history of pulmonary embolism.

**PATOPHYSIOLOGY**

- **Increased Incidence**
  - RCC incidence increases with age.
- **Increased Obesity**
  - RCC incidence is higher in individuals with obesity.
- **Increased Alcohol Consumption**
  - RCC incidence is higher in individuals who consume alcohol.
- **Increased Smoking**
  - RCC incidence is higher in individuals who smoke.
- **Increased Parity**
  - RCC incidence is higher in individuals with high parity.
- **Increased Menopausal Status**
  - RCC incidence is higher in individuals who are menopausal.
- **Increased Family History**
  - RCC incidence is higher in individuals with a family history of RCC.
- **Increased History of Varicocele**
  - RCC incidence is higher in individuals with a history of varicocele.
- **Increased History of Pulmonary Embolism**
  - RCC incidence is higher in individuals with a history of pulmonary embolism.

**DIAGNOSIS**

- **Imaging**
  - **CT Scan**
    - Evaluated for pulmonary metastasis.
  - **MRI**
    - Noncontrast MRI with and without injection of gadolinium to evaluate for renal lesions.
  - **Transabdominal US**
    - Can be used to detect RCC.
  - **Transesophageal Echocardiography (TEE)**
    - Can be used to detect metastases to the heart.
  - **LFTs**
    - Can be used to detect metastases to the liver.
  - **Chest X-ray**
    - Can be used to detect metastases to the lungs.
  - **Bone Scan**
    - Can be used to detect metastases to the bone.
  - **PET Scan**
    - Can be used to detect metastases to distant organs.

**PHYSICAL EXAM**

- **Palpable Abdominal Mass**
  - RCC can present as a palpable abdominal mass.
- **Bilateral Abdominal Tenderness**
  - RCC can present with bilateral abdominal tenderness.
- **Lower Extremity Edema**
  - RCC can present with lower extremity edema.
- **Isolated Right-Sided Varicocele**
  - RCC can present with an isolated right-sided varicocele.

**DIAGNOSTIC TESTS & INTERPRETATION**

- **CT Scan**
  - Can be used to detect both local and distant metastases.
  - Can be used to detect both local and distant metastases.
  - Can be used to detect both local and distant metastases.
  - Can be used to detect both local and distant metastases.
  - Can be used to detect both local and distant metastases.
  - Can be used to detect both local and distant metastases.

**PROGNOSIS**

- **Stage I**
  - RCC that is confined to the kidney.
  - 5-year survival rate is up to 90%.
- **Stage II**
  - RCC that has invaded the renal vein or the inferior vena cava.
  - 5-year survival rate is up to 65%.
- **Stage III**
  - RCC that has invaded the renal vein or the inferior vena cava.
  - 5-year survival rate is up to 30%.
- **Stage IV**
  - RCC that has spread to distant sites.
  - 5-year survival rate is up to 15%.

**TREATMENT**

- **Surgical Resection**
  - RCC can be treated with surgical resection.
  - RCC can be treated with surgical resection.
  - RCC can be treated with surgical resection.
  - RCC can be treated with surgical resection.
  - RCC can be treated with surgical resection.

**PROGNOSIS**

- **Stage I**
  - RCC that is confined to the kidney.
  - 5-year survival rate is up to 90%.
- **Stage II**
  - RCC that has invaded the renal vein or the inferior vena cava.
  - 5-year survival rate is up to 65%.
- **Stage III**
  - RCC that has invaded the renal vein or the inferior vena cava.
  - 5-year survival rate is up to 30%.
- **Stage IV**
  - RCC that has spread to distant sites.
  - 5-year survival rate is up to 15%.
TREATMENT

GENERAL MEASURES
- Pro re nata arterioles embolization may cause the tumor hemorrhage to regress and reduce the mortality of surgery as a result.
- Avoid IVC filter placement.

MEDICATION
The role of neoadjuvant targeted therapies (eg, sunitinib, sorafenib, others) for downsizing the primary tumor and the IVC thrombus is controversial: 5–10%.

SURGERY/OTHER PROCEDURES
- Radical nephrectomy is standard of care.
- Neoplastic surgery is possible in selected patients with locally advanced RCC, with equivalent oncologic efficacy to radical nephrectomy (2).
- 45–70% of T3b patients can be cured with nephrectomy for clear cell renal cell carcinoma.

ADDITIONAL TREATMENT
Radiation Therapy
- Role is limited; no survival benefit to preoperative treatment
- May slow growth if residual tumor left after surgery; rarely used
- May palliate symptomatic local recurrences in nonsurgical candidates

ADDITIONAL THERAPIES
- Targeted agents to growth factors are being evaluated in both an adjuvant and neoadjuvant setting for patients at high risk for recurrence (4).

COMPLEMENTARY & ALTERNATIVE THERAPIES
None proven

ONGOING CARE

PROGNOSIS
- T3a: 60–80% 5-yr survival
- T3b: 40–60% 5-yr survival
- T4: 0–20% 5-yr survival
- Node-positive RCC has 0–20% 5-yr survival
- For T4 tumors, the median time to recurrence is only 5–9 mo

COMPLICATIONS
- Surgical complications are bleeding, infection, injury to surrounding organs (live, spleen, bowel, pancreas). Urine leak in partial nephrectomy.
- Pulmonary embolism from tumor thrombus
- Advanced tumors can bleed spontaneously without causing flank pain or into the urine resulting in hematuria and/or fistula formation.
- Venous congestion resulting in bilateral lower-extremity edema, varicoceles, or portal HTN from tumor thrombus into the renal, caval, or hepatic venous system.

FOLLOW-UP

Patient Monitoring
- T3: Every 6 mo for 3 yr then annually for 5 yr. H+, P, comprehensive metabolic panel, LDH, chest and abdomen imaging at 2–6 mo then as indicated:
- T4: Every 3 mo history and physical exam, CTR, labs, every 6 mo abdominal CT for 3 yr

Patient Resources
- Kidney Cancer Association (www.kidneycancer.org)
- National Cancer Institute, Kidney Cancer (www.cancer.gov/cancertopics/types/kidney)

REFERENCES

ADDITIONAL TREATMENT
- Reduction in primary site.
- Additional therapies (eg, sunitinib, sorafenib, others) for downsizing the primary tumor and the IVC thrombus is controversial: 5–10%.
- Medullary carcinoma associated with sickle cell trait in young African Americans, is often advanced and metastatic at the time of diagnosis; death occurs within a few months of diagnosis.
- Sarcomatoid variants of all subtypes have been described and are associated with a worse prognosis.

DIFFERENTIAL DIAGNOSIS
- Hemangioma
- Wilms tumor (nephroblastoma)
- Urothelial carcinoma
- Oncocytoma
- Metastasis from other primary tumor
- Leiomoma
- Renal lymphoma
- Urachal carcinoma
- Wilms tumor (nephroblastoma)

PROGNOSIS
- Death usually occurs within a few months of diagnosis.
- Few patients with metastatic disease at presentation survive for more than 1 yr.
- None proven

CODES
- ICD9: 198.0 Malignant neoplasm of kidney, except pelvis
- C64.1 Malignant neoplasm of right kidney, except pelvis
- C64.9 Malignant neoplasm of unsp kidney, except pelvis
- C19.89 Secondary malignant neoplasm of other specified sites

ICD10
- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C19.89 Secondary malignant neoplasm of other specified sites

CLINICAL/SURGICAL PEARLS
- Detailed evaluation of extent of the disease is critical.
- Consult vascular and/or cardiovascular surgeon if needed.
RENTAL CELL CARCINOMA, METASTATIC (N+, M+)

Jiang Ling, MD
Wm. Kevin Kelly, DO

DIAGNOSIS

HISTORY
Usually no symptoms in early stage but incidental diagnosis of kidney mass. Metastasis may or may not cause symptoms.

Gross hematuria
Flank or abdominal pain
Symptoms related to involved organ(s)

Constitutional symptoms:
– Fatigue, weight loss, fever, or lower-extremity edema

PHYSICAL EXAM
With attention to abdominal mass, adenopathy, lower-extremity edema

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM

IMAGING

- MRI or CT of abdomen and pelvis (7th edition):
  • N1: Metastasis in regional lymph node(s)
  • N2: Metastasis via lymphatics
  • M1: Metastasis

LAB

- Complete metabolic panel
- CBC: Anemia of chronic disease in up to 30%
- Urinalysis: Hematuria
- Serum electrolytes
- Creatinine
- Ferritin
- Fibrinogen

DIFFERENTIAL DIAGNOSIS

- Renal masses:
  • Angiomyolipoma (fat-poor)
  • Collecting duct tumors
  • Cystic nephroma
  • Cysts (hemorrhagic, infected)
  • Focal/segmental glomerulosclerosis
  • Hemangioma
  • Inflammatory masses (xanthogranulomatous pylephlebitis, abscess)
  • Lymphoma
  • Metanephric adenoma
  • Metastasis from other primary tumor
  • Osteosarcoma
  • Pancreatic adenocarcinoma
  • RCC
  • Renal lymphoma
  • Renal medullary carcinoma
  • Sarcomas
  • Reninoma (phaeochromocytoma tumors)

- Urothelial carcinoma
- Wilms tumor (neuroblastoma)
- Lymphangiomyomatosis
- Inflammatory related to RCC
- RCC
- Infections/Inflammatory:
  • Granulomatous: TB, sarcoidosis, histoplasmosis, lymphangitis, Castleman disease, etc.
  • Non-Nongranulomatous: Viral, bacterial (if abscess in local area), sinus histiocytosis
  • Primary lymphatic malignancy: Lymphoma (non-Hodgkin and Hodgkin, others)
- Other metastatic malignancies:
  • Gastrinoma (Duodenal)
  • Carcinoid tumor, carcinoid syndrome, neuroendocrine tumors
  • Sarcomas
  • Renal medullary carcinoma
  • RCC
  • Oncocytoma
  • Metanephric adenoma
  • Inflammatory masses (xanthogranulomatous pyelonephritis, abscess, etc.)

GENERAL MEASURES

- Stage IV disease may also benefit from systemic therapy
- Minimal regional adenopathy does not preclude surgery
- Potential candidate for nephrectomy and/or surgical metastasectomy
- Reconstructive primary RCC and a solitary resectable metastasis
- A solitary recurrence after prolonged disease-free interval from nephrectomy
- Tends to be resistant to both traditional chemotherapy and radiation therapy

GENERAL PREVENTION

- Smoking cessation helps prevent primary tumor
Cytoreductive nephrectomy in patients with metastatic renal cancer is the mainstay of treatment; improve survival for M1
- Multifocal renal metastases (T1a) or mTOR inhibitors
- mTOR inhibitors or mTOR inhibitors
- Data for non-clear cell RCC therapy limited
- Combination therapies are being explored.

Cytoreductive surgery should be considered for M1 disease.

Other immunotherapy is under development

**mA**
- Strongly consider metastasectomy for amendable and isolated solitary metastasis (synchronous or metachronous).
- Metastasectomy should be performed in radiographically suspicious cases; however, ultimate role and benefit is yet to be defined.

**ADDITIONAL TREATMENT**

**Radiation Therapy**

- Palliative role for osseous or CNS metastasis or pain control

**Additional Therapies**

- Many other agents under study and reported:
  - Non-gonadorelin agonistic: hemostatic cell transplantation
  - Interferon-γ, vaccines, other interleukins alone and in combination
  - Multiple studies under way addressing sequencing and combination of targeted therapies along with immunotherapy

**Complementary & Alternative Therapies**

- N/A

**ONGOING CARE**

**PROGNOSIS**

- 5 yr survival: Improving (7)
  - Stage I: 85–95%
  - Stage II: 50–70%
  - Improved survival with the following characteristics: Long interval between nephrectomy and the appearance of distant metastases, a single metastatic site, and the absence of intrarenal adenopathy

**COMPLICATIONS**

- Related to treatment:
  - High-dose IL-2: Vascular leak syndrome
  - TKIs: Fatigue, HTN, hand and foot syndrome, GI toxicity, hypothyroidism
  - mTOR inhibitors: fatigue, rash, hyperglycemia, dyslipidemia
  - Others related to disease progression

**FOLLOW-UP**

- Patient Monitoring:
  - Depends on stage of disease and treatment
  - Usually chest and abdominal imaging every 3–6 mo if not being treated
  - Imaging every 3–4 cycles if underactive systemic treatment
  - Serum chemistries and liver function tests as routine
  - Usually chest and abdominal imaging every 3–6 mo if not being treated
  - Imaging every 3–4 cycles if underactive systemic treatment
  - Serum chemistries and liver function tests as routine

**Patient Resources**

- National Cancer Institute
- American Society of Clinical Oncology
- American Society for Radiation Oncology

**REFERENCES**

**ADDITIONAL READING**

- NCCN Guidelines. Available at:https://www.nccn.org/prof/clinical.asp (Accessed August 20, 2014)

**CODES**

- ICD-10
  - C61.0 Malignant neoplasm of kidney, except pelvis
  - C61.2 Secondary and unspecified malignant neoplasm of intra-abdominal lymph nodes

**ICD-O**

- C104.0 Malignant neoplasm of kidney, except pelvis
- C61.2 Secondary and unspecified malignant neoplasm of intra-abdominal lymph nodes

**CLINICAL/SURGICAL PEARLS**

- Cytoreductive surgery should be considered for M1 disease.
- Only high-dose IL-2 provide durable complete response (CR).
- No targeted agents show significant complete response (CR).
- Patients achieving response with targeted agents such as TKI have a response duration of <8–10 mo (medium: ~12 mo) with continuous therapy treatment.
- Combination therapies are being explored.
RENAL CELL CARCINOMA, PEDIATRIC
Sarah M. Lambert, MD
Pasquale Casale, MD, FACS

BASICS
DESCRIPTION
Renal cell carcinoma (RCC) is a very rare tumor in childhood arising from the renal tubular epithelium.

EPIDEMIOLOGY
Incidence
• 2–4% of all pediatric renal tumors
• Only ~4 cases of pediatric RCC per year
• Estimated at <0.3% of all pediatric tumors
• Just over 350 cases reported in the literature
• Mean age of presentation between 8 and 10 yr vs. <3 yr for Wilms tumor
• Equal male:female

RISK FACTORS
• Von Hippel-Lindau syndrome
• Tuberous sclerosis

PATHOPHYSIOLOGY
• Thought to arise from renal tubular epithelium
• Most frequently papillary subtype with Xp11 translocation
• Lung and bone are the most common distant metastases

ASSOCIATED CONDITIONS
• Tubular sclerosis, chronic renal failure, nephrolithiasis, and tumor with chemotherapy
• Rarely associated with adult familial RCC

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
• Gross hematuria (~40%), flank pain, abdominal distension (2)
• Nausea, vomiting, malaise common
• Pain in up to 50%
• 30% found incidentally (2)

PHYSICAL EXAM
• Palpable abdominal mass (~40%) (2)
• Triad of hematuria, flank pain, and palpable mass found in ~6% of children (3)

DIAGNOSTIC TESTS & INTERPRETATION

Lab
• CBC: Polycythemia is rare
• Urinalysis: Hematuria found in ~40% of patients (3)
• Liver and renal function tests: Baseline prior to treatment

Imaging
• Abdominal x-ray may show tumor calcifications (~25%) vs. Wilms tumor (~5%) (3)
• US demonstrates solid or cystic renal mass
• CT or MRI with and without contrast reveal enhancing renal mass.
• Pediatric RCCs typically present as large, heterogeneous masses, commonly hemorhage and contain internal calcifications.
• IVP can demonstrate renal mass by displacement of the collecting system.
• Chest x-ray or chest CT scan for workup of metastatic disease.
• Radionuclide bone scan is indicated based on concern for mets.

Diagnostic Procedures/Surgery
• Biopsy is not indicated

Pathologic Findings
• Predominantly papillary histologic features in children vs. clear cell features in adults
• Pathologic staging based on modified Robson staging system
• Up to 25% pediatric RCC cannot be clearly classified due to atypical features
• Pathologic parameters typically associated with poor outcome in adults (metastasis/high tumor stage, high Fuhrman nuclear grade, angiolymphatic invasion, tumor necrosis), do not appear to have similar implications in pediatric patients

DIFFERENTIAL DIAGNOSIS
• Benign renal masses in children:
  – Choledochal cyst, intestinal duplication cyst
  – Congenital mesoblastic nephroma
  – Hydronephrosis
  – Mesoblastic cyst
  – Multilocular cystic renal tumor
  – Papillary kidney
  – Rhabdoid tumor
• Malignant renal masses in children:
  – Neuroblastoma
  – Lymphoma
  – Neuroblastoma
  – RCC
  – Rhabdomyosarcoma
  – Wilms tumor

TREATMENT

GENERAL MEASURES
Management is primarily surgical excision by either radical nephrectomy or partial nephrectomy.

MEDICATION
First Line
• The use of chemotherapy, immunotherapy, or tyrosine kinase inhibitors is not adequately described in pediatric population.
• The use of tyrosine kinase inhibitors should be considered in the pediatric patient with unresectable, metastatic, or advanced-stage RCC.
• Small series of patients treated with neoadjuvant chemotherapy according to Wilms tumor protocol.

Second Line
Surgery/Other Procedures
• Radical nephrectomy (4)
  – Removal of entire kidney and portion of the ureter
• Common approaches in children include flank and abdominal incisions
  – Wilms tumor
  – RCC
• Laparoscopic and robotic assisted radical or partial nephrectomy for RCC in children are described in select cases (6,7)

SURGICAL PROCEDURES
• Radical nephrectomy (4)
  – Removal of entire kidney and portion of the ureter
  – Common approaches in children include flank and abdominal incisions
• Partial nephrectomy (5)

408
ADDITIONAL TREATMENT

Radiation Therapy
Has been used for both initial treatment and recurrence but not well studied in pediatric populations.

Additional Therapies
- Adjuvant chemotherapy for metastatic disease has been tried in the pediatric population but not well characterized.
- Tensiop inhibitors have been used in children with metastatic disease but data are limited (9).

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Overall survival similar to adult RCC and depends on (Robson) stage:
  - Stage I (100%) and II (80%)
  - Stage III (75%), stage IV (15%) (2)

COMPLICATIONS
- Surgical complications (bleeding, infection, diaphragmatic bowel injury)
- Metastasis to lung and bone, multiple other sites

FOLLOW-UP

Patient Monitoring
- Adult protocols followed as there are no pediatric protocols.
- No long-term follow-up guidelines:
  - Physical exam, chest x-ray, chemistry panel, CBC, and urinalysis every 6 mo for 5 yr.
  - CT on yearly basis for 5 yr.
- Risk of chronic kidney disease likely attributed to reduced renal reserve capacity should be recognized and treated with nephrologic evaluation (8).

CODES

ICD9
- 189.0 Malignant neoplasm of kidney, except parotid
- 197.0 Secondary malignant neoplasm of lung
- 198.3 Secondary malignant neoplasm of bone and bone marrow

ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C78.00 Secondary malignant neoplasm of unspecified lung
- C79.51 Secondary malignant neoplasm of unspecified bone

CLINICAL/SURGICAL PEARLS
The most common subtypes of RCC in children are the translocation-associated tumors, papillary RCC, renal medullary carcinomas, and oncocytic RCC.
RENAL COLIC

Scott G. Hubosky, MD

ASSOCIATED CONDITIONS
- Any process causing obstruction of the upper urinary tract
  - Ureteral stone
  - Ureteral stricture
  - Upper tract urethral neoplasm
  - Extrinsic urinary obstruction
  - Intrarenal urinary injury
- Urinary tract infection
  - Pyelonephritis
  - Renal abscess
- Recent urologic surgery
  - Obstructing blood clots from upper tract
  - Ureteral kink in poor position
  - Presence of poorly draining percutaneous nephrostomy tube
- Residual ureteral stone fragments after lithotripsy
- Miscellaneous
  - Renal artery embolus/infarction
  - Renal vein thrombosis

GENERAL PREVENTION
- Empiric advice for nephrolithiasis prevention
  - Adequate hydration
  - Enough fluid consumption to generate 2.5 L of urine output per day
  - Low-sodium diet
  - Daily sodium intake should be <2,500 mg
  - Diet rich in sodium result in hypercalciuria
  - About 82% of renal stones produced have calcium as a constituent
  - Normal calcium diet
  - Calcium intake should range between 800 and 1,200 mg/day
  - Vitamin D, supplements, and antacids should be considered

PHYSICAL EXAM
- General appearance is that of a restless patient unable to be still
- Usually unilateral flank pain with radiation to ipsilateral lower quadrant

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Serum creatinine/BUN and electrolytes
- Complete blood count
- Urinalysis
- Look for signs of blood or infection
- Urine culture

IMAGING
- CT scan of abdomen and pelvis without any contrast
  - Most sensitive way to detect urinary tract calculi (99% sensitivity to detect ureteral stones)
  - Relatively expensive and subjects patients to radiation exposure
  - Low-dose radiation dose protocol still gives 95% sensitivity for ureteral stone detection with 60% less radiation exposure
- CT urogram
- CT scan of abdomen/pelvis with IV contrast which is useful to expand diagnostic capability when no ureteral stones are found
- Can diagnose causes of colic not caused by stones such as UPJ obstructions or intraluminal filling defects such as neoplasms, fungus balls, or blood clots
- Renal/bladder ultrasound
  - No radiation exposureSafe in pregnancy and in pediatric patients
- Ask for double-void assessment of ureteral jets
- Presence of ureteral jets rules out complete ureteral obstruction (although partial obstruction may exist)
- Presence of ureteral jet may indicate obstruction of the renal pelvis
  - Relies on indirect evidence to diagnosis obstruction
  - May detect calicification along the expected course of the ureter
  - Not very sensitive for detecting small ureteral stones
- IVU or urogram
  - May detect calicification along the expected course of the ureter
- Not very sensitive or specific
- Benefits are low-radiation dose and is inexpensive

Diagnostic Procedure/Surgery
- Relief of obstruction may be necessary
  - Unilateral stent placement
  - Percutaneous nephrostomy
- Culture-specific antibiotics
  - If infection is present

Pathologic Findings
N/A

BASICS

DESCRIPTION
- Renal colic is a constellation of symptoms that usually accompanies upper urinary tract obstruction (UCO).
- Pain involving the flank and/or groin, with radiation to the ipsilateral scrotum or labia majora.
- Pain character is colicky with patients demonstrating a restless nature, unable to stay still.
- Pain is abrupt in onset and not associated with physical activity or positions.
- Nausea/vomiting
  - Simultaneously presents with flank pain but not in all cases
- Irritative or obstructive voiding complaints which are not present at baseline
- Urinary frequency, feeling of incomplete emptying, or hesitancy
- Hematuria
- Gross or microscopic
- Presence of hematuria strongly suggests underlying urologic etiology over gastrointestinal origin

EPIDEMIOLOGY

Incidence
- Renal colic accounts for about 1% of all emergency department visits (2,3,4) representing over 1 million cases per year.

Prevalence
- Renal colic caused by nephrolithiasis has an estimated prevalence of 6.5% in men and 4.1% in women over a study period of 1988–1994 (4,5).
- Presence or absence of ureteral jets
  - Presence of ureteral jets rules out complete ureteral obstruction (although partial obstruction may exist)
- Presence of ureteral jet may indicate obstruction of the renal pelvis
  - Relies on indirect evidence to diagnosis obstruction
  - May detect calicification along the expected course of the ureter
  - Not very sensitive for detecting small ureteral stones
- IVU or urogram
  - May detect calicification along the expected course of the ureter
  - Not very sensitive or specific
  - Benefits are low-radiation dose and is inexpensive

DIAGNOSTIC PROCEDURE/SURGERY
- Relief of obstruction may be necessary
  - Unilateral stent placement
  - Percutaneous nephrostomy
- Culture-specific antibiotics
  - If infection is present

BASICS

DESCRIPTION
- Renal colic is a constellation of symptoms that usually accompanies upper urinary tract obstruction (UCO).
- Pain:
  - Involves the flank and/or groin, with radiation to the ipsilateral scrotum or labia majora
  - Pain character is colicky with patients demonstrating a restless nature, unable to stay still
- Pain is abrupt in onset and not associated with physical activity or positions.
  - Nausea/vomiting
  - Simultaneously presents with flank pain but not in all cases.
- Irritative or obstructive voiding complaints which are not present at baseline
- Urinary frequency, feeling of incomplete emptying, or hesitancy
- Hematuria
  - Gross or microscopic
  - Presence of hematuria strongly suggests underlying urologic etiology over gastrointestinal origin

EPIDEMIOLOGY

Incidence
- Renal colic accounts for about 1% of all emergency department visits (2,3,4) representing over 1 million cases per year.

Prevalence
- Renal colic caused by nephrolithiasis has an estimated prevalence of 6.5% in men and 4.1% in women over a study period of 1988–1994 (4,5).

Risk Factors
- History of nephrolithiasis
- Recent urologic surgery
- History of ureteral stricture
- Pelvic radiation history

Genetics
N/A

Pathophysiology
- Presence of obstruction anywhere along the course of the ureter results in stretching of involuntary smooth muscle lining the ureter and renal pelvis.
- This stretching of the ureteral smooth muscle is exacerbated by baseline ureteral peristalsis.
- Stretching of hollow viscera, such as the ureter renal pelvis, is a well-known stimulus for pain as triated by the autonomic nervous system (TAN).
- The kidneys, proximal ureters, and stomach are all served by the colic plexus thus explaining why nausea and vomiting frequently accompany renal colic.

Diagnosis

History
- Sudden onset of colicky flank pain
  - May be associated with simultaneous nausea or vomiting
  - May have associated gross or microscopic
  - May have radiation to ipsilateral or scrotum/labia majora
- Pain is colicky and intermittent
- The location and characteristics of renal colic pain relating to urolithiasis (6):
  - Stones obstructing UPJ: Mild to severe deep flank pain relieved by fluid intake or voiding
  - Stones obstructing ureter: Abrupt, severe, colicky pain in the flank and/or ipsilateral lower abdomen
    - Radiation to testicles or labia
    - Intense nausea with or without vomiting
  - Ureteral stone: Radiate to flank or lumbar area
    - Intermittent: Radiate anteriorly and caudally
    - Distal ureteral stones: Radiate into groin or perineum
    - Midureteral calculi: Radiate anteriorly and caudally
  - Stones obstructing UPJ: Mild to severe deep flank pain relieved by fluid intake or voiding
  - Stones obstructing ureter: Abrupt, severe, colicky pain in the flank and/or ipsilateral lower abdomen
  - Radiation to testicles or labia
  - Intense nausea with or without vomiting

Diagnostic Procedures/Surgery

- Relief of obstruction may be necessary
  - Unilateral stent placement
  - Percutaneous nephrostomy
- Culture-specific antibiotics
  - If infection is present

Pathologic Findings
N/A
Differential Diagnosis
- Ureteral calculus
- Unilateral obstruction
- UPI obstruction
- Upper tract urothelial neoplasm
  - Upper tract urothelial carcinoma
  - Transitional cell papilloma
- Iatrogenic ureteral obstruction
  - Urinary leakage after nephrectomy or colon resection
  - Obstructing residual stone fragment after lithotripsy
  - Obstructing blood clots following upper tract urothelial resection procedure
- Upper urinary tract infection
  - Pyelonephritis
  - Pyonephrosis
  - Renal abscess
  - Obstructing fretty ball
- Renal vascular etiology
  - Renal artery embolic/luminal obstruction
  - Renal vein thrombosis

Treatment

General Measures
- Rule out sepsis
- Treat infection
- Control pain
- Alleviate obstruction, if present
- Treat infection, if present
- Rule out sepsis
- Treat infection
- Alleviate obstruction, if present
- Control pain
- Treat infection
- Rule out sepsis

Medication
First Line
- Analgesia based on degree of discomfort
  - Narcotic analgesics for more severe pain
    - Oxycodone/APAP
    - Morphine/PD of IV
  - Nonsteroidal anti-inflammatory drugs
    - Naproxen
    - IV acamprosate
  - Less distress and hypotension than morphine in one study
- Antimetics (metoclopramide, ondansetron)

Second Line
- a blockers: Tamsulosin, alfuzosin, silodosin
  - Given to relieve unilateral smooth muscle spasm
  - Only label use in cases of urethral stricture
  - Alfuzosin (30 mg)
  - Silodosin (8 mg/day)
  - Tamsulosin (start 0.4 mg to max 0.8 mg/day)

Surgery/Other Procedures
- Initial stone placement for significant obstruction
  - Lithotripsy for nephrolithiasis
  - Ureteroscopy with laser lithotripsy
  - ESWL (extracorporeal shock wave lithotripsy)
  - PCNL (Percutaneous nephrolithotomy)
- Ureteral stent placement for significant obstruction
  - Balloon dilation, laser incision
  - Open or laparoscopic resection
- UPJ obstruction
  - Ureteroscopy
  - Endopyelotomy (ureterohydropaly, ureterograft)
  - Ureteral stenting for severe obstruction
- Upper tract neoplasm
  - Nephroureterectomy (open or laparoscopic)

Additional Treatment
Radiation Therapy
- N/A

Additional Therapies
- Obtain adequate drainage if necessary, especially if patient appears septic.
- Internal stenting is usually a good 1st choice
- Chronic stricture patients often have significant ureteral tortuosity making retrograde access challenging
- Percutaneous drainage
  - Can be performed with conscious sedation
  - Optimal in cases of significant extrinsic ureteral compression

Complementary & Alternative Therapies
- N/A

Ongoing Care

Diagnosis
- Depends on underlying etiology but usually good once infection treated, if present

Complications
- Persistent obstruction if left untreated
- Renal cortical loss
- Can lead to nonfunctioning kidney
  - Venous infection

Follow-Up
Patient Monitoring
- Renal/bladder ultrasound after treatment to ensure no obstruction is relieved and infection treated, if present

Patient Resources
- Urology Foundation
- Urology Health Patient Resources

**RENAL CYSTS (INTRARENAL, PERIPELVIC, AND PARAPELVIC)**

Jeffrey J. Tomaszewski, MD
Robert G. Uzzo, MD

**BASICS**

**DESCRIPTION**
- Renal cysts are fluid-filled renal structures not continuous with the nephron or collecting system
- **Simple cyst**
  - Arises from the renal parenchyma
  - Size varies, often < 2 cm but may be significantly larger
  - Typically asymptomatic, incidentally detected on CT or US
  - Can be single, multiple, and/or bilateral
  - If large, may impinge on the renal pelvis causing obstruction
  - Diagnostic US findings include a mass that is free of internal echoes (anechoic), through transmission with posterior acoustic enhancement
- **Complex cyst**
  - Features not consistent with simple cyst; raise the possibility of malignancy
  - Increased fluid density, internal thick-walled septations, thickened wall, mural projections into the lumen, calcifications, and contrast enhancement
- **Polycystic cysts are infected cysts**
- **Parapelvic cyst** (aka peripelvic, parapelvic lymphatic, parapelvic-cystic lymphangectasia, and renal sinus cysts) arise from the renal sinus

**ALERT**
Parapelvic cysts may be confused with hydroureteronephrosis-given their central location.
- **Acquired cyst**
  - Associated with chronic hemodialysis
  - Occasionally regress spontaneously
- **Boxniak classification used to classify cysts based on CT complexity and likelihood of malignancy**

**EPIDEMIOLOGY**

**Incidence**
- 0.2–2.2% from birth to 18 yr
- 20% by age 40
- 33% by age 60
- In autopsy series, 50% of patients ≥50 have ≥1 simple renal cysts
- Acquired cystic renal disease is more common among men
- Bilateral simple cysts infrequent <50 yr

**Prevalence**
- Age, a known risk factor for simple renal cysts
- Increasing age (7-fold increase from 4th–8th decade or an increased incidence from 5–38%)

**Risk factors**
- Polyposis kidney disease (autosomal dominant and recessive types)
- Hemodialysis
  - In ESRD, cysts in 8–13% prior to hemodialysis (HD)
  - 10–20% have acquired cystic renal disease after 3 yr of dialysis, 40–60% after 5 yr, and >90% after 10 yr

**Genetics**
- *ARPKD*: PKHD1 gene, chromosome 6, protein product fibrocystin
- *ADPKD*: PKD1 & PKD2 genes, chromosome 16, protein product polycystin-1, -2
- Other genetic cystic diseases: Juvenile nephronophthisis, medullary cystic kidney disease, glomerulocystic kidney disease, Von Hippel–Lindau syndrome (VHL), tuberous sclerosis, Birt–Hogg-Dubé syndrome

**PATHOPHYSIOLOGY**
- **Simple cyst**
  - Development of discrete fibrous sacs of clear fluid lined with cuboidal epithelium
  - Estimated growth rate: 2.18 mm/yr
  - Some will involute and disappear over time although most will not
  - It is controversial if renal cysts are causative agents of HTN
- **Parapelvic cysts**
  - Found on ~2% of kidneys at autopsy
  - Can be confused with hydroureteronephrosis

**ASSOCIATED CONDITIONS**
- **ADPKD** (Autosomal dominant polycystic kidney disease)
- **APKD** (Autosomal recessive polycystic kidney disease)
- **Birt-Hogg-Dubé syndrome**
- **ESRD** (End stage renal disease)
- **Tuberous sclerosis**: 20–25% of have renal angiomyolipomas
  - 20–25% of have renal cysts
  - **VHL disease**
    - Individuals develop cysts in multiple organs (kidney, pancreas, liver, epididymis)
    - Increased risk of clear cell renal cell carcinoma (RCC) in cyst wall

**DIAGNOSIS**

**GENERAL PREVENTION**
- Family members of patients with ADPKD and VHL should be screened

**HISTORY**
- Patients may present with an abdominal mass, pain, hematuria, or HTN but most are radiographically incidental
- Family member with polycystic kidney disease or other inherited cystic disease

**PHYSICAL EXAM**
- Abdominal/flank mass (narcotic)
- Often a benign exam

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urinalysis most often normal unless concurrent medical renal disease present
- Renal function tests—calculate eGFR and stage chronic kidney disease (CKD)

**Imaging**
- Ultrasound
  - Simple cyst
  - No internal echoes, distinct walls with defined margins, spherical shape with no internal echoes

**CT**
- Simple cyst
  - Have sharp walls with smooth margins, spherical shape, homogenous throughout

**MRI**
- Bosniak criteria can be applied to MRI (exception: Califications may not be well seen)
- Low signal T1, high signal T2 consistent with benign simple cyst
- Hyperdense cysts can be high signal on T1 and low on T2 but appearance depends on hemoglobin breakdown
- MRI may have a role in subsets of patients (VHL, multiple renal masses) if concern exists regarding excessive radiation due to multiple long-term imaging studies
- May be superior in characterization of internal cyst contents (blood, mucus)

**Bi- or triphasic CT represents the gold standard for distinguishing renal cysts**
- Discern between cysts and collecting system on excretory phase
- Particularly important in assessing hydronephrotic systems
- US may be misleading/difficult to interpret

**Bosniak classification system of cystic renal masses originally based on CT (image 1)**
- Category I: Benign simple cyst; thin wall without septa, calcifications, or solid components, water density, and no contrast enhancement; no further imaging needed
- Nearly all are benign
- Category II: Benign cysts with a thin thin-wall; the wall or septa may contain fine calcification, sharp margins, nonenhancing
- Category III: Wall thickened and may have thin septa or minimal smooth thickening of the septa or wall, which may contain calcification that may also be thick and nodular; no contrast enhancement, includes totally intrarenal nonenhancing complex lesions >3 cm
- These require follow-up (delayed by the F designation)
- 5–20% of Bosniak IIIIF cysts contain malignancy in wall
- Category IV: Indeterminate cysts with thickened irregular or smooth walls or septa; enhancement present
  - 40–60% of these are malignant (cystic RCC and multifocalized cystic RCC)
- Other class III lesions are benign (infected cysts and multifocalized cystic nephroma)
- Category V: Characteristics of category IV cysts plus they contain enhancing soft tissue components that are adjacent to and independent of the wall or septum
- Risk of malignancy is 85–100%
Renal Cysts (Intrarenal, Peripelvic, and Parapelvic)

Diagnosis Procedures/Surgery
- Cyst aspiration is rarely negative; fluid reaccumulates. Infected cysts may require aspiration and catheter placement.
- Infected cysts often represent calyceal diverticula.
- Cyst biopsy is difficult and frequently results in inadequate tissue for pathologic examination.
- Cytologic evaluation of fluid for malignancy or culture based on indication and characteristics of the cyst.

Pathologic Findings
- Simple renal cyst
  - Single layer of cuboidal epithelium
- Not continuous with the collecting system

Differential Diagnosis (3)
- ADPKD (Autosomal dominant polycystic kidney disease)
- ARPKD (Autosomal recessive polycystic kidney disease)
- Cystic dysplasia (septate or cystic renal dysplasia)
- Hydroureter (hydronephrosis)
- Xanthogranulomatous pyelonephritis

ADPKD (Autosomal dominant polycystic kidney disease)

Polycystic Kidney Disease, Autosomal Recessive

Polycystic Kidney Disease, Autosomal Dominant

Multicystic Dysplastic Kidney

Juvenile Nephronophthisis

Hydronephrosis (parapelvic cysts)

Renal Abscess

Urolithiasis

Pararenal (retroperitoneal or adjacent mesenteric/liver/splenic/adrenal cyst)

Sclerosing Nephronophthisis

Cystic fibrosis

Medullary Sponge Kidney

Birt–Hogg–Dubé Syndrome

VHL Disease

Tuberous Sclerosis

Renal Mass

Renal Cell Carcinoma, General

Renal Mass

Tubulointerstitial disease

Clinical/Surgical Pearls

ADPKD

Cystic kidney disease

Bosniak cyst type malignancy risk:

Benign simple cysts demonstrate little risk of progressing to malignancy.

Boasniak classification and risk of malignancy:

- Boasniak I: No risk
- Boasniak II: 5–20% risk depending on imaging characteristics
- Boasniak III: 50% risk
- Boasniak IV: 75–90% risk

Complications

- Rupture and hemorrhage with simple renal cyst; usually associated with flank pain and hematuria
- Infected renal cyst
- ADPKD

ALERT

- Associated with cerebral berry aneurysms.
- In up to 40% of patients.
- 9% mortality (subarachnoid hemorrhage).

Follow-up

- Periodic imaging of Bosniak type IV cysts
- Multiple dysplastic kidney/VHL
- Periodic sonography to monitor for neoplastic changes

Patient Monitoring

- Cystic kidney disease

Patient Resources

RENAL DYSPLASIA, HYPODYSPLASIA, AND HYPOPLASIA
Kymora Scotland, MD, PhD
T. Ernesto Figueroa, MD, FAAP, FACS

DESCRIPTION
Renal dysplasia, hypoplasia, and hypodysplasia are forms of renal dysgenesis, namely, maldevelopment of kidney size, shape, or structure.

- **Renal dysplasia**: Clinically a histologic diagnosis based on the presence of primitive renal components (ie, ducts) and embryonic-mesenchymal cells (ie, cartilage).
  - **Classification of renal dysplasia**:
    - Total dysplasia: Involves both cortex and medulla; spectrum ranging from aplastic (small and solid) to multicystic (enlarged) kidneys (eg, Multicystic dysplastic kidney [MCDK]).
    - Subtotal dysplasia: Segmental distribution in cortex and medulla.
    - Hereditary: Zellweger and Meckel syndromes.
  - **Renal hypoplasia**: Small kidneys that have normal calyces and nephrons and are not dysplastic (1).
    - **Classification**:
      - With ureteral obstruction
      - Prune-belly syndrome
      - True oligonephronia
      - Oligomeganephronia
      - Normal ureteral orifice
      - Segmental (Ask-Upmark kidney)
  - **Renal hypodysplasia**: Small kidneys that have normal nephron density despite smaller size, shape, or structure.
    - **Classification**:
      - Normal ureteral orifice: With and without obstruction
      - Ectopic ureteral orifice: With or without ureteroceles
      - Medial or caudal
      - With ureteral obstruction
      - Prune-belly syndrome
  - **Retrorenal development** is dependent on the interaction between the ureteric bud and the metanephric mesenchyme.

EPIDEMIOLOGY
Incidence
- **Prevalence**
  - **Renal dysplasia**: Unilateral or bilateral in 2–4 per 1,000 births
    - Male > Female (1.9:1)
  - **Renal hypoplasia**: Unilateral or bilateral in 2–4 per 1,000 births
    - Male > Female (1.3:1)
  - **Renal hypodysplasia**: Underdeveloped medulla
    - Male > Female (1:2)
  - **Ask-Upmark kidney**
    - Male > Female (9:1)
    - Increased with low birth weight, often present by age 2
  - **Prune-belly kidney**
    - Male > Female (1:7)
    - Commonly present >10 yr of age

RISK FACTORS
- **Vesicoureteral reflux (VUR)**
- **Posterior urethral valves**
- **Urinary abnormalities**
  - Primary megaloureter, ureteropelvic junction obstruction (UPJO), ureteroureteral reflux
- **Prune-belly syndrome**

GENETICS
- A majority of dysplastic and hypoplastic kidneys disorders are sporadic and nonheritable.
- Genetic pathways can affect ureteric bud formation, branching morphogenesis within the metanephric blastema, and normal nephrogenesis.
- Familial renal dysplasia: Heterogeneous autosomal dominant inheritance of renal agenesis, renal dysplasia, MCDK, etc., within 1 family.

PATHOPHYSIOLOGY
- **Normal metanephric differentiation requires induction via the ureteric bud (1)**.
- The branching of the collecting system, as well as nephron formation, are determined by the ureteric bud.
- **Epicrural–mesenchymal interactions and peptide growth factors play a central role in nephrogenesis**.
- **Dysplasia**: Histologically manifests as distortion of renal architecture, immature or primitive glomeruli, cartilage, and tubules encircled by fibromuscular cells (primitive ducts).
  - **Ask-Upmark kidney**: Region of nonfunctioning parenchyma.
  - **Inhibition of nephron development**
  - **Increased TGF-β**
  - **5-sided bodies and cysts**
  - **Dedifferentiation of renal cells**
  - **Hypoplasia**: Normal nephron density despite smaller size, bilateral or unilateral can be associated with reflux.
  - **Oligomeganephronia**: Reduction in nephron number and hypertrophy of each nephron.
    - Usually bilateral, but contralateral renal agenesis has been reported
    - No direct obstruction between cortex and medulla; reduced number of renal segments, small renal artery, elongated nephrons
    - **Ask-Upmark kidney**
      - Likely secondary to reflux nephropathy
    - Deep grooves on lateral convexity with underlying tubules resembling thyroid tissue
    - **Underdeveloped medulla**
    - **Anterosclerosis and juxtamedullary hyperplasia**
    - **Hypoplasia**: Most often seen in conjunction with an ectopic ureteral orifice or obstruction; extent of dysplasia correlates with degree of ureteral ectopia.
      - **Normal ureteral orifice**:
        - With obstruction: Primary obstructive megaloureter and UPJO
      - **Without obstruction**: Dwarf kidney, according to bud theory is the result of deficient metanephric blastema

ASSOCIATED CONDITIONS
- **Branchio-oto-renal syndrome**
- **Ectopic ureteral orifice**
- **Fraser syndrome**
- **Jeune syndrome**
- **Kallmann syndrome**
- **Meckel–Gruber syndrome**
- **Oxal–facial–digital syndromes**
- **Posterior urethral valves**
- **Potter syndrome**
- **Primary obstructing megaloureter**
- **Prune-belly syndrome**
- **Pulmonary hypoplasia**
- **Renal cell carcinoma**
- **Simpson–Goldblatt–Beutler syndrome**
- **Treach–Renier syndrome**
- **Ureteropelvic junction obstruction (UPJO)**
- **Venous ureteral reflux (VUR)**
- **Zellweger syndrome**

GENERAL PREVENTION
- **FNA**

DIAGNOSIS
- **History**: Systemic• Failure to thrive, abnormal growth, headaches, fever, chills, shortness of breath, nausea, emesis, anorexia, skin pallor, vision change, mental status change
- **Renal**:• Polyuria, polydipsia, abdominal pain or mass, flank pain, hematuria
- **Bilateral disease**:• Lower urinary tract symptoms (LUTS), dysuria, nocturia, incontinence

PHYSICAL EXAM
- **Abnormal weight or height**
- **Vitiligo***Hyperpigmentative***
- **Mental status**: Encephalopathic
- **RENT**: Renal opacity, papillary edema, dehydration
- **Lungs**: Crackles
- **Abdomen**: Distention, palpable mass, guarding, C/O tenderness, ascites
- **Extremities**: Pallor, peripheral edema
DIFFERENTIAL DIAGNOSIS

Pathologic Findings
- Renal dysplasia and hypoplasia
- Renal vein thrombosis
- Simple cysts
- Sporadic glomerocystic kidney disease
- Tuberous sclerosis
- UPJO
- Von Hippel-Lindau disease
- Urolithiasis
- Wilms tumor

TREATMENT

GENERAL MEASURES
Consultation with nephrology and multimodality management.

MEDICATION
First Line
Antibiotics for UTI or as prophylaxis for VUR

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Indications for nephrectomy: Pain, chronic infection, hypertension, or increasing size
- Pyeloplasty for UPJO
- Ureteral reimplantation: Reflux, primary megaureter
- Renal transplantation for end-stage renal disease
- Indications for nephrectomy: Pain, chronic infection, hypertension, or increasing size

ADDITIONAL TREATMENT
Perinatal or hemodialysis for ESRD

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Varies with degree of renal insufficiency and degree of correlated conditions.

COMPlications
Renal failure, anemia, UTI, failure to thrive

PATIENT MONITORING
- BP and growth chart annually
- Electrolytes, Cr, BUN annually
- Urinalysis and urine culture as indicated
- Bilateral disease: Renal US annually
- MICT: Renal US every 2 yr to 3 yr for diagnosis

PATIENT RESOURCES

- Q60.2 Renal agenesis, unspecified

CODES
- Q61.4 Renal dysplasia

CLINICAL/SURGICAL PEARLS

Prognosis varies; however, most patients have renal insufficiency and its sequelae.
RENAL ECTOPIA

Vani S. Menon, MD
Derek Matoka, MD

PATHOPHYSIOLOGY

Failure of ascent
- Anomalous vasculature impeding ascent; possibly and abnormally situated umbilical artery
- Thought to occur at the 4th–8th wk of gestation
- Normal kidney ascent to the level of L2 at the end of the 8th wk of gestation
- Abnormality of the ureteric bud or metanephric blastema

Fusion abnormalities occur early in embryogenesis
- Horseshoe kidney is the most common fusion anomaly
- Two renal moieties joined at lower pole in 90% of cases
- Anatomic considerations:
  - Orthotopically located adrenal gland
  - Ureter inserts into bladder in orthotopic position
  - Renal pelvis of ectopic kidney is usually anterior to the parenchyma secondary to malrotation
  - Failure of development of fascial layers in the flanks on the side not occupied by renal tissue
  - Malrotation of the ectopic kidney almost always occurs

ASSOCIATED CONDITIONS

- Recurrent urinary tract infections (UTIs)
- Nephrolithiasis
- Cloacal anomalies: 14% of these patients will have
- Genital anomalies: Estimated incidence between 20–66% of females will have uterine or vaginal ptosis of orthotopically located kidney
- Malrotated kidney
- Supernumerary kidney:
  - Usually caudad to orthotopic kidney

DIAGNOSIS

HISTORY
- UTIs (30%), vague abdominal pain or renal colic
- Incidentally during pre- or postnatal screening
- Abdominal mass, hypertension, hematuria, incontinence, renal insufficiency

PHYSICAL EXAM
- Usually normal
- May find abdominal mass or flank tenderness
- Genitourinary abnormalities

DIAGNOSTIC TESTS & INTERPRETATION

Imaging
- If kidney absent on ultrasound (US), radionuclide imaging should be performed to evaluate for an ectopic kidney
- Average differential function of ectopic kidney is 25% (1/C)
- Skeletal scintigraphy if moderate-to-severe pelvicalyceal dilation or progressive dilation found to evaluate for obstructive process
- Voiding cystourethrogram for mobile UTI and/or pelviccalyceal dilation
- If kidney is nonfunctional, computed tomography scan or abdominal US for localization
- Recent use of magnetic resonance urogram for small, poorly functioning kidneys can be utilized

Diagnosic Procedures/Surgery

Pathologic Findings

DIFFERENTIAL DIAGNOSIS
- Horseshoe kidney
- Malrotated kidney
- Supernumerary kidney:
  - Usually caudad to orthotopic kidney

RISK FACTORS

Potential relationship with maternal teratogenic exposure

Genetics

N/A

GENERAL PREVENTION

N/A
TREATMENT

GENERAL MEASURES
Specific treatment for renal ectopia itself is not indicated. However, special considerations for associated conditions may be necessary.

MEDICATION
First Line
Antibiotic prophylaxis for reflux based on clinical need

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Nephrolithiasis
  – Shock-wave lithotripsy, ureteroscopy, percutaneous nephrolithotomy (PCNL)
  – UP JO
    – <15% are due to an aberrant crossing vessel
    – Goal of management is to achieve dependent pelvic drainage
    – Dilated open or minimally invasive
      – Ureteropyelostomy
      – Endopyelotomy could be a consideration for failed pyeloplasty but is rarely indicated as the initial surgical intervention
    – Nephroureteral reflux
      – Open vs. endoscopic repair for clinically significant reflux

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Outcomes for treatment of nephrolithiasis and UPJO are comparable to management of these entities in the orthotopic-positioned kidney
- Current literature suggests no adverse effects on blood pressure or kidney function (4)
- No evidence for increased risk of malignancy

COMPLICATIONS
- Ureteral reflux
- Nephrolithiasis
  – Most likely due to urinary stasis
  – UPJO/UVJO
  – UTIs
  – Bowel in the region of the empty renal fossa
    – Traumatic injury to renal unit due to poor protection in ectopic location

FOLLOW-UP
Patient Monitoring
- Nephrolithiasis
  – Imaging by renal US and/or CT scans
  – VCUG and/or DMSA
  – Hydronephrosis
  – Renal US and/or nuclear scans
  – Yearly blood pressure measurements
  – Yearly BUN/Cr measurements

Patient Resources

  - Renal Ectopia Image 3
  - Renal Fusion Anomalies
    - UPJO
    - UTS, Complicated, Pediatric
    - Urolithiasis, Pediatric, General Considerations

CODES
- ICD9 753.3 Other specified anomalies of kidney
- ICD10 Q63.2 Ectopic kidney
  - Q63.1 Lobulated, fused and horseshoe kidney

CLINICAL/SURGICAL PEARLS
- Renal ectopia carries an increased risk of urologic abnormalities such as reflux, hydroureter, and genital abnormalities.
- Over half the cases of reflux occur in the orthotopic kidney.
- >30% of ectopic kidneys will have differential function of approximately 35%.
- An anterior renal pelvis and anomalous vasculature must be a consideration prior to surgical intervention.
- Surgical interventions for nephrolithiasis have similar success rates as for orthotopic kidneys.
RENAL FUSION ANOMALIES
Ross M. Decter, MD, FRCS
Paul H. Smith III, MD

BASICS

DESCRIPTION
- Renal fusion is a congenital condition in which the renal units are joined.
- Horseshoe kidney and crossed-fused ectopia are the most common variants.
- Horseshoe kidney:
  - Most common renal fusion anomaly
  - Poles of the kidney are fused by the isthmus
  - Fusion occurs at the lower poles in 95%
- Crossed-fused ectopia:
  - 2nd most common renal fusion anomaly
  - Kidney is on opposite side of where ureter inserts (uterus crosses midline)
  - The ectopic renal unit is fused to its companion in 90% of cases
  - Crossing from left to right is the most common morphotype

EPIDEMIOLOGY

Incidence
- Male >> female
- Horseshoe kidney occurs in 1 in every 400–500 live births
- Crossed-fused ectopia occurs in 1 in every 1,000–2,000 live births

Prevalence
- Horseshoe kidney: ~1:400–500
- Crossed-fused ectopia: ~1:3,000

RISK FACTORS
- Crossed-fused ectopia is frequently seen with vertebral anomalies such as myelomeningocele and sacral agenesis (1)
- Horseshoe kidney is present in 60% of female patients with Turner syndrome and 20% of patients with trisomy 18

Genetics
- Specific genetic causes unknown, but renal fusion anomalies commonly seen in association with a variety of chromosomal and congenital abnormalities (Turner syndrome, trisomy 18)

PATHOPHYSIOLOGY
- Metanephric blastema is the embryologic precursor to the adult kidney
- Development of the kidney begins in the 4th–5th wk with ingrowth of the ureteric bud, an outpouching of the metanephric duct, into the surrounding mesenchyme

- Proper renal development is coordinated through interactions between the metanephric blastema and ureteric bud
- The developing kidney ascends and rotates medially to reach its usual anatomic position by the 9th wk of gestation
- Several theories have been offered to explain crossed ectopia
  - One theory proposes that an abnormally oriented ureteric bud induces renal development in the contralateral mesonephric blastema
  - An alternate theory suggests that the developing kidney is channeled/displaced to the contralateral side during its ascent by the presence of an aberrant umbilical or common iliac artery or other pelvic structures
- The developing left and right metanephric blastemata are in close proximity to each other within the pelvis and, if abutting, may merge to form a horseshoe kidney or other fusion anomaly (2)

ASSOCIATED CONDITIONS
- Other congenital anomalies are present in up to a third of patients with horseshoe kidney
  - Skeletal, cardiovascular, neural tube, and anorectal anomalies are the most common
- Other GU anomalies associated with horseshoe kidney
  - Cryptorchidism or hypospadias in 4% of males

- Several theories have been offered to explain renal fusion anomalies
- Proper renal development is coordinated through interactions between the metanephric blastema and ureteric bud
- The developing kidney ascends and rotates medially to reach its usual anatomic position by the 9th wk of gestation
- Several theories have been offered to explain crossed ectopia
  - One theory proposes that an abnormally oriented ureteric bud induces renal development in the contralateral mesonephric blastema
  - An alternate theory suggests that the developing kidney is channeled/displaced to the contralateral side during its ascent by the presence of an aberrant umbilical or common iliac artery or other pelvic structures
- The developing left and right metanephric blastemata are in close proximity to each other within the pelvis and, if abutting, may merge to form a horseshoe kidney or other fusion anomaly (2)

ASSOCIATED CONDITIONS
- Other congenital anomalies are present in up to a third of patients with horseshoe kidney
  - Skeletal, cardiovascular, neural tube, and anorectal anomalies are the most common
- Other GU anomalies associated with horseshoe kidney
  - Cryptorchidism or hypospadias in 4% of males

- Several theories have been offered to explain renal fusion anomalies
- Proper renal development is coordinated through interactions between the metanephric blastema and ureteric bud
- The developing kidney ascends and rotates medially to reach its usual anatomic position by the 9th wk of gestation
- Several theories have been offered to explain crossed ectopia
  - One theory proposes that an abnormally oriented ureteric bud induces renal development in the contralateral mesonephric blastema
  - An alternate theory suggests that the developing kidney is channeled/displaced to the contralateral side during its ascent by the presence of an aberrant umbilical or common iliac artery or other pelvic structures
- The developing left and right metanephric blastemata are in close proximity to each other within the pelvis and, if abutting, may merge to form a horseshoe kidney or other fusion anomaly (2)

GENERAL PREVENTION
- Preventative measures aim to minimize risk factors for future renal deterioration
- Prophylactic antibiotics or surgical correction if VUR present
- Decompression of obstructed moieties (pyelostomy)

DIAGNOSIS

HISTORY
- Most are asymptomatic and are incidentally discovered
- May be diagnosed on prenatal ultrasonography
- Symptoms are usually the result of infection, stones, or obstruction of the abnormality positioned collecting system (UPJO)
  - Nonspecific abdominal pain, nausea, vomiting, hematuria

PHYSICAL EXAM
- Nontypical abdominal mass (hydronephrosis)

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Urinalysis (hematuria)
- Serum creatinine (elevated with obstruction)
- Complete blood count
- Serum calcium and phosphorus
- Metabolic evaluation for stone disease
- Renal function tests
- 24-hr urine collection
- Voiding cystourethrogram (VCUG): VUR present
- IVP: High incidence of VUR
- Diuretic renography (MAG3): Renal mass
- Serum electrolytes
- Serum alkaline phosphatase

IMAGING
- Renal US: Hydronephrosis
- VCUG
- Intravenous pyelography (IVP)
- Intravenous urography (IVU)
- Nephrosonography
- Diagnostic Procedures/Surgery
  - VCUG
- Nonspecific abdominal mass (hydronephrosis)
- Renal US

Pathologic Findings
- Wilms tumor in children and TCC in adults are more common in horseshoe kidneys
- Ureteric or renal carcinoma related to embryologic mechanisms, urinary stasis, or infection

DIFFERENTIAL DIAGNOSIS
- Renal mass
- Supernumerary kidney
- An accessory organ with its own blood supply and collecting system
- It may not be reniform, but possesses a distinct capsule surrounding a parenchymal mass
- Malpositioned kidney: Can look like a horseshoe kidney on radiographic imaging
RENAL FUSION ANOMALIES

TREATMENT

GENERAL MEASURES
No treatment if asymptomatic. Specific management dictated by complicating features.

MEDICATION

First Line
• Antibiotics: VUR treated the same as in those without fusion anomalies
• Antibiotic prophylaxis may be used until resolution for low-grade reflux

Second Line
N/A

SURGERY/OTHER PROCEDURES
• General operative considerations:
  – Horseshoe and ectopic kidneys often have abnormal and complex renal vasculature
  – Renal vessels may arise from the aorta, common iliac artery, or both, and typically enter the kidney anteriorly
• Angiography (including CT and MRI angiogram) may be useful to delineate renal vascular anatomy for operative planning
  – The renal pelvis and ureteropelvic junction of the horseshoe kidney often have an abnormal configuration, which can result in urinary stasis or obstruction. This anatomic abnormality contributes to the majority of the symptoms associated with horseshoe kidney, including stone formation, infection, hydronephrosis, and flank UPJO.
  – In the horseshoe kidney, the lower poles are joined by an isthmus, which is typically situated just caudal to the inferior mesenteric artery. The isthmus may be divided if necessary during nephrectomy.
• UPJO, best managed with dismembered pyeloplasty:
  – PCNL:
  – Endoscopic management of UPJO is feasible in the horseshoe kidney, including stone formation, infection, hydronephrosis, and flank UPJO.
  – Horseshoe and ectopic kidneys often have an abnormal configuration, which can result in urinary stasis or obstruction. This anatomic abnormality contributes to the majority of the symptoms associated with horseshoe kidney, including stone formation, infection, hydronephrosis, and flank UPJO.
  – The renal pelvis and ureteropelvic junction of the horseshoe kidney often have an abnormal configuration, which can result in urinary stasis or obstruction. This anatomic abnormality contributes to the majority of the symptoms associated with horseshoe kidney, including stone formation, infection, hydronephrosis, and flank UPJO.
  – In the horseshoe kidney, the lower poles are joined by an isthmus, which is typically situated just caudal to the inferior mesenteric artery. The isthmus may be divided if necessary during nephrectomy.
• Ureteroscopy:
  – ESWL:
  – It may be difficult to target stones for ESWL due to the abnormal location of the kidney. ESWL is most appropriate for stones <1.5 cm associated with undistorted collecting systems. Repeat treatments may be required in order to achieve a stone-free status (AIII).
  – Ureteroscopy:
  – Safe and effective approach for calculi associated with horseshoe or ectopic renal moieties; however, the smaller ureteroscopic instruments generally limit this approach to smaller stone burdens

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Relatively poor due to complicating features. Outcomes comparable to those for anatomically normally positioned kidneys.

COMPLICATIONS
• Possible increased risk of malignancy
• UTR
• Urothelitis
• VUR

FOLLOW-UP

Patient Monitoring
Due to slight increase in incidence of Wilms tumor in children, some advocate imaging every 6 mo once the diagnosis is made

The abnormalities and conditions for crossed fused ectopia are similar to horseshoe kidneys, and treatment often follows similar lines.

RENAL INFARCTION
Matthew A. Meissner, MD
Ganesh V. Raj, MD, PhD, FACS

PATHOPHYSIOLOGY
- The main mechanism is embolization of the renal vasculature:
  - Clot emboli are the most common (~60%)
  - Atherosclerotic emboli
  - Vegetative emboli (endocarditis)
  - Fat emboli
- Renal arterial occlusion is more common on the left side, due to the more acute angle of the left renal artery with the aorta (1)
- Acute infarction due to trauma may show a hematoma in the vessel wall (intimal flap); infarction due to clot emboli will reveal a clot, blocking the renal artery or its branches (2)
- Renal vasoconstriction from sepsis, α-adrenergics, cocaine, others

ASSOCIATED CONDITIONS
- Anemias of the aorta or renal artery
- Angina
- Atrial fibrillation
- Claudication
- Collagen vascular disease (Ehlers–Danlos, collagen vascular disorders)
- Diabetes mellitus
- Endocarditis
- Hypertension
- Hypercoagulable states (factor V Leiden, protein C or S deficiency)
- Lupus
- Myocardial infarction
- Polyarteritis nodosa
- Pyelonephritis
- Renal artery aneurysm
- Renal artery or vein thrombosis
- Sickle cell disease
- Stroke
- Trauma
- Vascular disease

DIAGNOSIS

HISTORY
- A high suspicion is mandated in patients with underlying heart disease, hypertension, or diabetes
- Suspect a ventricular thrombus in patients with a recent myocardial infarction
- Acute flank pain: ~75%
- Nausea/vomiting: ~50%
- Gross hematuria may be seen

ALER
- The symptoms associated with acute renal infarction closely mimic those of an acute episode of urosepsis or pyelonephritis resulting in delayed diagnosis. This detrimentally impacts long-term renal function and potential for recovery.

BASICS

DESCRIPTION
- Renal infarction is a rare condition that occurs secondary to any process that interrupts or hinders blood flow to the kidney causing necrosis and cessation of function
- Most commonly caused by thromboembolic phenomenon in conditions such as atrial fibrillation
- Hypertension, valvular heart disease, infective endocarditis, bacterial endocarditis, cardiac mural thrombi

RISK FACTORS
- Acute tubular necrosis
- Antiphospholipid antibody syndrome
- Atherosclerosis
- A-fib
- Chagas disease
- Cocaine abuse
- Diabetes mellitus
- Endocarditis
- Hypertension
- Hypercoagulable states (factor V Leiden)
- Lupus
- Marfan syndrome
- Myocardial infarction
- Polyarteritis nodosa
- Pyelonephritis
- Renal artery aneurysm
- Renal artery thrombosis
- Renal artery stenosis
- Resting myocardial ischemia
- Sickle cell disease (papillary necrosis)
- Stroke
- Trauma
- Vascular disease

GENETICS
- Patients with inherited hypercoagulable disorders such as factor V Leiden mutation, protein C or S deficiency, lupus, antiphospholipid antibody syndrome, nephrotic syndrome, Ehlers–Danlos, and other collagen vascular disorders are at increased risk
- Familial history of coronary artery disease, diabetes, or metabolic syndrome portends an increased risk for these diseases, and consequently, renal infarction

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - Leukocytosis: 70% of patients
  - Elevated or normal hematocrit
  - Microscopic hematuria: 80% of patients
  - Proteinuria: 90% of patients
  - Elevated LDH: 100% of patients, if LDH is elevated with normal transaminases, this is highly suggestive of renal infarction in the presence of appropriate symptoms
  - Elevated AST: 83% of patients
  - Elevated ALT: 66% of patients
- Imaging:
  - The best study is abdominal CT with and without IV contrast
  - Classic CT findings of renal infarction:
    - Lack of IV contrast uptake in affected kidney
    - Areas of low attenuation secondary to local edema
    - Sharply demarcated, wedge-shaped area of decreased activity in affected kidney
    - Cortical rim sign: Perfusion to infarcted aspect of kidney
    - Elevated AST: 83% of patients
    - Elevated ALT: 66% of patients
- Physical exam:
  - Noncontrast CT, often obtained due to suspicion for renal calcit, will fail to show a renal infarct

Diagnostic Procedures/Surgery
- Ultrasonography will diagnose any renal vascular occlusion and allow for intervention
- ECG to diagnose arrhythmias
- Echocardiography for diagnosis of mural thrombosis and valvular vegetations
Pathologic Findings
- Acute histology demonstrates apoptosis of glomerular and renal tubal epithelial cells
- Chronic changes include necrosis and nuclear loss in glomerular and tubules

DIFFERENTIAL DIAGNOSIS
- Acute abdominal processes (acute mesenteric ischemia, appendicitis, bowel obstruction)
- Cystic renal disease
- Renal artery stenosis
- Renal calculus
- Renal tumor
- Renal vein thrombosis

TREATMENT
GENERAL MEASURES
- The optimal therapy for renal infarction is not clear
- Initial therapy includes supportive measures with IV fluids and pain control
- Since thromboembolic disease is the most common cause of renal infarction, primary anticoagulation is considered first line
- Other acute treatment options include thrombolysis, endovascular stenting, and thrombectomy

MEDICATION
First Line
- Antihypertensives to control hypertension
- Anticoagulation therapy
  - Hirudin: Start with a bolus of 80 U/kg followed by a continuous infusion titrated to a therapeutic aPTT
  - New oral anticoagulants
- Continue in patients with known causes of thromboembolic disease

Second Line
- Thromolytic therapy may be used, especially in unstable patients
  - Direct intravenous infusion to limit systemic side effects
  - Many contraindications: Cerebral malignancy or AVM, history of cerebrovascular disease, GI bleed, active hemorrhage, or active dissection

SURGERY/OTHER PROCEDURES
- Surgical intervention is not considered a primary treatment for thromboembolic renal infarction.
- Exceptions include:
  - Young patients diagnosed within 6 h of the infarct
  - Bilateral infarcts or infarcts in a solitary kidney
  - For traumatic injuries leading to renal infarction (avulsion of the renal pedicle), open surgical repair may be attempted during exploration for other injuries

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Percutaneous angioplasty of the renal artery or thrombectomy

COMPLEMENTARY & ALTERNATIVE THERAPIES
N/A

ONGOING CARE

PROGNOSIS
- The duration of renal ischemia is the critical factor in determining prognosis
- Prognosis also depends on the cause of the infarct and the amount of parenchyma affected
- Patients often die of illness related to the concomitant medical conditions causing the infarct

COMPLICATIONS
- Chronic renal insufficiency
- Renal amyloidosis
- Hypertension

FOLLOW-UP
Patient Monitoring
- Regular blood pressure monitoring to assess for new-onset hypertension following infarct
- Follow-up imaging to monitor the progression or recession of an infarct
- Medical therapy for underlying condition that led to the infarct
- Monitoring of serum creatinine

Patient Resources
N/A

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Flank Pain
- Renal Colic
- Renal Infarction Image
- Renal Trauma, Adult
- Renal Trauma, Pediatric
- Renal Artery Stenosis/Renovascular Hypertension
- Sickle Cell Disease, Urologic Considerations

ICD9
- 441.3 Atherosclerosis of renal artery
- 584.5 Acute kidney failure with lesion of tubular necrosis
- 593.81 Vascular disorders of kidney

ICD10
- N17.0 Acute kidney failure with lesion of tubular necrosis
- N35.3 Acute kidney failure with tubular necrosis
- N28.0 Ischemia and infarction of kidney

CLINICAL/SURGICAL PEARLS
- Renal infarction is most commonly due to thromboembolic disease from underlying medical conditions.
- Prompt diagnosis is paramount for preserving renal parenchyma and function.
- Signs and symptoms may mimic more common GU or intra-abdominal pathology.
- Renal infarction should be in the initial differential diagnosis of nephrolithiasis and pyelonephritis.
- Anticoagulation therapy is the primary form of treatment for renal infarction.
RENAL INFARCTION

BASICS

DESCRIPTION

- Most renal masses are benign or malignant, cystic (simple or complex) or solid, unilateral or bilateral, single or multifocal, primary or metastatic.
- Most common renal mass on imaging: Benign cysts (60–70%)
- Most common renal carcinoma (RCC) are now detected incidentally (up to 70%)
- Most common malignant renal mass in RCC (90%), ureteral (5–15%), and kidney (4–8%)
- Asymptomatic patients (CT screening for colon cancer) may have incidental renal masses (5% of time: 90% determined to be benign, 10% immediately following biopsy).
- Most common renal masses in children: Hemangioblastoma (a “pseudoaneurysm”), multicystic dysplastic kidney (MCKD), and Wilms tumor (WT).
- Anjajymphoma (AA) is most common benign renal tumor in children in addition to onychomatricoma.

EPIDEMIOLOGY

- RISK FACTORS:
  - Genetics:
    - TSC1/TSC2 (50:50), chromosome 16 & TSC same risk for RCC as general population based on other factors.
    - Folliculin (papillary type 2)—chromosome 1q42 (fumarate hydratase)
    - Chromophobe (7q31): familial leiomyomatosis
    - Hereditary papillary RCC (papillary type 1—chromosomal locus 6p12.2) expressed via Potter’s sequence: VH1 (75%); TSC, 60% (75% TSC gene loss next to FH1; medullary cystic kidney disease (MCDK) (chromosome 3p21), McCRD (chromosome 16q12).
  - WT: WT1 (11p13)/WT2 (11p15), tumor suppressor gene, associated with AMHR, Deny-Brock, Beckwith-Wiedemann (BW), mixed pentalogy dysplasia (MDM), retinoblastoma.

PATHOPHYSIOLOGY

- Renal cysts: Structural abnormalities in the nephron causing fluid to accumulate.
- WT encodes a zinc-finger transcription factor that is expressed in the kidney and gonads and is necessary for urogenital development and nephrogenesis. Considered tumor suppressor gene but only 20% of Wilms have identifiable WT1 mutation. Unidentified breastalna, epithelial, or stroma leads to cancer.
- VHL: HIF-1–mediated VEGF angiogenesis upregulated because normal VHL protein-mediated degradation of HIF-1 decreased due to mutation in VHL.
- AML: Component vessel does not have normal wall and prone to bleeding when mass size > 3 cm (prophylactic intervention at 3.4–4 cm).
  - RCC: Clear cell 80% (proliferal tubule), papillary 15% (proliferal tubule), chromophobe 5% (collecting duct), collecting duct carcinoma < 1%, medullary renal carcinoma < 1% (malignant cell).
  - Unreacted small renal masses (<2 cm), <4 cm, unreliable to metastatize (<1%) at 3 yr but size and growth rates are variable and not predictive.
  - RCC size at diagnosis can predict subsequent mets:
    - <3 cm, 0.2% (2–5 cm), 2% (5–7 cm), 7% (>7 cm), 20%.

ASSOCIATED CONDITIONS

- Kidney failure (APN), papillary RCC.
- Congenital diseases (Wilms, AMHR, TCC, BWS, BLS, Li–Fraumeni, Cowden syndrome).
- Von Hippel–Lindau (blue cell RCC).
- Cerebellar lesions (APNDS).
- Sickle cell disease (medullary RCC).
- Hereditary kidney polycystic (RCC).

GENERAL PREVENTION

- Early screening if genetic predisposition high.
- In VHL remove only tumors (>7 cm).
- Consider CT chest no contrast in patients at risk for RCC.

DIAGNOSIS

- Most RCC patients asymptomatic when imaging detected incidentally.
- Cough or bone pain (mets).
- Flank pain, hematuria (2 of RCC triad of flank pain/hematuria/mass).<10% of patients with RCC.

PHYSICAL EXAM

- Skin (VN: TSC adenoma sebaeum & 2nd leaf spot; schist and papules; finger & hair nail deformities).
- With BHD manifestations.
- Lung exam (BHD associated with pneumothorax).
- Neuraxial or Venenomeat bias (VHL): arterial and venous system.
- Renal mass (most of RCC, >10%), more common in Wilms tumor.
- Signs of comorbid conditions that will increase peri-op surgical risk (CVA, CAD, HTN, DM, COPD).
- Paraneoplastic signs:
  - Hypertension (RCC, and Pheo too).
  - Cachexia, weight loss (check albumin).
  - Hypothyroidism (also part of TSC & VHL).
- Signs of anemia.

DIAGNOSTIC TESTS & INTERPRETATION

- Lab:
  - Urine analysis: Hematuria keeps RCC, AML, AML in the differential diagnosis; nitrite and leukocyte esterase positive suggest infection (renal abscess, etc.)
  - Voided urine cytology: May detect TCC of urinary tract (not useful if “atypical”).
  - BUN & creatinine in RCC, renal function tests (BUN and creatinine).
  - Increased LFTs (Stauffer syndrome: Reversible hepatic dysfunction not due to liver mets).
  - Serum calcium: May be elevated in RCC secondary to parathyroid suppression.

- Imaging:
  - CT scan with and without contrast is gold standard for renal masses (10 Houndfield unit = 1 mm of tissue; enhancement = 80% neoplasms) (25–35 mSv effective radiation).
  - CT scan with above plus delayed excretory phase for upper tract neoplasms.
  - Bone scan CT classification (1 and 2 benign, no follow-up; 3F indeterminate, CT > 6 mm/malignant.
  - CIN risk at delayed nephrogenesis: 1 in 60.
  - CIN risk at follow-up: 0.6% if GFR < 30; 60 if GFR < 15; 75 if GFR < 10.
  - CIN risk for contrast-induced nephropathy (CIN) leading to dialysis if GFR < 30.
  - CIN risk increase if GFR < 30.
  - CIN risk increase if GFR < 15.
  - CIN risk increase if GFR < 10.

- Renal masses:
  - Bosniak CT classification (1 and 2: benign, no follow-up; 3F indeterminate, CT > 6 mm/malignant).
  - 3F: Malignant.
  - 4F: Malignant (surgical).

- Biopsy:
  - Staging CT classification.
  - CT whole abdomen.

- HYPOUSIA:
  - VT scan.

- Nephron sparing (ARN, BPH, VHL).
  - Patients on dialysis can get CT without need for immediate dialysis.
  - Consider CT chest no contrast in patients at risk for mets (CIR misses 10%).
Renal Carcinoma

Differential Diagnosis

Ref: 2012 EAU Guidelines; http://www.uroweb.org/guideline/10_Renal_Carcinoma_L.pdf

ICD10: C64.9 Malignant neoplasm of unsp kidney, except pelvis

ICD9: 189.0 Malignant neoplasm of kidney, except pelvis

Patient Monitoring

- AML: Renal US every 6–12 mo
- Poor surgical candidate with STM imaging every 6 mo alternating with renal US and CT scan with yearly CBF or chest CT
- Stage 1–3 RCC, 20–30% relapse, lung most common (50–60%), median relapse 1–2 yr: evaluate every 6 mo for 2 yr, then annually.
- Stage 4: RCC flu dependent on primary treatment and provider dependent.

Patient Resources

Kidney Cancer Association www.kidneycancer.org

Additional Reading

Renal Infarction

Renal Lesions Suspect for RCC are treated surgically (laparoscopically or open) usually with radical nephrectomy or partial nephrectomy (PNx). Phb use dependent on surgeon experience and location of tumor to hilar; most 3–4 cm (T1).

PNx decreases long-term risk of CVD mortality and ESRD vs. nephrectomy

Most recommended surgery for Borisak II (50% malignant) at IV cysts (>100%) TCC, of the renal pelvis; by endoscopic ablation for small superficial lesions (low-grade Ta), or radical nephronectectomy

Asymptomatic AML: 3.5 cm or small symptomatic lesions are treated by embolization, partial nephrectomy, or nephrectomy

Painful simple renal cysts and infertile cysts: Percutaneous aspiration and sclerotherapy

Although cytodiagnostic nephrectomy is debated in path-0–2,3A, FDA approval of TKI & mTOR inhibitors based on studies where almost half patients had received a nephrectomy

First Line

- Usually used for advanced mRCC
- Sunitinib or sunitinib – 5 Ph: 1st line in low/intermediate risk
- Temsirolimus: 1st line in high risk
- Pazopanib: 1st line and after cytokine failure

Second Line

- Stabilized: 2nd line after cytokine failure
- Everolimus: 2nd line after TKI

Additional Treatment

Radiation Therapy

- Radiation used in gynecologic tumors: Wilms stage 3–4, all clear cell and rhabdoid stages
- Metastatic RCC for aiv/CNS in adults

Additional Therapies

- RCC: Embolization prior to nephrectomy not beneficial but can be palliative for pain and/or bleeding if nonsurgical candidate
- Aldosterone (or radio frequency) of smaller renal masses (< 3 cm) may be considered in selected cases (elderly, poor surgical risk) (1)

RENAL MASS, INTRAOPERATIVE CONSULTATION

Mark R. Anderson, MD, MSc
Anthony T. Corcoran, MD
Robert G. Uzzo, MD

BASICS

DESCRIPTION
• Most renal masses are incidentally found preoperatively on routine axial imaging (eg, CT or MR of the abdomen).
• Although rare today, some renal masses are now identified preoperatively.
  – Typically associated with trauma or urgent cases where preoperative imaging was either not done or inadequate for renal visualization

EPIDEMIOLOGY
Incidence
• Renal cell carcinoma (RCC) – 62,933 estimated new cases in 2014 (US data) – Primarily occurs in 6th or 7th decade – Male > female (3:2) – 4% of RCC are familial; majority are sporadic – 10–20% higher incidence in African Americans

Prevalence
N/A

RISK FACTORS
• RCC
  – Family history, smoking, obesity, hypertension, and end stage renal disease (ESRD)
  – Intraoperative renal mass consult, risk factors include:
    – Pre-existing nonrenal primary cancer
    – Positive metastatic lesion on kidney
    – Inheritable tumor syndrome
    – Associated renal tumor component
  – Renal insufficiency preventing use of contrast during imaging
  – Centrally located or small tumors initially missed on imaging

PATOPHYSIOLOGY
N/A

ASSOCIATED CONDITIONS
• Polycystic kidney disease
  – Autosomal dominant (autosomal dominant polycystic kidney disease) or recessive (autosomal recessive polycystic kidney disease)
  – Inheritable tumor syndromes with renal and extrarenal manifestations
  – von Hippel–Lindau (VHL) gene (17p11)
    – Cystadenoma, lung cysts, spontaneous pneumothorax, colonic polyps, or cancer
  – Hereditary leiomyomatosis and renal cell cancer syndrome (HLRCC) gene, 1q42 (aka: Reed’s syndrome)
    – Uterine leiomyoma and leiomyosarcoma
  – Cystic fibrosis affects renal and extra renal manifestations
  – Hereditary hyperparathyroidism (parathyroid adenoma or parathyroid cancer)
    – Parathyroid hormone (PTH)
    – Fibrous dysplasia and mandibular and maxillary tumors
    – Uterine tumors
    – Papillary thyroid carcinoma with associated papillary renal neoplasm
    – Papillary thyroid cancer, nodular thyroid disease
    – Tuberculosis (TBC), TB43
  – Familial angiomyolipoma, subcutaneous fibroma, hypoglycemia and café au lait spots, cardiac rhabdomyoma, scoliosis, mental retardation, CNS tubers, lymphangiomyomatosis

  – VHL (VHL gene, 3p25)
    – Renal and CNS hemangioblastomas, pheochromocytoma, pancreatic cyst and endocrine tumor, endolymphatic sac tumor, epididymal and broad ligament cystadenomas

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
• Obtain history from operative team and review available medical and endocrine records
  – Prior or current cancers
  – Inheritable tumor syndromes
  – History of renal or abdominal trauma

PHYSICAL EXAM
• Intraoperative evaluation—location of mass
  – Check adrenal
  – Intravenous
  – Extrarenal within Gerota fascia
  – Percutaneous
  – Renal pelvis

DIAGNOSTIC TESTS & INTERPRETATION

Lab
  – Serum creatinine and eGFR

Imaging
• Review all preoperative ultrasound (US), contrast-enhanced CT, and/or MR if available
  – If serial images available, determine growth rate to help define risk (1.0)
  – Average yearly linear growth rate of 0.3 cm for all masses vs. 0.8 cm found in patients with progression
  – Masses with no growth under surveillance unlikely to metastasize

• Intraoperative US with color Doppler (use laparoscopic or finger probe in open surgery)
  – Features suggesting malignant pathology
    – Purely cystic lesions without septation can be observed
    – Renal lesions with solid elements
    – Color Doppler also useful to:
      – Assess flow to (splenolateral and contralateral kidney
      – Differentiate an isoechoic lesion with renal parenchyma since vessels are displaced around solid renal masses
      – Identifies deep vessels near the wall of the lesion that may be encountered during excision

DIAGNOSTIC PROCEDURES/SURGERY

ALERT
• Obtain all available information on renal function.
  – Calculate overall renal function (GFR— Cockcroft–Gault equation; calculators available online) and classify CKD status
  – Status of contralateral renal unit presence, flow, and function

GENERAL ALERT
• Renal function—can estimate percent functional volume preservation if partial nephrectomy planned as volume loss correlates well with ultimate renal function after partial nephrectomy (3%)

Renal biopsy and frozen section analysis
  – Obtain core biopsy with biopsy gun
  – ~20% of intraoperative frozen sections of renal lesions nondiagnostic (4)
  – Management options include active surveillance, ablation, or extirpation (Note: Renal biopsy and frozen section analysis yield poor tumor grade information)

DIAGNOSTIC PROCEDURES/SURGERY

Pathologic Findings
• Approximately 14% of incidentally found renal masses are benign depending on size (10)
  – 68% clear cell RCC
  – Positive association between tumor size and:
    – Rates of clear cell RCC
    – Appearance grade for clear cell RCC
    – Tumor stage

DIFFERENTIAL DIAGNOSIS

Lab
  – Blood glucose, electrolytes, calcium, creatinine, and/or eGFR

IMAGING
• Renal ultrasound
  – Assess for hydronephrosis, cystic lesions, or solid renal masses

DIAGNOSTIC PROCEDURES/SURGERY

ALERT
• Obtain all available information on renal function.
  – Calculate overall renal function (GFR— Cockcroft–Gault equation; calculators available online) and classify CKD status
  – Status of contralateral renal unit presence, flow, and function

DIAGNOSTIC PROCEDURES/SURGERY

Pathologic Findings
• Approximately 14% of incidentally found renal masses are benign depending on size (10)
  – 68% clear cell RCC
  – Positive association between tumor size and:
    – Rates of clear cell RCC
    – Appearance grade for clear cell RCC
    – Tumor stage

DIFFERENTIAL DIAGNOSIS

Lab
  – Blood glucose, electrolytes, calcium, creatinine, and/or eGFR

IMAGING
• Renal ultrasound
  – Assess for hydronephrosis, cystic lesions, or solid renal masses

DIAGNOSTIC PROCEDURES/SURGERY

ALERT
• Obtain all available information on renal function.
  – Calculate overall renal function (GFR— Cockcroft–Gault equation; calculators available online) and classify CKD status
  – Status of contralateral renal unit presence, flow, and function

DIAGNOSTIC PROCEDURES/SURGERY

Pathologic Findings
• Approximately 14% of incidentally found renal masses are benign depending on size (10)
  – 68% clear cell RCC
  – Positive association between tumor size and:
    – Rates of clear cell RCC
    – Appearance grade for clear cell RCC
    – Tumor stage
SURGERY/OTHER PROCEDURES

Avoid the following:
- If no films, and cannot postpone intervention,
- If unable to defer treatment—assess presence, function, and anatomy of both kidneys and consider biopsy
- Look at available films to see if pre-contrast post phases available
  - If preoperative imaging suggests a solid enhancing mass amenable to partial nephrectomy
  - Consider intraoperative biopsy and frozen section analysis
  - Reasonable to perform partial nephrectomy if no family discussion (if present)
  - Do not get fooled by hyperdense cyst or pseudotumor—can appear on CT
- If no films, and cannot postpone intervention, consider biopsy
- If solid elements with flow on Doppler US, normal consider biopsy
- If preoperative imaging suggests a solid, enhancing mass amenable to partial nephrectomy
- Do not get fooled by hyperdense cyst or pseudotumor—can appear on CT

Surgical approach
- ± Radical nephrectomy
- Partial nephrectomy
- Assume presence, flow, or function of contralateral kidney
- Perform a radical nephrectomy because technically easier
- Unless absolute indication for radical nephrectomy, then intervene
- Consider intraoperative biopsy and frozen section analysis
- Major complications, including urine leak, increase with increasing tumor complexity
  - Low complexity—4%
  - Moderate complexity—11%
  - High complexity—22%

FOLLOW-UP

Patient Monitoring
- NCCN guidelines (level of evidence 2B—lower level but consensus recommended)
  - Every 6 mo for 2 yr, then annually for 5 yr
  - History and physical exam
  - Comprehensive metabolic panel
  - At 2 yr as indicated based on recurrence risk
  - Chest and abdominal MRI pelvic imaging
- Risk-based follow-up clinical practice guidelines operationalized at www.cancermonograms.com

Patient Resources

TREATMENT

GENERAL MEASURES
- What to do if called to the operating room emergen-
  - If patient unstable and involved kidney unjured, defer to later date
  - If films unavailable, safely defer if possible

Extirpative procedures
- Avoid the following:
  - If no films, and cannot postpone intervention,
  - If unable to defer treatment—assess presence, function, and anatomy of both kidneys and consider biopsy
  - Look at available films to see if pre-contrast post phases available
  - If preoperative imaging suggests a solid enhancing mass amenable to partial nephrectomy
  - Consider intraoperative biopsy and frozen section analysis
  - Reasonable to perform partial nephrectomy if no family discussion (if present)
  - Do not get fooled by hyperdense cyst or pseudotumor—can appear on CT

**GENERAL PREVENTION**

No preventative strategies have been described. Relatives of those with genetic syndromes may be screened.

**ASSOCIATED CONDITIONS**

- Most usually sporadic
- BHD
- Autosomal dominant
- Mutation in gene for folliculin
- Renal tumors
- Chromophobe/oncocytoma
- Spontaneous pneumothorax, lung cysts
- Fibrofolliculomas, especially on face

**DIAGNOSTIC PROCEDURES/SURGERY**

- Percutaneous biopsy
- May be useful to include metastasis to kidney based on patient history
- May guide management of poor surgical candidates
- Pitfalls of biopsy
- Difficult to distinguish oncocytoma from chromophobe RCC
- Coexistence of RCC and oncocytoma in up to 10% cases

**DIAGNOSIS**

**HISTORY**

- Most patients asymptomatic
- Incidentally detected
- Gross hematuria/painful flank mass rare
- Family history of renal tumors, fibrofolliculomas, lung cysts/pneumothorax—rule out BHD

**PHYSICAL EXAM**

- No specific findings for sporadic oncocytoma
- Polypoid flank mass rare
- Dermatological exam if suspected BHD

**DIAGNOSTIC TESTS & INTERPRETATION**

- No lab test can identify renal tumor as oncocytoma
- Laboratory panel as with any newly diagnosed renal mass
- Cannot be used to reliably distinguish oncocytoma from RCC
- CT with and without IV contrast
- Usually not helpful in evaluation of renal mass
- MRI
- Resist enhancement of mass ± central scar
- May guide management of poor surgical candidates
- Cannot be used to reliably distinguish oncocytoma from RCC
- US
- Test of choice with IV contrast allergy, renal insufficiency
- Renal angiogram
- Test of choice with IV contrast allergy, renal insufficiency
- ROC for solid renal mass
- Central scar within mass often seen in oncocytoma, but this can be confused with necrosis, commonly seen with RCC
- Lab
- CBC, chemistry panel, LFTs
- Colloidial iron stain positive in chromophobe RCC but not oncocytoma
- Chromophobe RCC is aldesleukin, cytokeratin 7 positive
- CD82 and epithelial-related antigen (MOC31) may be helpful in the distinction between chromophobe RCC and renal oncocytoma
- Gene expression differences are being explored
- The World Health Organization (2004) renal tumor classification indicates renal oncocytomas are benign neoplasms. In the past some renal oncocytomas were classified as malignant.
- This may have resulted from confusion with clear cell renal carcinomas with eosinophilic component or due to eosinophilic chromophobe RCC (low metastatic potential)

**DIAGNOSIS**

**HISTORY**

- Most patients asymptomatic
- Incidentally detected
- Gross hematuria/painful flank mass rare
- Family history of renal tumors, fibrofolliculomas, lung cysts/pneumothorax—rule out BHD

- The World Health Organization (2004) renal tumor classification indicates renal oncocytomas are benign neoplasms. In the past some renal oncocytomas were classified as malignant.
- This may have resulted from confusion with clear cell renal carcinomas with eosinophilic component or due to eosinophilic chromophobe RCC (low metastatic potential)
Ongoing Care

**PROGNOSIS**

- Oncocytoma is uniformly considered a benign tumor and surgical removal is curative.
- Multiple series report no metastases or death from oncocyotma on long-term follow-up.
- Older, rare reports of metastasis may represent unrecognized, low-grade RCC (6,7).
- Risk of metachronous oncocytoma 4–6%.

**COMPLICATIONS**

- Pelvic and/or extrapelvic complications uncommon.
- Pelvis may be spared with partial nephrectomy whenever feasible based on size and location.
- Long-term surveillance required for partial nephrectomy.
- Chronic renal insufficiency/dialysis may be needed.

**FOLLOW-UP**

- Patient monitoring
  - Long-term surveillance of renal units for metachronous tumor development and coexistent RCC.
- Serum creatinine, urinalysis, chronic renal insufficiency/dialysis.

**PATIENT RESOURCES**

- Kidney Cancer Association
  - www.kidneycancer.org/
- Patient Monitoring
  - Recommended annually to semiannually.

**EXERCISES**

- Pelvic and/or extrapelvic complications uncommon.
- Pelvis may be spared with partial nephrectomy whenever feasible based on size and location.
- Long-term surveillance required for partial nephrectomy.
- Chronic renal insufficiency/dialysis may be needed.

**ADDITIONAL READING**

**REFERENCES**

**CODES**

ICD9

237.0 Benign neoplasm of kidney, except pelvis

ICD10

-D30.0 Benign neoplasm of unspecified kidney
-D30.1 Benign neoplasm of right kidney
-D30.2 Benign neoplasm of left kidney

**CLINICAL/SURGICAL PEARLS**

- Oncocytoma is a benign solid renal lesion.
- No imaging study reliably differentiates oncocytoma from RCC. The CT finding of a central scar, previously felt to be specific for oncocytoma, has been found with RCC, and this finding is not specific.
Sarcomas exhibit aggressive local growth with high rate of local recurrence, even in the event of negative surgical margins, due to a tendency for "skip lesions."
Primary renal sarcoma is extremely rare. Primary renal sarcoma (such as leiomyosarcoma or liposarcoma) with secondary renal invasion is the more common clinical presentation.

**TREATMENT**

**GENERAL MEASURES**
- In adults, the lesions are usually approached as for RCC, with surgical excision being 1st-line therapy, as the histology of lesion is rarely known preoperatively [38].
- Masses tend to be quite large, presumably due to rapid growth pattern.
- The primary treatment of renal sarcomas is surgical excision. Local recurrences should be resected when feasible.
- The role of adjuvant and neoadjuvant therapy in the adult population is poorly understood.

**MEDICATION**

**First Line**
- Doxorubicin and vincristine are used for more favorable stages of Wilms, with the addition of doxorubicin and abdominal radiation for more advanced stages.
- Doxorubicin, vincristine, and etoposide have been used with adult sarcomas; however, response rates at best are poor.

**Second Line**

**SURGERY/OTHER PROCEDURES**
- Mainstay of treatment for all sarcomas involving the kidney is radical nephrectomy with excision of entire tumor mass, which may require resection of adjacent organs. In some cases, partial nephrectomy may be possible [39].
- Wide excision is the preferred approach due to sarcoma’s tendencies toward skip lesions.
- Sarcomas tend to surround the renal vasculature as well as surrounding vascular structures.
- No defined role for lymphadenectomy.
- Preoperative chemotherapy is given in advanced cases of Wilms to downstage prior to surgery, usually with external radiation therapy. In bilateral disease, nephron sparing is indicated.

**ADDITIONAL TREATMENT**

**Radiation Therapy**
- Sometimes employed in management of Wilms tumor postoperatively. Radiation of the tumor bed is indicated if the tumor extended beyond the renal capsule to involve adjacent organs or lymph nodes.
- Radiation therapy after surgery in adult sarcomas may reduce local recurrences.

**Additional Therapies**
- N/A

**COMPLEMENTARY & ALTERNATIVE THERAPIES**
- N/A

**ONGOING CARE**

**PROGNOSIS**
- Adult sarcoma, especially high grade, have a generally poor prognosis, with 5-yr survival rates of approximately 50%.
- Poor prognostic variables include high-grade histology, metastases at presentation, large tumor size, and incomplete resection/margin positivity.
- Local recurrence alone is associated with a better survival rate than local recurrence with concomitant metastasis.
- Pediatric patients with Wilms tumors can expect a >90% cure rate, but prognosis for clear cell sarcoma and especially rhabdoid tumors is much worse.

**COMPLICATIONS**
- Children should be monitored for long-term effects of radiation and/or chemotherapy (such as cardiac dysfunction, HTN, secondary malignancies, endocrinologic abnormalities, and ovarian or testicular failure).

**FOLLOW-UP**
- Careful patient monitoring is essential due to the high recurrence rate.
- Adults: Close follow-up for 2–5 yr
  - CBC every 3–6 moths
  - Abdominal CT every 3–6 moths
  - No specific tumor markers to follow
- Children: Same as adults. Try to limit studies such as CT due to long-term ionizing radiation risks.

**Patient Resources**
- Kidney Cancer Association (www.kidneycancer.org/)

**ICD9**
- 171.5 Malignant neoplasm of connective and other soft tissue of abdomen
- 236.91 Neoplasm of uncertain behavior of kidney and ureter

**ICD10**
- D41.0 Neoplasm of uncertain behavior of kidney

RENAL TRAUMA, ADULT
Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

BASICS
DESCRIPTION
- Renal injuries can occur by either blunt or penetrating trauma
- Renal contusions, renal laceration, and renal vascular injury are the general categories
- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (1)
  - Grade I: Subcapsular hematoma
  - Grade II: Laceration < 1 cm deep into cortex, small hematoma with Gerota's fascia
  - Grade III: Laceration > 1 cm into medullary, no collecting system injury
  - Grade IV: Laceration into collecting system, vascular segmental vein or artery injury, renal pelvis laceration and/or complete ureteral pelvic disruption
  - Grade V: Main renal artery or vein injury or thrombosis
- Most commonly injured GU organ: Kidneys are well protected in the retroperitoneum.
- 1–3% of all traumatic injuries
- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (1)

ASSOCIATED CONDITIONS
- Rib fractures
- Injury to other organ systems

DIAGNOSIS
HISTORY
- Blunt trauma history:
  - Allergies
  - Medications
  - Past medical history
  - Last meal
  - Event
  - Contrast allergy, previous renal surgeries, stones, trauma, cancer

PHYSICAL EXAM
- Primary survey
- Tachycardia and hypotension suggest major bleeding
- Abdominal tenderness
- Flank contusion
- Medial/complex laceration

DIAGNOSTIC TESTS & INTERPRETATION
- Indications for imaging
- Basic labs: Hgb, Hct, Cr, electrolytes
- Urinalysis
- Imaging
- Clinical indicators of renal injury from
- Consider placement of ureteral stent for persistent urine extravasation

PATHOPHYSIOLOGY
- Kidneys are well protected in the retroperitoneum
- Deceleration can lead to intimal tearing of renal artery and thrombosis

ASSOCIATED CONDITIONS
- Rib fractures
- Injury to other organ systems

GENERAL PREVENTION
- General trauma preventative measures
- Injuries to other organs

DIFFERENTIAL DIAGNOSIS
- Spontaneous hematuria in patients with renal mass: Traumatic or atraumatic
- Spontaneous hematuria in patients with renal mass: Traumatic or atraumatic
- Nonoperative management: Blunt trauma
- Hemodynamically stable patients with well-staged renal injury may be managed nonoperatively
- 97% blunt renal injuries can be managed nonoperatively
- Nonoperative management: Blunt trauma
- Hemodynamically stable patients with well-staged renal injury may be managed nonoperatively
- Nonoperative management: Blunt trauma
- Monitor with serial Hct and imaging
- Contrast allergy, previous renal surgeries, stones, trauma, cancer
- Contrast allergy, previous renal surgeries, stones, trauma, cancer
- CT
- Contrast enhanced is best
- Delayed films to evaluate urine leak and collecting system
- Medial urine extravasation
- IV urography (IVP)
- While mostly replaced by CT scan, single shot intraoperative IVP when pre-op imaging is not available before abdominal exploration in the OR with a film under patient on OR table
- Monitor with serial Hct and imaging
- Contrast allergy, previous renal surgeries, stones, trauma, cancer

GENERAL MEASURES
- Nonoperative management: Blunt trauma
- Hemodynamically stable patients with well-staged renal injury may be managed nonoperatively
- Nonoperative management: Blunt trauma
- Monitor with serial Hct and imaging
- Consider angiography and embolization as alternative to renal exploration
- Large perinephric hematoma and extravasation of contrast predictive for need of angiographic embolization (SIE)
- Isolated renal injuries
- Most managed nonoperatively except for grade V pedicle avulsion
- Large perinephric hematoma and extravasation of contrast predictive for need of angiographic embolization (SIE)
- Isolated renal injuries
- Most managed nonoperatively except for grade V pedicle avulsion
- Consider placement of central device for persistent urine extravasation

Epidemiology
Incidence
- 1–3% of all traumatic injuries
- Most commonly injured GU organ

Prevalence
- Estimated 245,000 cases of traumatic renal injuries per year worldwide

RISK FACTORS
- Blunt trauma
  - Rapid deceleration
  - Motor vehicle
  - Falls
  - Direct strike to abdomen or flank (sports injury related, bicycle accident, pedestrian in motor vehicle accident [MVA])
- Penetrating trauma
  - Upper abdominal
  - Stab, gunshot, or industrial injury
  - iatrogenic injury
  - Laparoscopic, endourologic, renal biopsy, percutaneous procedures
Nonoperative management: Penetrating injury

- Broad-spectrum antibiotics for penetrating injury and blunt trauma with urinary extravasation or large retroperitoneal hematoma

MEDICATION

- Renal reconstruction
- Renal exploration: Transperitoneal approach

SURGERY/OTHER PROCEDURES

- Indications for operative management
  - Relative: Urine extravasation, urinoma, nonviable parenchyma, delayed diagnosis, segmental arterial pulsatile retroperitoneal hematoma
  - Absolute: Persistent bleeding, expanding and retroperitoneal hematoma
  - Nonviable tissue
  - Isolated urine extravasation can be managed nonoperatively with expectation of 90% resolution (4)

- Early isolation of vessels
- Nonoperative management of renal injuries.

- BST for continued hematuria
- Repeat CT scan
- Serial Hct
- Hypertension
- Hydronephrosis
- Calculus formation
- Sepsis
- Perinephric abscess
- Fistula
- Pseudoaneurysm

Patient Monitoring

- Bed rest for continued hematuria
- Repeat CT scan
- Serial Hct
- Hypertension
- Hydronephrosis
- Calculus formation
- Sepsis
- Perinephric abscess
- Fistula
- Pseudoaneurysm

Patient Resources

CODES

ICD9

- 866.00 Injury to kidney without mention of open wound into cavity, unspecified injury
- 866.01 Injury to kidney without mention of open wound into cavity, hematoma without rupture of capsule
- 866.02 Injury to kidney without mention of open wound into cavity, laceration

ICD10

- S37.009A Unspecified injury of unspecified kidney, unspecified degree, initial encounter
- S37.019A Minor contusion of unspecified kidney, unspecified degree, initial encounter
- S37.029A Puncture of unspecified kidney, unspecified degree, initial encounter
- S37.039A Laceration of unspecified kidney, unspecified degree, initial encounter

CLINICAL/SURGICAL PEARLS

- CT with IV contrast is single best study.
- Most blunt renal trauma is managed nonoperatively.
- Angiembolization should be considered for stable patients with isolated renal laceration and renal vascular laceration.
- Renal vascular avulsions should be explored.
- Grade IV renal injuries may be substratified by additional findings of active vascular extravasation, perinephric hemATOMA, medial/complex laceration.
BASICS

DESCRIPTION

- Traumatic injury overall is the leading cause of childhood death in the United States.
- Pediatric renal trauma is subdivided into blunt and penetrating mechanisms of injury.
- The pediatric kidney is believed to be more susceptible to trauma vs. the adult kidney.
- Over the past 2 decades, the management of pediatric renal trauma has shifted from operative intervention to conservative management.

EPIDEMIOLOGY

Incidence
- 10–20% of all abdominal blunt trauma involves a renal injury.
- 60% of GU injuries are from blunt trauma.
- Nearly 90% of patients with GU injuries have coexisting injuries to the thorax, spine, pelvis, or intra-abdominal organs.

Prevalence
- N/A

RISK FACTORS

- Frequent GU abnormalities (ur, ureteropelvic junction obstruction horseshoe kidney vs. pelvic kidney).
- Injuries that are 5–10 times more common in pediatric patients undergoing CT for trauma.
- Classically presents with a history of hematuria disproportionate to the severity of trauma.

Decrease in physical renal protective mechanisms:
- Move pliable thoracic cage and weaker abdominal muscles.
- Less renal fat.
- Position of the kidney within the abdomen

Genetics

Disorders that lead to an increase in GU anomalies may have a greater risk for traumatic injury.

PATHOPHYSIOLOGY

- Tissue or organ injury from external source of energy.

- Grading system:
  - Grade I: Subcapsular hematoma, microscopic or gross hematuria, normal radiographic studies.
  - Grade II: Nonexpanding perirenal hematoma or cortical laceration (< 1 cm deep).
  - Grade III: Laceration – 1 cm in parenchyma without collecting system rupture or urine extravasation.
  - Grade IV: Parenchymal laceration through renal cortex, medulla, collecting system, contained main renal artery or vein hemorrhage.
  - Grade V (shattered kidney): Renal pedicle avulsion, multiple parenchymal lacerations, major injury to the renal vessels, urinary extravasation.

ASSOCIATED CONDITIONS

- Injury to other organ systems.

GENERAL PREVENTION

Measures that decrease traumatic injury in general, such as seat belts, air bags.

DIAGNOSIS

HISTORY

- Mechanism of Injury: Degree of actual traumatic injury may not correlate with the mechanism – Blunt trauma, automobile collision, sporting injuries, etc.
- Penetrating: Gunshot wound, stabwound, etc.
- Vital signs in the field:
  - Hypovolemia: Children will often have a normal BP despite a significant blood loss.
  - Up to 70% of children with grade 4 or higher renal injury may have neither gross nor microscopic hematuria.
- Medical history: Any acute or chronic medical conditions and any prior renal injury.
- Surgical history: Previous urologic procedure for reflux, stone, hypospadias, etc.
- Intra- or extravascular shunts.
- Position of consciousness.

PHYSICAL EXAM

- Vital signs and ABCD of resuscitation to stabilize patient.
- BP is often normal in severely hypovolemic children.
- Exposure: Observe for obvious signs of abdominal or thoracic trauma.
- DRE: Observe for perineal ecchymosis.
- Consider perineal ecchymosis.
- Loss of consciousness.

ALERT

- Degree of hematuria does not correlate with degree of injury.

DIAGNOSTIC TESTS & INTERPRETATION

- Lab:
  - CBC, basic metabolic profile, coagulation profile.
  - Urinalysis:
    - Unreliable in determining the extent of GU trauma.
    - Up to 70% of children with grade 4 renal trauma will have neither gross nor microscopic hematuria.
- Imaging:
  - Indications for radiographic imaging: All penetrating abdominal trauma or blunt trauma victims with 1 of the following criteria (1):
    - Significant deceleration or high-velocity injury: MVA, fall from > 15 ft.
    - Trauma resulting in fracture of the thoracic cage, spine, pelvis, or femur or bruising of the suprarenal.
    - Acute peritonitis.
    - Gross hematuria.
    - Microscopic hematuria (≥ 50 RBC/HFP) associated with shock: SBP < 90 mm Hg.
    - Delayed hemorrhage following renal trauma.

- CT:
  - Currently the most commonly used imaging modality in these patients.
  - Three-phase CT (abdomen and pelvis) ideal.
  - Clinically stable patients; most sensitive method for diagnosing and classifying GU trauma, precontrast phase, nephrographic phase after injection of contrast, and delayed images at 15–72 h.
  - Delayed hemorrhage following renal injury.
  - Follow-up images:
    - Three-phase CT. Clinically stable patients; allows for determination of renal perfusion and major renal fracture. This can be followed by a KUB to assess renal integrity.
  - Delayed CT: Obtained postoperatively after patient is stabilized or after patient is resuscitated in the ICU for full trauma evaluation; used to assess grade 3–5 renal injuries. 2–3 days post trauma to assess for baseline hematuria or urinoma.

  - Focused assessment with sonography for trauma (FAST):
    - Often combined with serial physical exams as a screening modality after blunt trauma.
    - Sensitivity ranges from 90–95% and specificity ranges from 93–100%; operator dependent.
  - Opinions vary with limited radiologic resources.
  - Angiography:
    - Used for diagnosis of arteriovenous fistula in the setting of delayed hemorrhage following renal trauma.
  - Retrograde pyelography:
    - Rule out presence of partial/traveling ureteral disruption.
    - Management of symptomatic urinoma with placement of ureteral stent.

  - Single-shot IVP:
    - Increasingly limited role.
    - Rarely used.
  - Contrast-enhanced CT:
    - Three-phase CT is indicated for patients with suspected renal injury.
    - Single-phase CT: Clinically unstable patients; allows for visualization of functioning contralateral kidney when considering unilateral nephrectomy.

  - DMSA scan:
    - Allows for quantification of renal function for grade 3–5 injuries; obtain at least 1 wk after blunt injury, also indicated.

  - Follow-up imaging:
    - Three-phase CT is indicated for patients with persistent fever, worsening flank pain, or gross hematuria > 72 h after injury.

Differential Diagnosis

Injury to other major abdominal organs in the setting of acute trauma.
TREATMENT

GENERAL MEASURES

- The major challenge facing the urologist in evaluating pediatric renal trauma is in determining when to surgically intervene. The decision to intervene operatively is based on clinical indicators: Hemodynamic stability, accurate radiographic staging, presence of associated organ injuries (2).

- In general:
  - Irrespective of the mechanism of injury and provided there are no absolute indications for abdominal exploration then all renal trauma can be observed.
  - Renal exploration and nephrostomy for grade III or higher renal injuries should be carried out if laparotomy is necessary for coexisting intra-abdominal injuries.
  - Renal exploration may be excluded in patients with concurrent intra-abdominal injuries if the urinary tract is separated from the anatomic tract by omentum or other tissue, and adequate drains are left in place.

- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (see “Renal Trauma, Adult”).

MEDICATION

First Line

- Broad-spectrum antibiotics for penetrating injury.

Second Line

- N/A

SURGERY/OTHER PROCEDURES

- Absolute indications for renal exploration:
  - Hemodynamically unstable from a renal source
  - Inability to stop persistent or delayed hemorrhage
  - Expanding or pulsatile retroperitoneal hematoma
  - Hemodynamic instability from a renal source

- Relative indications for renal exploration:
  - Known grade III or higher renal injury during blunt trauma with urinary extravasation or large retroperitoneal hematoma
  - Radiographic staging, presence of associated organ injuries (2).

- The decision to intervene operatively is based on three clinical indicators: Hemodynamic stability, accurate radiographic staging, presence of associated organ injuries (2).

- In general:
  - Irrespective of the mechanism of injury and provided there are no absolute indications for abdominal exploration then all renal trauma can be observed.
  - Renal exploration and nephrostomy for grade III or higher renal injuries should be carried out if laparotomy is necessary for coexisting intra-abdominal injuries.
  - Renal exploration may be excluded in patients with concurrent intra-abdominal injuries if the urinary tract is separated from the anatomic tract by omentum or other tissue, and adequate drains are left in place.

- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (see “Renal Trauma, Adult”).

ONGOING CARE

PROGNOSIS

- Based on the overall renal function following the traumatic injury
  - Renal vascular HTN
  - Usually develops within 36 mo after injury
  - DMSA scan is indicated to determine differential renal function
  - CT angiogram may be necessary to rule out arteriovenous fistula as the source of HTN
  - End stage renal disease
  - Bilateral renal injury
  - May require peritoneal or hemodialysis

FOLLOW-UP

Patient Monitoring

- Repeat CT of the kidney 2–3 days after trauma for grade III or higher renal injuries
- Repeat CT if patient has decreasing hemoglobin/HCT despite blood transfusion or if fistula is hemodynamically unstable
- Ambulation should resume when gross hematuria resolves.
- Strenuous physical activity should be avoided for 6 wk.

CLINICAL/SURGICAL

PEARLS

- Hemodynamically stable patients can be managed conservatively.
Renal Tubular Acidosis

Steve Dong, MD

**BASICS**

**DESCRIPTION**

- Renal tubular acidosis (RTA) is a metabolic condition characterized by abnormal urinary acidification due to a defect in renal tubules, resulting in hyperchloremic non-anion gap metabolic acidosis, increased pH of the urine.
- 4 major types of RTA are now considered to be only 3:  
  - Type I (distal): Defective distal tubular H+ secretion  
  - Type II (proximal): Defective proximal tubular bicarbonate reabsorption  
  - Type III (mixed): No longer considered as a distinct entity  
  - Type IV: Aldosterone deficiency/resistance

**EPIDEMIOLOGY**

- Most RTAs are sporadic occurring at any age. Familial RTA are rare and usually occurs in childhood.
- RTA II: Usually more predominant in males
- RTA I: More common in adults (2/3 adults; 1/3 children) and women; endemic in certain regions of Thailand
- Acquired RTA type IV:
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Lupus nephropathy
  - Hypertension
  - Diabetic nephropathy
  - Addison disease
  - Interstitial renal disease:
    - Fanconi syndrome due to toxin-related or hereditary tubular defects
    - Osteomalacia
    - Nephrolithiasis
    - Nephrocalcinosis

**ASSOCIATED CONDITIONS**

- Acquired RTA type I:  
  - Autoimmune disease: Systemic lupus erythematosus (SLE), Sjögren syndrome, primary biliary cirrhosis, chronic active hepatitis  
  - Chronic pyelonephritis
  - Diabetes mellitus
  - Hypothyroidism

- Acquired RTA type II:  
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Tubulointerstitial nephritis and interstitial fibrosis
  - Gordon syndrome
  - Sickle cell nephropathy
  - Diabetic nephropathy

**DIAGNOSIS**

**HISTORY**

- Failure to thrive, rickets, and osteomalacia in children
  - Anorexia, nausea, vomiting
  - Weakness and polyuria due to potassium loss
  - Constipation
  - Polydipsia
  - History of hematuria, urinary tract infections (UTIs), passage of stones in urine
  - History of recurrent, familial, or childhood renal stone disease
  - Ask about systemic diseases causing RTA

**PHYSICAL EXAM**

- Urologic exam of genitalia, suprapubic area for swelling and tenderness
- Exam for osteomalacia, hypokalemic muscle weakness, and growth retardation
- Exam for other systemic diseases

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urine pH (fasting, under 6, pH water):  
  - pH < 5.5: Complete type I RTA  
  - pH > 5.5, but systemic acidosis mild or absent: Ammonium chloride loading test and measure urinary bicarbonates; failure of urine pH to go below 5.5 is diagnostic of RTA type III

- RTA II is diagnosed by bicarbonate loading test:
  - After IV bicarbonate infusion, fractional excretion of bicarbonate may be less than 15%.

**PATHOPHYSIOLOGY**

- Type I (distal) tubular acidosis: Secondary to impaired ability to secrete hydrogen ions into the distal tubule or collecting duct. Urine pH may be < 5.5.
- Type II (proximal) tubular acidosis: Impaired bicarbonate absorption in the proximal tubule. Urine pH may be < 5.5.
- Type IV: Presence of aldosterone resistance or deficiency leading to hyperkalemia (not seen in type I and II) along with acidosis. Urine pH may be < 5.5.

**GENERAL PREVENTION**

**RISK FACTORS**

- Genetic disorders
- Secondary to systemic disease. See “Commonly Associated Conditions.”

**GENETICS**

- Familial RTA I (1):  
  - Autosomal dominant (AD) form is associated with mutation in the vacuolar H+ATPase (V-ATPase) gene and associated with sensorineural deafness
  - Familial RTA II: Associated with pseudohypoaldosteronism type I

- Familial RTA III:  
  - Autosomal recessive (AR) form is due to a mutation in the B1 or H+ATPase (V-ATPase) gene and associated with sensorineural deafness
  - Autosomal dominant (AD) form is associated with cerebral calcification

- Familial RTA IV: Associated with pseudohypoaldosteronism type I

- Acquired RTA type I:
  - Autoimmune disease: Systemic lupus erythematosus (SLE), Sjögren syndrome, primary biliary cirrhosis, chronic active hepatitis
  - Chronic pyelonephritis
  - Diabetes mellitus
  - Hypothyroidism

- Acquired RTA type II:
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Tubulointerstitial nephritis and interstitial fibrosis
  - Gordon syndrome
  - Sickle cell nephropathy

- Acquired RTA type III:
  - Fanconi syndrome due to toxin-related or hereditary tubular defects
  - Osteomalacia
  - Nephrolithiasis
  - Nephrocalcinosis

- Acquired RTA type IV:
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Tubulointerstitial nephritis and interstitial fibrosis

- Acquired RTA type V:
  - Sickle cell nephropathy

**ASSOCIATED CONDITIONS**

- Acquired RTA type I:  
  - Autoimmune disease: Systemic lupus erythematosus (SLE), Sjögren syndrome, primary biliary cirrhosis, chronic active hepatitis
  - Chronic pyelonephritis
  - Diabetes mellitus
  - Hypothyroidism

- Acquired RTA type II:  
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Tubulointerstitial nephritis and interstitial fibrosis
  - Gordon syndrome
  - Sickle cell nephropathy

- Acquired RTA type III:  
  - Fanconi syndrome due to toxin-related or hereditary tubular defects
  - Osteomalacia
  - Nephrolithiasis
  - Nephrocalcinosis

- Acquired RTA type IV:  
  - Tubulointerstitial nephropathies
  - Obstructive nephropathy
  - Tubulointerstitial nephritis and interstitial fibrosis
  - Gordon syndrome
  - Sickle cell nephropathy

- Acquired RTA type V:  
  - Sickle cell nephropathy

**PATHOLOGIC FINDINGS**

- Nephrolithiasis
- Nephrocalcinosis
- Osteomalacia

**IMAGING**

- Plain x-ray and computed tomography (CT) urogram:
  - Likely to demonstrate nephrocalcinosis and nephrolithiasis
DIFFERENTIAL DIAGNOSIS
- Other causes of metabolic acidosis (215C)
  - Lactic and ketoadidosis, chronic renal failure, chronic diarrhea, etc.
- Azotemia
- Bilateral stones
- Calcium phosphate stones
- Chronic pyelonephritis
- Hypochloremia < 0.5 mmol/L
- Hypokalemia
- Medullary nephrocalcinosis
- Medullary sponge kidney
- Recurrent stones: >2yr

TREATMENT
GENERAL MEASURES
- Identifiable causes, such as obstructive uropathy or drug-induced RTA, should be corrected or eliminated
- If there is no identifiable etiology, then direct treatment to correction of acidosis

MEDICATION
First Line
- Alkali therapy decreases stone formation and growth, prevents nephrocalcinosis, normalizes growth retardation in children, and corrects hypokalemia in most cases.
- Oral alkali therapy: In both type I and type II RTA with the goal of treatment to restore urinary citrate to high-normal levels, and not simply correct the metabolic acidosis (315C).
  - Sodium bicarbonate (17.7 mmol/L)
  - Bictra (1 mmol Na, 1 mmol citrate)
  - Polytra (1 mmol Na, 1 mmol K, 2 mmol citrate)
  - Type II RTA generally requires lifelong treatment:
    - 1–4 mmol/g of oral bicarbonate or citrate in 2–3 divided doses in adults (405C)
    - May require potassium supplementation for hypokalemia
  - Type II (proximal) RTA:
    - 5–20 mmol/g in 4–6 doses due to the severe bicarbonate wasting.
    - Adults with bicarbonate levels > 10 mmol/L and no evidence of bone disease may not require treatment.
    - Supplemental potassium, calcium, vitamin D, and phosphate may become necessary.
  - Type IV (proximal) RTA: directed toward correction of hypokalemia rather than acidosis
    - Dietary potassium restriction
    - Thiazide or loop diuretics
    - Mineralocorticoid replacement in cases of adrenal disease or hyporeninemia (Hydrocortisone 0.1 mg/d)

Second Line
FKA

SURGERY/OTHER PROCEDURES
- Management of stone by shock wave lithotripsy, ureteroscopy, percutaneous nephrolithotomy, and rarely, open surgery
- Management of obstructive uropathy

ADDITIONAL TREATMENT
Radiation Therapy
FKA

Additional Therapies
FKA

COMPLEMENTARY & ALTERNATIVE THERAPIES
FKA

ONGOING CARE

PROGNOSIS
- Primary RTAs: Although a permanent disease, prognosis is excellent if diagnosis and treatment initiated early.
- Prognosis of other RTAs depends on associated disease

COMPLICATIONS
- Hypercalciuria
- Hyperkalemia or hypokalemia
- Nephrocalcinosis
- Nephrolithiasis
- Osteomalacia/osteoporosis

FOLLOW-UP

Patient Monitoring
- Spot urine testing for NAG (<0.05 mmol/g of creatinine in adults).
- Spot urine calcium and citrate.
- Monitoring of serum ions and growth curves in children.
- Weekly monitoring of serum ions in adults.

Patient Resources
- National Kidney and Urologic Diseases Information Clearinghouse (NIDDK) http://kidney.nih.gov/koaidney/Pub/TubularAcidosis

REFERENCES

ADDITIONAL READING

- Nephrocalcinosis
- Osteopenia and Osteoporosis, Urologic Considerations
- Urolithiasis, Renal

CODES
ICD9
- 255.42 Mineralocorticoid deficiency
- 276.40 Hypokalemia
- 588.89 Other specified disorders resulting from impaired renal function

ICD10
- E87.40 Unspecified adrenocortical insufficiency
- E87.5 Hyperkalemia
- N26.89 Other disorders resulting from impaired renal tubular function

CLINICAL/SURGICAL PEARLS
- Type I RTA is the only type associated with increased stone formation, nephrocalcinosis.
- Potassium levels should be monitored during alkali therapy for RTA and replaced appropriately.
- A young person with multiple stones with systemic acidosis and high urine pH, a diagnosis of type I RTA should be considered.
RENAL VEIN THROMBOSIS, ADULT AND PEDIATRIC
Adonteng A. Kivakye, MD

BASICS
DESCRIPTION
• Renal vein thrombosis (RVT) is an acute or chronic thrombosis in the renal vein leading to a reduction in venous drainage of the kidney.
• In infants, RVT typically presents as a severe illness, occasionally with shock.
• Asynchronous events are: 60% have enlarged kidneys on physical exam; gross hematuria and microangiopathic hemolytic anemia and thrombocytopenia can also be present.
• In the adult, RVT presentation depends on onset of RVT:
  • Acute RVT: Triad of sudden flank pain
  • Costovertebral angle tenderness
  • Gross hematuria
• Chronic RVT: Generally asymptomatic.
• Can have proteinuria and microscopic or gross hematuria.
EPIDEMIOLOGY
Incidence
• Neonates and infants:
  • Commonly associated with hypoglycaemia, dehydration, shock, and/or sepsis
  • Usually acute and unilateral; more common on the left side; although 30% bilateral
  • Male-to-female ratio 3:1
  • Accounts for approximately 10% of venous thrombosis in newborns
  • Most common form of thrombosis not associated with a vascular catheter
• Adults:
  • Associated with nephrotic syndrome
  • Reported incidence of RVT in patients with nephrotic syndrome ranges from 6–62%.
  • Nephrotic syndrome, renal vein thrombosis
  • More often chronic and unilateral

Prevalence
N/A
RISK FACTORS
• Neonates/infants:
  • Acute hypoglycaemia
  • Birth trauma
  • Genetics
• Adults:
  • Abdominal tumor, especially renal cell carcinoma
  • Insulin/hyperglycaemia
  • Intrinsinc hypercoagulability (eg, Factor V Leiden deficiency)
  • Nephrotic syndrome
  • Membranous nephropathy
  • Leukemia
  • Acute leukemic crisis
  • Neoplastic disease
  • Use of oral contraceptives, steroids
  • Contraceptive use
  • Membranous nephropathy
  • Intrinsic hypercoagulability (eg, Factor V Leiden deficiency)
  • Hemolytic anemia
  • Nephrotic syndrome
  • Preterminal course

PATHOPHYSIOLOGY
• Newborn/infant:
  • Diminished intravascular blood flow due to hypovolemia (sufficient dehydration, diarrhea)
  • Causes prothrombotic state
  • Oliguria
  • Marked elevation in LDH with normal transaminases
• Adult:
  • Abdominal tumor, especially renal cell carcinoma
  • Nephrotic syndrome
  • Use of oral contraceptives, steroids
  • Hypothyroidism
  • Pregnancy
  • Pregnancy
  • Pregnancy
  • Pregnancy

ASSOCIATED CONDITIONS
• DVT in patients with nephrotic syndrome
  • Pulmonary embolus

GENERAL PREVENTION
• Adults: Long-term anticoagulation is appropriate if RVT has recurred when patients discontinued anticoagulation.

DIAGNOSIS
HISTORY
• Newborn/infant:
  • Stenotic or bilateral, flank masses
  • Evidence of dehydration
  • Evidence of early postnatal course
  • Dehydration
  • Gross hematuria
  • Microangiopathic hemolytic anemia
  • Nephrotic syndrome

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Newborn/infant:
  • Hemolytic anemia
  • Hypothyroidism
  • Pregnancy
  • Pregnancy
  • Pregnancy
  • Pregnancy

Imaging
• Newborn/infant:
  • Ultrasound, Doppler
  • Abdominal ultrasound

RENAL VEIN THROMBOSIS, ADULT AND PEDIATRIC
Adonteng A. Kivakye, MD

436
Adult:  
- Inferior vena cavaography with selective catheterization of the renal vein is the gold standard for the diagnosis.  
- CT findings are similar in noninvasive evaluation of acute RVT.  
- Sensitivity of CT angiography approaches 100%; considered current imaging modality of choice  
- Low attenuation within the renal veins proximal venous enlargement  
- Capular venous collaterals, thickened Gerota’s fascia and pericapsular streaking  
- Doppler ultrasonography is helpful, especially in a transplanted kidney.  
- MRI: Excellent imaging, avoids iodinated contrast, but concerns with radiation in patients with renal insufficiency  
- IOP  
- faint or absent excretion of contrast  
- Enlarged kidney due to congestion  
- Collateral circulation may cause collecting system obstruction and/or twisting of ureter  
- Renal pelvic is often distorted

Pathologic Findings:  
- Membranous nephropathy is the most common finding in the setting of nephrotic syndrome and RVT confirms etiology and may guide therapy

TREATMENT  

GENERAL MEASURES  
- Evaluate and treat all underlying causes  
- Aggressive hydration and treatment of septic, diuretic, and electrolyte abnormalities

MEDICATION  

First Line  
- Newborn/Infant:  
  - Use of thrombolytic agents is reported, but controversial  
  - Systemic heparization:  
    - Prevents thrombus propagation into vena cava (risk of propagation low with fluid and electrolyte repletion)  
    - Used in neonates with bilateral RVT

Second Line  
- Heparin

SURGERY/OTHER PROCEDURES  
- Infants: no role for surgical thrombectomy  
- Thrombectomy in adults:  
  - Rarely used, because neither renal preservation nor improvement in survival demonstrated  
  - Surgical thrombectomy (either open or percutaneous) in patients with acute bilateral RVT with poor prognosis  
  - Percutaneous post-thrombolytic RVT  
  - Nephrectomy in highly selected patients for blurring measures  
  - Radical nephrectomy and thrombectomy in renal cell carcinoma

ADDITIONAL TREATMENT  
- Infants with renal failure—dialysis if needed  
- RVT filters are indicated in high-risk adult patients for pulmonary embolism.

Radiation Therapy
- N/A

Additional Therapies
- Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS  
- Neonates: Mortality rate of 3%  
- The kidney may recover completely, atrophy, or remain enlarged due to congestion  
- The kidney may recover completely, atrophy, or remain enlarged due to congestion

COMPlications (S)  
- Consumptive coagulopathy  
- Pulmonary embolism  
- Renal failure  
- Loss of graft in transplant patient

FOLLOW-UP  

Patient Monitoring  
- Neonates/Infant:  
  - Renal function may be followed using nuclear scanning. Atrophy is often detected long term. About 5% of affected neonates progress to diastasis or transplantation.  
  - Monitor blood pressure, as renovascular hypertension may occur after RVT in ~20%, even with normal renal function.  
- Adult:  
  - Treat cause of nephrotic syndrome  
  - Long-term anticoagulation as preventive measure in nephrotic syndrome not supported  
- Because RVT may be asymptomatic, all patients with nephrotic syndrome should be monitored for symptoms of RVT

Patient Resources

- Renal Cell Carcinoma with Tumor Thrombus  
- Renal Vein Thrombosis, Adult and Pediatric Image  
- Renal Vein, Lymphangioma

ICD9  
- 406.3 Other venous embolism and thrombosis of renal vein  
- 581.9 Nephrotic syndrome with unspecified pathologic lesion in kidney  
- 788.0 Renal colic

ICD10  
- R32.8 Embolism and thrombosis of renal vein  
- N04.9 Nephrotic syndrome with unspecified morphologic changes  
- N23 Unspecified renal colic

CLINICAL/SURGICAL PEARLS  
- Renal vein thrombosis (RVT) is associated with nephrotic syndrome in adults.  
- Membranous nephropathy is most common pathology in RVT with nephrotic syndrome.  
- Neonates and infants more likely than adults to have bilateral RVT.
Retrograde Ejaculation
Pravin K. Rao, MD

PATHOPHYSIOLOGY

- Normal ejaculation requires:
  - Central control in multiple brain regions
  - Sympathetic (T12–L3):
    - Contract bladder neck, seminal vesicles, ejaculatory ducts
  - Parasympathetic (S2–S4):
    - Contract ischiocavernosus
  - Dorsal nerve of penis

- Neurologic control:
  - Sensory (S2–S4):
    - Pelvic nerve
  - Motor (S2–S4):
    - Efferents from sacral cord
  - Sympathetic (T12–L3):
    - Hypepogastric nerves
  - Neural disruption:
    - Spinal cord injury (SCI)
    - Diabetes mellitus (DM)
  - Medication side effects
    - Selective serotonin reuptake inhibitors

ASSOCIATED CONDITIONS

- Idiopathic
- Neurotrophic
- Medication side effects
- Selective serotonin reuptake inhibitors

PATHOLOGY

- Normal ejaculate:
  - Seminal vesicles
  - Prostate
  - Vas deferens

DIAGNOSIS

HISTORY

- Presence of erectile dysfunction
- Cloudy urine after sex
- Symptoms of hypogonadism
- Medical history
- Symptoms of retrograde ejaculation
- Medication side effects
- History of Mendelian conditions

DIAGNOSTIC TESTS & INTERPRETATION

LAB

- Normal ejaculate:
  - Seminal vesicles
  - Prostate
  - Vas deferens

PHYSICAL EXAM

- Normal physical exam:
  - Absent ejaculation

DIAGNOSTIC PROCEDURES/SURGERY

- Retrograde ejaculation:
  - Bladder neck closure
  - Prostate volume
  - Vicarious semen

IMAGING

- Retrograde ejaculation:
  - Bladder neck closure
  - Prostate volume

Pathologic Findings

Pharmacologic Findings
RETROGRADE EJACULATION

DIFFERENTIAL DIAGNOSIS
- Anejaculation
- Anorgasmia (inability to reach orgasm)
- Aspermia due to failure of emission
- Congenital bilateral/lateral absence of the vas deferens
- ED
- Erectile dysfunction
- Failure to reach orgasm
- Poor expulsion of ejaculate through flaccid penile urethra
- Hypogonadism
- Semen spillage in lab
- Poor semen collection technique

TREATMENT
GENERAL MEASURES
- Treatment typically reserved for fertility purposes
- Treat reversible causes
- Modify causative medications
  - Change or discontinue causative medications
  - Some clinicians favor alfuzosin for BPH (possibly less RE than other α-blockers)

MEDICATION
First Line
- α-adrenergic agents
  - Dosing structure highly variable:
    ◦ Pseudoephedrine 60 mg
    ◦ Ephedrine 25–50 mg
    ◦ Imipramine 25–50 mg (may cause dizziness and nausea)
  - Frequency ranges from QD to QID
  - Duration ranges from 2–14 days
  - Side effects: HTN, tachycardia
- Author recommendation: Pseudoephedrine 60 mg QID × 2–7 days prior to ejaculation (titrate to effectiveness)
- Medical therapy less likely to be effective after bladder neck injury or surgery

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Spinal fluid leakage
  - For use with assisted reproductive techniques
  - IVF (in vitro fertilization)
  - ICSI (intracytoplasmic sperm injection)

ADDITIONAL TREATMENT
- Radiation Therapy
- Additional Therapies
- N/A
- Complementary & Alternative Therapies
- N/A

ONGOING CARE
- Patient Monitoring
  - Follow-up semen analysis to determine effectiveness of medical therapy
- Patient Resources
  - MedlinePlus: Retrograde Ejaculation

CODES
- ICD9
  - 355.9 Mononeuritis of unspecified site
  - 608.87 Retrograde ejaculation
  - 606.9 Male infertility, unspecified

- ICD10
  - G62.9 Polyneuropathy, unspecified
  - G64.6 Other male infertility
  - N55.14 Retrograde ejaculation

CLINICAL/SURGICAL PEARLS
- In men with spinal cord injury (SCI) or history of retroperitoneal surgery, men may have failure of seminal emission, so sperm retrieval from the bladder may not be feasible.
**PATHOPHYSIOLOGY**

- **Secondary infection if spread is from infected adjacent organs (78% enteric bacteria).**
- **Most common source from renal diseases accounting for 47% of retroperitoneal abscesses.**
- **Infection seeds a contained space in retroperitoneum:**
  - Depending on the source, aerobic and anaerobic organisms may be present.
  - **Usual source:** normal flora from a nearby organ site (eg, GI, GU, female reproductive tract).
  - **Multimicrobial infections are common.**
  - **Malignancy:** frequently violates fascial barriers, whereas abscesses tend to be contained by the fascia.
  - **Hypoxia and lack of appropriate blood supply limit effective immune response.**
  - **If untreated, bacteremia, followed by shock ensues.**
  - **TB and Staphylococcus (skin source) were previously major pathogens, but are less common today.**
  - **Proteus and Escherichia coli are the most commonly cultured bacteria in retroperitoneal abscesses.**
  - **Common pathogens (aerobic and anaerobic):**
    - Enterobacteriaceae
    - E. coli
    - Klebsiella pneumoniae
    - Proteus spp.
    - Pseudomonas aeruginosa
    - Anaerobes:
      - Peptostreptococcus sp.
      - Bacteroides fragilis
      - Prevotella sp.
      - Clostridium sp.
      - Enterococcus sp.
      - Streptococcus sp.
      - S. aureus
    - **Site-specific pathogens:**
      - Pancreatic abscess:
        - E. coli
      - K. pneumonia
      - F. necrophorum
      - Peptococcus sp.
      - Streptococcus sp.
      - **Anterior retroperitoneal:**
        - F. nucleatum
      - **S. aureus**
  - **Unlike peritoneal cavity, retroperitoneum is relatively avascular:**
    - **Usual source:** normal flora from a nearby organ site.
    - **Virulence factors:** Mucoid substances and capsule enhance spread.
  - **Common retroperitoneal abscesses:**
    - Pancreatic abscess
    - Retroperitoneal abscess
    - **Common sites:**
      - **Prevesical, retrovesical, presacral, perirectal**
      - **Pelvic retroperitoneal:**
      - **Retrofascial (aka iliopsoas):**
      - **Posterior retroperitoneum (aka epidural):**
      - **Anterior retroperitoneum:**
      - **Pancreatic abscess:**
      - **Fusobacterium nucleatum**

**ASSOCIATED CONDITIONS**

- **Diabetes, liver disease, renal insufficiency, immunosuppression, retroperitoneal hematoma:**
- **GU specific:** Urinary tract infection (UTI), urethral stenosis, instrumentation/surgery, malignancy
- **GI specific:** Malignancy, surgery, paraneoplastic pathologies

**GENERAL PREVENTION**

Perioperative antibiotic prophylaxis

**DIAGNOSIS**

- **Abdominal or flank pain (60–75%)**
- **Swelling, fever, and chills (30–90%)**
- **Malaise (15–30%)**
- **Nausea/vomiting**
- **Anorexia**
- **Weight loss (12%)**
- **Duration of symptoms is typically longer than 1 wk**
- **Recent instrumentation/surgery/truma**
- **Recent treatment for UTI**
- **History of urolithiasis, inflammatory bowel disease, pancreatitis, diverticulitis, appendicitis, osteomyelitis, malignancy, TB**
- **Medical comorbidities:** Diabetes, renal insufficiency, immunosuppression (ie, HIV)

**PHYSICAL EXAM**

- **General vital signs:**
  - Fever
  - Tachypnea
  - Tachycardia
  - Tachycardia
- **Unlike peritoneal cavity, retroperitoneum is relatively concealed on exam.**
  - **Assess for:***
    - Tenderness: Usually localized, dull, and mild
    - Costovertebral angle tenderness
    - **Palpable flank/abdominal mass:**
      - Lower abdominal, groin, and/or upper thigh
      - **Retroperitoneal abscess:**
        - Flank pain/abdominal mass
        - Lower abdominal, groin, and/or upper thigh
        - **Referred pain due to irritation of retroperitoneal nerves:**
      - **Fossa sign:** Increased pain when flexing patient’s thigh against examiner’s hand; suggests involvement of psoas muscle

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Lab:**
  - Findings often nonspecific (ie, elevated ESR)
  - Obtain CBC (leukocytosis)
  - **BNP:** Serum glucose often elevated
- **Imaging:**
  - **Approximately 30% will have microscopic hematuria.**
  - **Pyuria is also very common.**
- **Urine/blood cultures:**
  - Evaluates surrounding organs (ie, possible sources)

**IMAGING**

- **Cross-sectional CT or MRI is most helpful:**
  - **CT (100% sensitivity, 77% specificity):**
  - **Low-density mass in retroperitoneum with surrounding inflammation**
  - **Gas may be present in approximately 33% of cases.**
  - **Evaluates surrounding organs (ie, possible sources).**

**DIAGNOSIS**

- **Abdominal or flank pain (60–75%)**
- **Swelling, fever, and chills (30–90%)**
- **Malaise (15–20%)**
- **Nausea/vomiting**
- **Anorexia**
- **Weight loss (12%)**
- **Duration of symptoms is typically longer than 1 wk**
- **Recent instrumentation/surgery/truma**
- **Recent treatment for UTI**
- **History of urolithiasis, inflammatory bowel disease, pancreatitis, diverticulitis, appendicitis, osteomyelitis, malignancy, TB**
- **Medical comorbidities:** Diabetes, renal insufficiency, immunosuppression (ie, HIV)

**PHYSICAL EXAM**

- **General vital signs:**
  - Fever
  - Tachypnea
  - Tachycardia
  - Tachycardia
- **Unlike peritoneal cavity, retroperitoneum is relatively concealed on exam.**
  - **Assess for:**
    - Tenderness: Usually localized, dull, and mild
    - Costovertebral angle tenderness
    - **Palpable flank/abdominal mass:**
      - Lower abdominal, groin, and/or upper thigh
      - **Retroperitoneal abscess:**
        - Flank pain/abdominal mass
        - Lower abdominal, groin, and/or upper thigh
        - **Referred pain due to irritation of retroperitoneal nerves:**
      - **Fossa sign:** Increased pain when flexing patient’s thigh against examiner’s hand; suggests involvement of psoas muscle

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Lab:**
  - Findings often nonspecific (ie, elevated ESR)
  - Obtain CBC (leukocytosis)
  - **BNP:** Serum glucose often elevated
- **Imaging:**
  - **Approximately 30% will have microscopic hematuria.**
  - **Pyuria is also very common.**
- **Urine/blood cultures:**
  - Evaluates surrounding organs (ie, possible sources)

**IMAGING**

- **Cross-sectional CT or MRI is most helpful:**
  - **CT (100% sensitivity, 77% specificity):**
  - **Low-density mass in retroperitoneum with surrounding inflammation**
  - **Gas may be present in approximately 33% of cases.**
  - **Evaluates surrounding organs (ie, possible sources).**
**RETROPERITONEAL ABSCESS**

**SURGERY/OTHER PROCEDURES**
- Early percutaneous drainage (if)
  - Essential in lesions >3 cm
  - May consider antibiotics only in abscesses <3 cm
- Surgical drainage must be considered if:
  - Safe percutaneous drainage not possible
  - Perinephric/perirenal abscess
  - Ruptured aortic aneurysm
  - TB
  - Ruptured viscus (ie, duodenal ulcer)
  - Pancreatitis
  - Osteomyelitis
  - Necrotizing fasciitis
  - Malignancy
  - Consider sending for AFB culture

**Diagnosis**
- Tailor duration of treatment to clinical progress
- Refine antibiotic coverage based on culture results
- Metronidazole (4)

**Pathologic Findings**
- Nonspecific signs and symptoms frequently lead to a delay in diagnosis and treatment.
- Obtain cultures
- Avoid multi-loculated abscesses
- Percutaneous drainage has failed
- Safe percutaneous drainage not possible
- May not show calcifications or gas collections
- Edema in surrounding fat seen as high signal on T2-weighted images
- May not show psoas muscle, fistulization to the skin
- Essential in lesions >3 cm
- Percutaneous drainage has failed
- Multiloculated abscesses
- Perinephric/perirenal abscess
- Perforated viscus (ie, duodenal ulcer)
- Pancreatitis
- Osteomyelitis
- Necrotizing fasciitis
- Malignancy

**Prognosis**
- Mortality is considerable (5–50%) despite modern management that combines antibiotics, drainage, and intensive care support.
- High success with antibiotics and percutaneous drainage (>80%)
- Only 1–4% recurrence with percutaneous drainage
- If abscess is not drained and only antibiotics are used, mortality approaches 100%

**Complications**
- Abscess crossing the midline to opposite side or tracking into the ipsilateral thigh
- DVF
- GI bleed
- Organ failure
- Pneumonia
- Secondary infections: Osteomyelitis, involvement of major muscle, fatalization to the skin

**Follow-Up**
- Patient Monitoring
  - Repeat imaging
  - CT or MRI (if MRSA, clostridial)
  - Timing depends on clinical progress
  - Discharge
  - Must be monitored carefully and irrigated appropriately
  - Can be removed when:
    - Patient is clinically improved
    - Drainage stops (>10 mL/d) or becomes serous
    - Abscess cavity involutes is documented on imaging

**Patient Resources**
- N/A

Retroperitoneal Fibrosis (RPF, Ormond Disease)

Leonard G. Gomella, MD, FACS

BASICS

PATHOPHYSIOLOGY

Mechanical obstruction of the ureters is usual

HALLMARK IS MEDIAL DEVIATION OF THE URETERS ON IMAGING WITH OR WITHOUT HYDROPEEJYSIS.

Epidemiology

Incidence

- In Finland, incidence is 0.1-1,000/yr
- Unknown, but estimated at 1.200,000-1,500,000/yr

Prevalence

1:18 per 100,000

Risk Factors

- Adverse exposure
- Associated with autoimmune disorders
- Abdominal artery aneurysm
- Male > female (2:1:1)
- RPF most common in the 5th-6th decades, but can occur at any age
- Use of implicated medications (see below)
- Malignancy

Genetics

- Evidence supports an immunogenic role with certain HLA alleles:
  - HLA-DRB1*04 and HLA-B8*08

PATHOPHYSIOLOGY

- Idiopathic RPF recently identified as a retromesenteric disease (6,4 related disease IgG4-RD)
- And is a multisystem, fibroinflammatory condition
- Most commonly, the retroperitoneal thickening is located between L2 and T1, close to the aortic bifurcation
- Mechanical obstruction of the ureters is usual presentation; may also cause venous or arterial occlusion
- Primary RPF
  - 70% of cases are idiopathic, and the exact etiology is unknown
- Mitchell and Parises classify idiopathic RPF in a range of diseases collectively termed chronic pancreatitis
  - Immune-mediated reaction to antigens (cereal and low-density lipoprotein) within autoimmune pancreatitis
  - Often have autoantibodies, and thus overlap with the pathogenesis of RPF

- Secondary RPF: 30% of patients with RPF have an identifiable cause of their RPF:
  - Medications:
    - Prolonged therapy with ergot alkaloids such as methylergometrine (once widely used for migraine headaches)
    - Others include LSD, methyldopa, phenacetin, pht-blockers, amphetamines, hydralazine, and anticoagulants
  - Malignancy:
    - Longest (most common), multiple myeloma, carcinoma, pancreatic tumor, prostate cancer, testicular tumor, and sarcoma
  - Radiotherapy for malignancies such as seminoma, colon, or pancreatic cancer
  - Infections:
    - Tuberculosis, actinomycosis, histoplasmosis
  - Others: Trauma (hemorrhage, urinary extravasation), surgical injury

Diagnosis

- Presentation may include sclerosing mediastinitis, scarring of the kidneys, orbital pseudotumor, and myositis

Associated Conditions

- Atherosclerotic disease (abdominal aortic aneurysm)
- Celiac disease
- Arthritis (rheumatoid arthritis)
- Bronchiectasis
- Sclerosing cholangitis
- Orbital pseudotumor
- Periarteritis nodosa
- Immunoglobulin G4-related disease (IgG4-RD) and autoimmune polyglandular syndrome
- Certain HLA haplotypes:
  - HLA-DRB1*04
- Polygenetic genetic risk

Diagnosis

- A positive family history of autoimmune disease
- Autoimmune markers
- History of smoking
- Use of ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Medication history especially ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Infections
  - Tuberculosis, actinomycosis, histoplasmosis
- Malignancy:
  - Presentation may include sclerosing mediastinitis, scarring of the kidneys, orbital pseudotumor, and myositis

Associated Conditions

- Atherosclerotic disease (abdominal aortic aneurysm)
- Celiac disease
- Arthritis (rheumatoid arthritis)
- Bronchiectasis
- Sclerosing cholangitis
- Orbital pseudotumor
- Periarteritis nodosa
- Immunoglobulin G4-related disease (IgG4-RD) and autoimmune polyglandular syndrome
- Certain HLA haplotypes:
  - HLA-DRB1*04
- Polygenetic genetic risk

Diagnosis

- A positive family history of autoimmune disease
- Autoimmune markers
- History of smoking
- Use of ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Medication history especially ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Infections
  - Tuberculosis, actinomycosis, histoplasmosis
- Malignancy:
  - Presentation may include sclerosing mediastinitis, scarring of the kidneys, orbital pseudotumor, and myositis

Associated Conditions

- Atherosclerotic disease (abdominal aortic aneurysm)
- Celiac disease
- Arthritis (rheumatoid arthritis)
- Bronchiectasis
- Sclerosing cholangitis
- Orbital pseudotumor
- Periarteritis nodosa
- Immunoglobulin G4-related disease (IgG4-RD) and autoimmune polyglandular syndrome
- Certain HLA haplotypes:
  - HLA-DRB1*04
- Polygenetic genetic risk

Diagnosis

- A positive family history of autoimmune disease
- Autoimmune markers
- History of smoking
- Use of ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Medication history especially ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Infections
  - Tuberculosis, actinomycosis, histoplasmosis
- Malignancy:
  - Presentation may include sclerosing mediastinitis, scarring of the kidneys, orbital pseudotumor, and myositis

Associated Conditions

- Atherosclerotic disease (abdominal aortic aneurysm)
- Celiac disease
- Arthritis (rheumatoid arthritis)
- Bronchiectasis
- Sclerosing cholangitis
- Orbital pseudotumor
- Periarteritis nodosa
- Immunoglobulin G4-related disease (IgG4-RD) and autoimmune polyglandular syndrome
- Certain HLA haplotypes:
  - HLA-DRB1*04
- Polygenetic genetic risk

Diagnosis

- A positive family history of autoimmune disease
- Autoimmune markers
- History of smoking
- Use of ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Medication history especially ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular disorders
- Infections
  - Tuberculosis, actinomycosis, histoplasmosis
- Malignancy:
  - Presentation may include sclerosing mediastinitis, scarring of the kidneys, orbital pseudotumor, and myositis

Diagnostic Procedures/Surgery

- Retroperitoneal biopsy may be indicated in patients with severe azotemia prohibiting the use of contrast-enhanced imaging. Usually shows medial deviation of ureters.
- CT-guided biopsy may be necessary to rule out a malignant process.
Pathologic Findings
- Gross findings secondary RPF:
  - Smooth, flat, firm, grayish-tan-colored mass
- Extends from the origin of the renal vessels to the distal extent of the common iliac vessels
- May also involve the thoricacic aorta and other arterial areas
- Microscopic findings: Collagen bundles with capillary proliferation and inflammatory cells
- Later xanthomatous and vascular mass with sheets of hyscocellular collagen
- Vacuoles of small retroperitoneal vessels with plasma cells staining for IgG (polyclonal IgG subclass)

DIFFERENTIAL DIAGNOSIS
- Medial deviation of the ureters
  - Malignancies, aneurysms, bladder diverticulum, and prior surgery
  - 20% of normal individuals have medial deviation of the ureters, especially on the right
- Retroperitoneal mass: See also Section I
  - "Retroperitoneal masses, fluid, and cysts"
  - Malignant processes, inflammatory xerophibrotic tumors
  - Declined type fibromatoses, associated with osteal syndrome
  - Presents as soft tissue mass with mass effect

TREATMENT
- Discontinue any offending medications
- Relieve urinary obstruction:
  - Monitor for postobstructive diuresis after the urinary system is decompressed
- Biopsy to rule out malignancy
- C.I.L.
  - If clear, discontinuation of steroids
  - Immediate ureterolysis may also be helpful:
    - Immunosuppressive agents (e.g., cyclophosphamide or azathioprine for 6–12 mo)
      - Prednisone 60 mg every other day for 2 mo, then tapered over the next 2–3 mo to 10 mg/d for a total of 1 yr
      - Tapered over 5 mo to 5 mg/d
- Observation:
  - May be a role in patients on methylsergide after discontinuation of the medication if normal renal function.
  - These patients should be monitored for resolution of hydronephrosis. If the hydronephrosis does not resolve, then the standard combination of medical and surgical therapy should be administered.
- Tenofovir has been used;
- Low-protein, sodium-restricted diet

Ongoing Care
PROGNOSIS
- Prognosis is excellent with combined medical and surgical therapy.

COMPLICATIONS
- Recurrence of RPF:
  - Typically in the 1st yr, usually limited to those treated with medical therapy
  - Urinary injury, requiring further surgical management
  - Vascular injury
  - Postoperative adhesions due to peritoneal irritation

FOLLOW-UP
- Patient Monitoring:
  - Patients can be monitored at regular intervals with symptom check, ESR/CRP levels, creatinine, and degree of hydronephrosis on US
  - CT/MR is usually performed 2–4 mo after the beginning of the steroid treatment (1)
- Patients treated with definitive surgical intervention require less frequent follow-up

Patient Resources
- Medline Plus: Retroperitoneal Fibrosis

REFERENCES

ADDITIONAL READING

CODES
- ICD9
  - 590.80 Pyelonephritis, unspecified
- 590.90 Pyelonephritis, unspecified (diabetes mellitus, medical) (590.90 diabetes mellitus, unspecified)
- 599.60 Urinary obstruction, unspecified
- 599.60 Urinary obstruction, unspecified

CLINICAL/SURGICAL PEARLS
- Although no tests are diagnostic of RPF, most will present with medid deviation of the ureters on imaging.
  - CT is the image modality of choice
  - Stents are often placed for relief of obstruction
  - Patients who fail steroid treatment without evidence of malignancy should undergo ureterolysis.
Retroperitoneal Masses, Fluid, and Cysts

Mark R. Anderson, MD, MSc
Judd W. Moul, MD, FACS

Description

Retroperitoneal masses and cysts can originate from retroperitoneal organs or nonorgan tissue. The latter are relatively rare.

- 70–80% of primary retroperitoneal neoplasms are malignant in nature, and these account for 0.1–0.2% of all malignancies in the body.
- Most cystic lesions within the retroperitoneum are benign; unless the lesion is mostly solid then suspect malignancy.
- Metastatic disease is the most common etiology of a solid retroperitoneal mass.
- Liposarcomas are among the most common of primary retroperitoneal tumors and are distinguished by their large dimensions and range of subtypes.

Prevalence

N/A

Risk Factors

Primary, solid cystic retroperitoneal mass: Previous radiotherapy (dose dependent), chemical exposure (lynyd chlorite, arsenic), HIV/AIDS

Primary, cystic retroperitoneal mass: Parasitic infection, embryonic remnants, prior lymphadenectomy

Genetics

- Tubulenc sclerosis (TSC), 75 mutation, tumor suppressor loss
- Werner syndrome (chromosome 8 alteration, premature aging)
- Li–Fraumeni syndrome (p53 mutation, tumor suppressor loss)
- Neurofibromatosis (NF1, NF2 mutation)

Malignant neoplasms are being reclassified based on a molecular basis. Well-differentiated and de-differentiated lesions are a continuum of lesions based on the genetic abnormality of giant and ring chromosomes usually involving chromosome 12.

Gene amplification, particularly of \( MDM2 \), chromosomes usually involving chromosome 12.

Pathophysiology

- The retroperitoneum extends from the diaphragm superiorly to the pelvis inferiorly and is situated between the posterior parietal peritoneum anteriorly and the transversalis fascia posteriorly. (1)
- The anterior pararenal space is bordered anteriorly by the posterior parietal peritoneum, posteriorly by the anterior renal fascia (Gerota fascia), and laterally by the posterior parietal peritoneum and transversus fascia. (1)
- The perirenal space is situated within the anterior renal fascia (Gerota fascia) and the transversalis fascia. 
- The great vessel space is the fat-containing region that surrounds the aorta and the inferior vena cava (IVC) and lies anterior to the vertebral bodies and psoas muscles.
- Below the kidneys, the anterior and posterior pararenal spaces merge to form the infrarenal retroperitoneal space, which communicates inferiorly with the presacral space and extraperitoneal compartments of the pelvis. 
- Due to the loose connective tissue in the retroperitoneum, tumors can have widespread growth and extension before clinical presentation.

Associated Conditions

N/A

General Prevention

N/A

Diagnosis

History

- Headaches, palpitations, etc. for hypertension
- Unexplained weight loss
- Constitutional symptoms
- Night sweats
- History of chemotherapy, radiation therapy
- Back or bone pain
- Abdominal swelling
- Malignant: Metastases, methylenetetrahydrofolate, L150Q, p16, p14, p10, p9, p8, p7, p6, p5, p4, p3, p2, p1, p0
- Sporadic gastrointestinal stromal tumor activating kinase mutations KIT or PDGFRA

Physical Exam

- Vital signs for hypertension
- Carnes
- Lymphadenopathy
- Neurologic deficits from paraneoplastic syndrome
- Lower extremity lymphedema
- Breast exam
- Neurologic exam
- Testicular exam
- Abdominal mass
- Signs of visualization

Diagnostic Tests & Interpretation

- CBC: Lactate dehydrogenase (infection or lymphoma), leukopenia, anemia
- Serum chemistry: Elevated serum creatinine, azotemia (obstructive uropathy), transaminisms (biliary obstruction), and elevated alkaline phosphatase (bone involvement).
- AFP, L-MY, p-HCG: Testicular tumor markers
- EBL: Elevated in retropertioneal infection
- U MR: Hematuria, pyuria
- Urology: Evidence of a malignant urothelial source
- Blood and urine culture
- Adrenal mass: Phaeochromocytoma screen
- CT urogram for RCC and urothelial carcinoma
- CT can show enhancement, fat density, water density to help characterize underlying components
- MRI better at defining local invasion
- Ultrasonound can differentiate between solid and fluid-filled masses but not good at determining malignant potential or regional mets
- CT with contrast has relative contraindication if GFR <60, MRI has relative contraindication if GFR <30.
- NAG-3 dimeric renal scan can determine relative differential function between each kidney and urine obstruction.
- CT urogram for mass
- Bone scan, mammogram if needed
- Cytocentrifuge pelvic/prostatic

Diagnostic Procedures/Surgery

- Image-guided biopsy: CT or US-guided fine-needle aspiration is usually feasible, but core-needle biopsy improves diagnostic capability
- Open surgical biopsy (first option if the mass is small and inconvenienced located for needle biopsy
- Be prepared to complete the resection if carcinoma identified
- Aspiration of cyst: Fluid for cytology, culture, creatine
- Angiogram: To delineate relationship of tumor to vascular anatomy or to determine extent of aneurysm

444
Pathologic Findings
- Metastatic pathology is consistent with primary tumor pathology.
- Determination of benign vs. malignant tissue is not always possible, leaving final determination to the surgical pathology.
- Well-differentiated liposarcomas mostly resemble lipomas and are typically low grade.
- Rhabdomyosarcomas comprise 10–15% defined as high-grade malignant variants with very bizarre nuclei and huge lipoblasts and carry poor prognosis.
- Liposarcoma is most common (35%), followed by malignant fibrous histiocytoma (20%), rhabdomyosarcoma, and peripheral nerve neoplasm.
- Hemangioma: Diffuse, monomorphous proliferation of capillaries.
- Lymphangioma
- Pancreatic cyst and pseudocyst
- Lymphocele
- Urinoma
- Hematoma
- Cystic teratoma
- Mesothelioma
- Malignant lymphoma, extramedullary
- Germ cell tumors; choriocarcinoma, malignant teratoma, dysgerminoma, seminoma, nonseminoma germ cell tumors
- Paraganglioma, pheochromocytoma
- Schwannoma, neurofibroma
- Rhabdomyosarcoma, ganglioneuroblastoma (neuroblastoma)
- Chordoma
- Myxoma (myxosarcoma)
- Perivascular epithelioid cell tumor (PECT)
- Pleomorphic adenoma
- Hemangioma (angiosarcoma)
- Lipoma (liposarcoma)
- Angiomyolipoma, lymphangioleiomyomatosis, von Hippel-Lindau syndrome
- Myxofibrosarcoma (malignant fibrous histiocytoma)
- Giant cell tumor of tendon sheath
- Hackney's tumor (bizarre giant cell tumor)
- Carcinosarcoma
- Postoperative seroma

TREATMENT

GENERAL MEASURES
- Need tissue diagnosis via primary excision or needle biopsy
- Core biopsy better than fine needle if possible

PROGNOSIS
- RCC has good prognosis though is most lethal GU tumor
- Pheochromocytoma has good prognosis.
- Adrenal carcinoma typically presents late stage and has poor prognosis even with complete resection.
- Poorly differentiated (liposarcoma metastasize.)
- Complexly reacted, nonmetastatic, and low-grade sarcomas are associated with improved survival.
- Liposarcoma is an independent predictor of poor outcome.
- Adrenal carcinoma typically presents late stage and has poor prognosis even with complete resection.
- Hemangioma has good prognosis.
- RCC has good prognosis though is most lethal GU cancer and present with mets ~25% of time.

COMPLICATIONS
- Bleed injury
- Adenocarcinoma (liver, spleen, pancreas)
- Lymphocele
- Deep vein thrombosis
- Wound infection
- Transfusion-dependent anemia

FOLLOW-UP

Patient Monitoring
- Schedule imaging that is intensive during 1st 2 yr (q3–6mo) followed by biannual, migrating to annual by year 5 is generally recommended for most retroperitoneal masses.

Patient Resources
- N/A

  - C66.8 Other disorders of retroperitoneum

CLINICAL/SURGICAL PEARLS
- Most solid retroperitoneal masses are malignant.
RHYTHMOLYSIS
Sanjay S. Kasturi, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION
Rhabdomyolysis is muscle necrosis resulting in the egress of cellular muscle particles (mainly myoglobin, calcium, creatine kinase [CK], and lactic acid dehydrogenase [LDH]) into the blood stream.

In particular, myoglobin is harmful to the kidney and often causes acute kidney injury:

– Up to 15% of patients who have rhabdomyolysis can have renal failure.

There are many causes for rhabdomyolysis; this section primarily focuses on operative causes.

EPIDEMIOLOGY

– 2,600 cases per year (likely underreported)

Overall incidence of 0–4.9% in the laparoscopic nephrectomy data

RISK FACTORS

– Trauma and immobilization [1]

– Lying unconscious on hard surface under the influence of alcohol or drugs

– Crush injury

– Prolonged compression as seen in excessive operating times (esp. males)

– Laparoscopic, robotic, and open

– Dorsal lithotomy positioning

– Elevated BMI (esp. muscle mass)

– Seizs and shock

– Toxins (spider and snake venom [mostly in South America, Asia, Africa])

Medications [local anesthesia, itocain (MDMA), LSD, myoglobin, calcium, creatine kinase (CK), and lactic acid dehydrogenase (LDH)]

– Electrolyte and endocrine abnormalities

– Excessive muscle use (status epilepticus, prolonged exercise)

– Cardiac arrest (hypokalemia)

– Disseminated intravascular coagulation (DIC)

– Activation of the coagulation cascade by the substances released from damaged muscle cells

– Hepatic dysfunction

– Myoglobinuria acute renal failure

GENERAL PREVENTION

– Avoid immobilization or prolonged operating times

– Appropriate patient positioning in the operating room

– Some reports of using pulse oximetry monitoring of lower extremity to monitor for compartment syndrome

– Monitor for malignant hyperthermia

PATHOPHYSIOLOGY

– Muscle cell destruction

– Pressure or crush

– Cellular hypoxia

– Reparation injury results in large quantities of potassium, phosphate, myoglobin, CK, and urine leak into the circulation

– Electrolele abnormalities further impact cellular integrity

– Normal plasma myoglobin is very low (0–200 ng/mL)

– With > 100 g of skeletal muscle damaged, serum haptoglobin binding capacity becomes saturated

– At this point circulating myoglobin increases “free” and is filtered by the glomerulus

– Myoglobin precipitates in the kidney and causes renal tubular obstruction, potentially leading to acute kidney injury

– Myoglobin levels return to normal values in 1–6 hr after injury due to hepatic metabolism and renal excretion

– Up to 12 L of fluid may be sequestered in the neerosis muscle tissues

– This relative hypervolemia is an additional cause of renal failure in rhabdomyolysis

– Free iron, which catalyzes the production of free radicals, further enhances ischemic renal tubule damage

– Compartment syndrome

– Caused by insufficient blood supply to muscles due to increased pressure within a body compartment (arm, leg, any enclosed space within the body)

– 6 “Ps” associated with compartment syndrome:

– Pain out of proportion based on exam (arm, leg, any enclosed space within the body)

– Pain out of proportion to exertion

– Pain out of proportion to exercise

– Pain out of proportion to previous injury

– Pain out of proportion to treatment

– Pain out of proportion to activity

– Pain out of proportion to exam

– Myoglobin levels only appear in the urine when serum level > 1,000 U/L

– Myoglobin only appears in the urine when serum level > 100 mg/dL

– Red-brown urine

– Cyanotic discoloration

– Myoglobinuria

– Muscle pain and swelling

– Symptoms may be absent in 50% of patients

– Skin discoloration

– Muscular pain and swelling (symptoms may be out of proportion with exam)

– Muscle weakness

– Symptoms may be absent in 50% of patients

– Reddish-brown urine

– Classic triad of muscle pain, weakness, and dark urine

DIAGNOSTIC TESTS & INTERPRETATION

LAB

– Myoglobinuria

– Myoglobinuria only appears in the urine when serum level > 1,000 U/L

– Red-brown urine when urine levels > 100 mg/dL

– Positive for blood on urine dribble but no RBCs suggests myoglobinuria [5]

– Urine must be collected in ratios of 2:3:1, so it may return to normal if muscle damage is limited

– Elevated CK levels (5× upper limit of normal which is about 1,000 IU)

– CK–1/3 level of 26 hr and remains elevated longer than myoglobin, peaks at 1–3 days and declines at 3–5 days after all muscle injury has stopped

– Basic metabolic panel

– Monitor for acute renal failure and hyperkalemia

– Calcium level

– Can be hypercalcemic early, then hypercalcuric later

– Urine acid

– Conversion of purines from lysed muscle cells

– CBC/differential studies (for DIC)

– UFL, ABG

– Micorosopic urine: Pigmented casts, dysmorphic red cells

IMAGING

– Rarely necessary

– MRI with gadolinium best modality for muscle injury

– Sensitivity of 100% vs. 42% for US and 62% for CT scan

DIAGNOSIS

HISTORY

– Trauma

– Seizs

– New medication

– Toxic exposures, drug use or infection

– Excessive muscle use

– Electrolyte or endocrine disorder

– Prolonged operating room time—most common reason

– Needling (2.3.4)

– Most commonly reported in the laparoscopic nephrectomy data when patients are in flank or modified flank position for > 6 hr but also seen in exagerated lithotomy and steep Trendelenburg

– May see predominates

– Elevated BUN, reported mean BUN of 33.2 in review of the laparoscopic nephrectomy data

PHYSICAL EXAM

– Generalized fatigue, nausea, fever

– Mental status changes

– Skin discoloration

– Muscular pain and swelling (symptoms may be out of proportion with exam)

– Muscle weakness

– Symptoms may be absent in 50% of patients

– Reddish-brown urine

– Classic triad of muscle pain, weakness, and dark urine

446
Rhabdomyolysis

SURGERY/OTHER PROCEDURES

Chest x-ray imaging. 

The classic triad of muscle pain, weakness, and dark urine suggests rhabdomyolysis.

Limit operative times especially in obese and muscular patients. Consider high BMI as a risk factor for intraoperative rhabdomyolysis.

Some advocate not using a kidney rest/bar during laparoscopic surgery to help prevent rhabdomyolysis.

Appropriately pad all pressure points in the operating room.

Early recognition and aggressive hydration (better outcomes within the 1st 6 hr of presentation).

RHABDOMYOSARCOMA, PEDIATRIC (SARCOMA BOTRYOIDES)

Nicholas G. Cost, MD
Paul H. Noh, MD, FACS, FAAP

**DIAGNOSIS**

**HISTORY**
- Family history of malignancy or genetic syndromes
- Li–Fraumeni syndrome
- Neurofibromatosis
- Bezold tumor
- Autosomal dominant polycystic kidney disease
- 5q31 suppressor gene
- 11p15.5 suppressor gene
- 11p deletion
- 11p deletion

**RISK FACTORS**
- Incidence
- Epidemiology
- Incidence
- Bimodal age distribution
- 0.5–0.7 cases per million children
- Of all types of pediatric RMS15–20% involve GU
- Sarcoma botryoides describes a polypoid variant of RMS
- That tends to occur mostly in children
- Sometimes also called Embryonal Rhabdomyosarcoma
- Most common soft tissue sarcoma in children
- Incidence
- Epidemiology
- Incidence
- Bimodal age distribution
- 0.5–0.7 cases per million children
- Of all types of pediatric RMS15–20% involve GU
- Sarcoma botryoides describes a polypoid variant of RMS
- That tends to occur mostly in children
- Sometimes also called Embryonal Rhabdomyosarcoma
- Most common soft tissue sarcoma in children

**PATHOPHYSIOLOGY**
- The Latin word "botryoides" refers to the polypoid or "grape-like lesion" appearance of the tumor beneath the mucosa
- Some sources refer to this as "embryonal RMS"
- Rapid-growth with local invasion
- Can spread by lymphatic and hematogenous routes
- Thought to arise from immature cells that are destined to form striated skeletal muscle
- However, may arise in locations where skeletal muscle is not typically found, such as the bladder
- Defect in regulatory mechanism that controls proliferation and differentiation of skeletal muscle
- Prognosis and pattern of spread depend on histologic subtype and clinical staging
- Lymph nodes (LNs) and lungs are the most common sites of distant metastasis

**ASSOCIATED CONDITIONS**
See Genetics

**GENERAL PREVENTION**
None

**BASICS**

**DESCRIPTION**
- Rhabdomyosarcoma (RMS) (sarcoma botryoides) is a malignancy arising from embryonal mesenchyme that tends to occur mostly in children (Sometimes also called Embryonal Rhabdomyosarcoma)
- Most common soft tissue sarcoma in children
- Sarcoma botryoides describes a polypoid variant of RMS originating in a hollow viscus (vagina, bladder)
- Of all types of pediatric RMS15–20% involve GU system
- Paratesticular
- Bladder
- Prostate
- Uterus
- Vagina

**EPIDEMIOLOGY**
- Incidence
- Bimodal age distribution
- 1st peak: 2–4 yr
- 2nd peak: 15–19 yr
- 3rd most common solid tumor in children (behind neuroblastoma and Wilms tumor)
- Prevalence
- N/A

**RISK FACTORS**
- Genetics
- Li–Fraumeni syndrome
- Neurofibromatosis
- Bezold tumor
- Autosomal dominant polycystic kidney disease
- 5q31 suppressor gene
- 11p15.5 suppressor gene
- 11p deletion
- 11p deletion

**DIAGNOSTIC TESTS & INTERPRETATION**
- Laboratory investigations
- Complete blood count
- Basic metabolic panel
- Serum electrolytes
- Liver function tests
- Coagulation profile
- Tumor markers
- Cytogenetic abnormalities
- Loss of heterozygosity on chromosome 11
- 1;13 translocation (favorable prognosis)
- 2;13 translocation (unfavorable prognosis)
- X–Y translocation
- Cytogenetic abnormalities
- Loss of heterozygosity on chromosome 11
- 1;13 translocation (favorable prognosis)
- 2;13 translocation (unfavorable prognosis)
- X–Y translocation

**PHYSICAL EXAM**
- General
- Localized
- Abnormal masses
- Prolapse of ureterocele, urethra, vagina
- Ureteral obstruction
- Vaginal discharge/bleeding
- Scrotal swelling or pain
- Hematuria
- Urinary retention
- Stranguria
- Urinary frequency

**DIFFERENTIAL DIAGNOSIS**
- Benign adnexal mass
- Primary testicular tumor
- Nephrogenic adenoma of bladder
- Inflammatory pseudotumor of bladder
- Urothelial carcinoma
- Leiomyosarcoma
- Leiomyoma
- Ureteral or bladder diverticulum
- Wilms tumor
- Neuroblastoma
- Neurofibroma
- Neurofibrosarcoma
- Polypoid adenoma of bladder
- Sarcoma botryoides
- Other pediatric RMS

**TREATMENT**

**GENERAL MEASURES**
- Pre- and post-op staging and risk classification are critical in evaluation and treatment planning
- Prognostic staging: Intergroup Rhabdomyosarcoma Study (IRS) staging classification system based on TNM and primary location
- Prognostic grouping: IRS grouping based on primary resection
- TNM classification: Combines stage, group, and histology—helps determine therapy and prognosis
- Preoperative staging: TNM system
- T1: Confined to organ of origin
- T2: Extends to adjacent organs
- T3: Advanced, not systemically metastatic
- T4: Metastasis present
- N: Regional lymph node involvement
- M: Distant metastases
- Stage 1: Limited disease
- Stage 2: Intermediate disease
- Stage 3: Advanced disease
- Stage 4: Metastatic disease

**DIAGNOSTIC PROCEDURES/SURGERY**
- Biopsy
- Image-guided needle biopsy
- Preoperative staging: IRS staging classification system based on TNM and primary location
- Preoperative grouping: IRS grouping based on primary resection
- TNM classification: Combines stage, group, and histology—helps determine therapy and prognosis
- Prognostic staging: IRS system
- T1: Confined to organ of origin
- T2: Extends to adjacent organs
- T3: Advanced, not systemically metastatic
- T4: Metastasis present
- N: Regional lymph node involvement
- M: Distant metastases
- Stage 1: Limited disease
- Stage 2: Intermediate disease
- Stage 3: Advanced disease
- Stage 4: Metastatic disease

**Pathologic Findings**
- Embryonal:
- Accounts for majority of GU RMS
- embryonal variants associated with excellent prognosis
- Sarcoma botryoides
- Spindle cell rhabdomyosarcoma
- Alveolar:
- Less common in GU RMS
- More common in truncal/radial RMS
- Higher rates of local recurrence, LN spread, and distant metastasis
- Pleomorphic:
- Undifferentiated/anaplastic variant
- Poor prognosis

**RISK FACTORS**
- Genetics
- Li–Fraumeni syndrome
- Neurofibromatosis
- Bezold tumor
- Autosomal dominant polycystic kidney disease
- 5q31 suppressor gene
- 11p15.5 suppressor gene
- 11p deletion
- 11p deletion

**LABORATORY INVESTIGATIONS**

RHABDOMYOSARCOMA, PEDIATRIC (SARCOMA BOTRYOIDES)

- Postoperative grouping
  - Group I: Localized disease, completely excised, no microscopic residual
  - Group II: Infiltrating beyond site of origin, completely resected
- Vagina/uterine (1)
- Paratesticular
- Risk grouping
  - Low risk
    - Embryonal histology, Stage I, all groups
    - Embryonal histology, Stage II/III, Group I
    - Intermediate risk
      - Embryonal histology, Stage II/III, Group II
      - Alveolar histology, Stage I/II, Group I/II
    - High risk
      - Any histology, Stage IV
- All sites of GU RMS require a multidisciplinary approach to curative therapy including appropriate surgical excision, chemotherapy, and radiation (1)
- For bladder/prostate and vaginal/uterine RMS, chemotherapy is 1st-line therapy after biopsy and before radiation or extirpative surgery in all cases except rare instances amenable to immediate partial cystectomy with negative margins
- For paratesticular RMS, retroperitoneal staging is critical. Any boys <10 yr should have radiologic evidence of enlarged retroperitoneal LNs, and all patients >10 yr should have an ipsilateral retroperitoneal LN dissection (RPLND). This should be done to complete staging and must be done before chemotherapy or radiation (1).

MEDICATION
- First Line
  - Bladder/prostate
    - Low risk: Vincristine, actinomycin-D (VAC)
    - Low-risk N1, intermediate risk: VA + Cyclophosphamide (VAC)
  - Paratesticular
    - VA: Stage I, <10 yr, no evidence of LN involvement on imaging (1)
    - VAC: Positive LNs on RPLND
  - Vaginal/uterine (1)
    - VAC: Chemotherapy followed by repeat biopsy to assess residual disease
- Second Line
  - 2nd-line chemotherapy with addition of carboplatin, etoposide, vinblastine, or topotecan
  - Phase I studies

SURGERY/OTHER PROCEDURES
- Bladder/prostate
  - Partial cystectomy: Primary treatment in rare cases at descending urethra where adequate margins can be obtained
  - Radical cystectomy: Referred after chemotherapy or chemoradiation if tumor not amenable to bladder sparing options
  - Urinary diversion: Both temporary and permanent reconstructive options
- Radical prostatectomy: Performed for isolated prostate tumors after chemoradiation
- Paratesticular
  - Radical inguinal orchiectomy: All cases should be approached inguinally with radical resection
  - All >10 yr regardless of imaging
  - All >10 yr if evidence of LN involvement on imaging, prior to chemotherapy
- Vaginectomy: If evidence of residual disease on postchemotherapy biopsy

ADDITIONAL TREATMENT
- Radiation Therapy
  - Bladder/prostate: Postdiagnostic biopsy in addition to chemotherapy. Most cases (Group I)
    - Following initial attempted resection initial resection with residual margins, in addition to chemotherapy: Group I
  - Paratesticular
    - Positive LNs on RPLND
    - Vaginectomy
    - After chemotherapy or surgical resection unless an initial upfront resection (Group I)

Additional Therapies

ONGOING CARE

PROGNOSIS
- bladder/prostate: 3-yr disease-free survival (81%) (3)
- Vagina/uterine: 83% (Botryoid variant: 92%) (4)
- Embryonal: 83% (Botryoid variant: 92%) (4)
- Paratesticular: 3-yr disease-free survival: 81% (3)
- Overall survival: 96%
- Overall survival: 96% (3)
- 5-yr disease-free survival 68% (3)
- Overall survival: 8% (94%) for those <10 yr, 76% in those >10 yr (3)

COMPLICATIONS
- Bladder/prostate: Bowel obstruction
- Paratesticular: Complications of RPLND
- Vagina/uterine: Infertility
- Sexual dysfunction
- Chemotherapy-related toxicity
- Secondary malignancy

FOLLOW-UP
- Patient Monitoring
  - Postdiagnostic biopsy to assess for recurrent disease
  - Assessment of residual bladder/vaginal function

Patient Resources
http://www.curesearch.org/

Nicholas G. Cost, MD

ASSOCIATED CONDITIONS
- Tethered cord/hydronephrosis
- VACTERL/VATER association
- Curative syndrome
- Hemivertebra, anorectal malformations, and a presacral mass

GENERAL PREVENTION
Avoid material exposure to potentially causative agents

DIAGNOSIS

HISTORY
- Urinary tract infections (UTIs) in 75% of affected children
- Genetic/birth history
- Maternal drug exposure
- Gestational diabetes
- Urinary incontinence
- Constipation

PHYSICAL EXAM
- Lower extremity strength is usually normal
- Sacral dermatome sensation is usually intact
- Bowel function/constipation

DIAGNOSTIC TESTS & INTERPRETATION
- Magnetic resonance imaging (fetal or postnatal)
- Prenatal/postnatal ultrasound (US)
- Lateral x-ray of lower spine

BASICS

DESCRIPTION
- The partial or complete absence of 2 or more lower vertebral bodies
- May be occult or associated with voiding dysfunction

EPIDEMIOLOGY
Incidence
- 1 in 25,000 live births
- 16% of children with sacral agenesis (SA) have a diabetic mother
- 80% of cases are detected during infancy
- 20% of cases go undetected until difficulty with toilet training (at 3–4 yr of age)

Prevalence
- 1 in 25,000 live births
- 80% of cases are detected during infancy
- 16% of children with sacral agenesis (SA) have a diabetic mother
- Maternal insulin-dependent diabetes
- Maternal drug exposure (Minoxidil noted in case reports)

GENERAL MEASURES

Bladder management
- Consideration for clean intermittent catheterization regimen depending on status of ability to empty bladder and low pressure, state of the upper urinary tracts, and renal function status
- Potentially utilizing anticholinergics in the setting of high-pressure neurogenic bladder
- Bowel management
- Identity and treat constipation
- Anorectal manometry
- Orthopedic consultation

MEDICATION

First Line
- Oxybutynin (Ditropan)
  - Infants: 0.2 mg/kg PO TID
  - Children: 0.5 mg PO TID

Second Line
- Oxybutynin
  - Alternate anticholinergics, many not approved for children but used "off label"
SACRAL AGENESIS, UROLOGIC CONSIDERATION

SURGERY/OTHER PROCEDURES

- **UMN Lesions**
  - May require reconstructive surgery for the bladder outlet if there is concomitant incontinence from an open bladder neck.
  - Endoscopic injections of bulking agents to help with bladder neck continence
  - May require reconstructive surgery for the bladder outlet if there is concomitant incontinence from an open bladder neck.

- **LMN Lesions**
  - Endoscopic injections of bulking agents to help with bladder neck continence
  - May require reconstructive surgery for the bladder outlet if there is concomitant incontinence from an open bladder neck.
  - May require continent catheterizable channel (ie, Mitrofanoff)

- **Ureteral reimplantation or endoscopic bulking agent at the ureteral orifices for persistent VUR**

- **Bowel management may require enemas and even include the creation of a continent catheterizable channel for antegrade enemas (MACE [Malone antegrade continence enema])**

ADDITIONAL TREATMENT

- **Radiation Therapy**
  - N/A

- **Additional Therapies**
  - N/A

- **Complementary & Alternative Therapies**
  - N/A

ONGOING CARE

- **PROGNOSIS**
  - Best prognosis for successful toilet training and management of incontinence is when defect is detected early and when the child has normal lower extremity function.

- **COMPLICATIONS**
  - Renal function deterioration
  - Potential for high-pressure urinary storage transmitted to the kidneys which is deleterious for renal function.
  - Scarring from VUR and recurrent UTI
  - Social and developmental difficulties associated with fecal/urinary incontinence

FOLLOW-UP

- **Patient Monitoring**
  - Renal/bladder US at regular intervals
  - Monitor status of upper urinary tracts
  - Basic metabolic panel
  - Voiding cystourethrogram to follow status of VUR as needed
  - Urodynamics every year or every other year to ensure bladder is of a safe capacity and compliance to avoid a setup detrimental to renal health

- **Patient Resources**
  - The International Sacral Agenesis Caudal Regression Association (IASCRA)
  - https://sites.google.com/site/ caudalregressionsyndrome/

  - Caudal Regression Syndrome
  - Myelodysplasia (Spinal Dysraphism), Urologic Considerations
  - Neurogenic Bladder, General
  - Sacral Agenesis Image
  - Spina Bifida/Spina Bifida Occulta, Urologic Considerations
  - Tethered cord/Tethered Cord Syndrome
  - VACTERL/VATER Association

CODES

- **ICD9**
  - 344.61 Cauda equina syndrome with neurogenic bladder
  - 566.55 Detrusor sphincter dyssynergia
  - 756.13 Absence of vertebra, congenital

- **ICD10**
  - N32.81 Cauda equina syndrome with neurogenic bladder
  - N32.89 Other specified disorders of bladder
  - Q76.49 Other congenital malformations of spine, not associated with scoliosis

CLINICAL/SURGICAL PEARLS

- **There is variability in the level of neurologic insult and resulting in bladder dysfunction. This ranges from a UMN lesion with bladder hyperreflexia to an LMN lesion with areflexia.**
- **Aggressive medical management with anticholinergics and CIC may prevent renal damage and the need for major reconstructive surgery.**
SARCOIDOSIS, UROLOGIC CONSIDERATIONS
Jay Simhan, MD
Michael A. Pontari, MD

PATHOPHYSIOLOGY
- The cause of sarcoidosis is unknown. Symptoms are extensive and can involve pulmonary, arthritic, skin lesions, and manifestations relative to specific organ involvement.
- It is suspected that the granulomas of sarcoidosis are caused by an abnormal immunologic response to a stimulus.
- The most common presentation is pulmonary: Blalatral hilar adenopathy (40%). Less common is bilateral hilar adenopathy and pulmonary infiltrate (25%) and pulmonary infiltrate alone (15%). Other presenting manifestations include cough, wheezing, fever, malaise, fatigue, hepatosplenomegaly, splenomegaly, night sweats, and sweats.
- Hypercalcemia: Present in at least 20–30% of patients with sarcoidosis.
- Sarcoidosis may cause neoplastic hypercalcitria and uraemia.
- The sarcoid granuloma produces 1,25(OH)2D3 (calcitriol), causing increased intestinal absorption of calcium. Hypercalcemia: 60% develop hypercalcitria (HAs).
- Pulmonary alveolar cells and lymph node in patients with sarcoidosis are capable of synthesizing vitamin D; this is usually a function limited to the kidney.
- Most patients with sarcoidosis have a suppressed level of PTH secondary to hypercalcemia.
- Secondary hypercalciuria can be seen.
- Most sarcoidosis stones are calcium oxalate.
- Glomerular involvement is very rare and may include:
  - Membranous nephropathy, IgA nephropathy, minimal change disease, proliferative or crescentic glomerulonephritis, and local glomerulonecrosis.
  - Interstitial nephritis with granuloma formation is relatively common in sarcoidosis.
- Tubulointerstitial nephritis and uveitis (TNU) syndrome is lipodystrophic; these patients should be evaluated for sarcoidosis and lipogranuloma syndrome.
- Prostatic involvement has been reported.

ASSOCIATED CONDITIONS
Erythema nodosum

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Sarcoidosis can involve any organ system; the clinical presentation is variable and insidious.
- Patients most commonly present in winter and early spring, which suggests a possible environmental trigger.
- Cutaneous involvement is seen in 25% of patients with sarcoidosis. It may accompany systemic involvement.
- Fever, anemia, and polyarthralgia.
- Dyspnea on exertion, cough, chest pain, and occasionally hemoptysis.

PHYSICAL EXAM
- Cutaneous involvement may be present (bipapperm, erythema nodosum)
- Most common sites are face, upper back, trunk, or extremities (BIA)
- Wheezing
- Adenopathy
- Some cases of involvement of tests and epididymis, range from induration to painless mass
- Neurologic symptoms

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Erythrocyte sedimentation rate and mild proteinuria
- Leukopenia and/or lymphocytosis are common.
- Eosinophilia: 24%
- Anemia: 5%
- Hypercalcemia: 49%
- Hypercalciuria: 13%
- Elevated calcium levels
- Serum ACE level is elevated in 60% of patients; therefore, this test is not sensitive in diagnosing sarcoidosis.
- 90% and 2 C may be elevated if there is renal involvement.

Imaging
- Chest imaging may demonstrate hilar adenopathy or pulmonary infiltrate present in 90% of sarcoidosis patients.
- Abdominal imaging may show hepatomegaly, peripancreatic adenopathy, and perirenal fibrosis.
- Stones and nephrolithiasis secondary to hypercalciuria can be seen on CT.
- Sarcoid renal pseudotumors can mimic renal cell carcinoma, and more diffuse enlargement may mimic lymphoma. Retroperitoneal lymph nodes may enlarge sufficiently in sarcoidosis to cause obstruction.
- In rare cases of urinary involvement, underdiagnosis may be seen from urolithiasis or obstruction.
SARCOIDOSIS, UROLOGIC CONSIDERATIONS

TREATMENT

GENERAL MEASURES
- Sarcoidosis remains a diagnosis of exclusion. Before a definitive diagnosis can be made, multiple other conditions that can share similar symptomatology and pathologic findings must be ruled out (See “Differential diagnosis”) above.
- Coordination of care is suggested with experts in the management of the systemic and pulmonary manifestations of the disease.
- Corticosteroids are the mainstay of therapy for most manifestations of sarcoidosis.
- For sarcoidosis-related renal disease, the primary management is steroid therapy. Although many have poor renal function on presentation, patients may respond dramatically to steroid therapy. The steroids are given at high dose for 1–2 mo then reduced for the remainder of the course, which should be at least 1 yr.
- Hydration and limiting sodium intake can reduce hypercalcemia.

MEDICATION

First Line
- Oral corticosteroids are the treatment of choice for patients with hypercalcemia and systemic involvement.
- Initial prednisone 40 mg PO which is tapered to every other day over several weeks for long term therapy, typically 10–15 mg PO every other day
- Nephropathy due to sarcoidosis appears to respond to steroid therapy.

Second Line
- Wilks steroids
- Methotrexate
- Chloroquine

SURGERY/OTHER PROCEDURES
- Biopsy is necessary for diagnosis.
- Obstruction may require diversion.
- Surgical management of urolithiasis

ADDITIONAL TREATMENT

Radiation Therapy
- may

Additional Therapies
- N/A
- Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS
- The course of the disease is variable.
- Spontaneous remission occurs in 50% of patients.
- 1/3 of patients have eventual improvement.
- 10–30% of patients have chronic or progressive disease.

COMPLICATIONS
- Renal failure, interstitial nephritis, ureteral obstruction, neurogenic bladder dysfunction
- Nephropathy is rare and is due to hypercalcemic nephropathy.

FOLLOW-UP

Patient Monitoring
- History, physical exam, chest x-ray, pulmonary function tests, and serum chemistry

Patient Resources

REFERENCES

ICD9
- 105 Sarcoidosis
- 275.40 Unspecified disorder of calcium metabolism
- 952.0 Calculus of kidney

ICD10
- D86.9 Sarcoidosis, unspecified
- E83.52 Hypercalcaemia
- N32.0 Calculus of kidney

CLINICAL/SURGICAL PEARLS
- Sarcoidosis may cause urologic manifestations and hypercalcemia.
- Rapheovenous lymph nodes may enlarge sufficiently in sarcoidosis to cause obstruction.
- Consider a diagnosis of sarcoidosis in patients presenting with nephrolithiasis of unknown etiology, especially in an African American female.
- For sarcoidosis-related renal disease, oral corticosteroids is the mainstay of treatment.
SCROTUM AND TESTICLE, MASS
Jay Simhan, MD
Jack H. Mydlo, MD

BASICS

DESCRIPTION
A mass in the scrotum or testicle can be noted by the patient or during physical exam

• Location can be in scrotal wall, testicle, or paratesticular tissue

• Testicular masses can be distinguished from other common intrascrotal masses (Hydrocele, varicocele, spermatocoele, epididymal cyst, hematocele) based on exam or imaging studies

• Most palpable testicular tumors in adults are malignant: 80% nonpalpable lesions are benign.

• Children with testicular tumors are more likely to have benign lesions (20–40% benign).

EPIDEMIOLOGY

Incidence
9.837 cases of testicular cancer in the US in 2014 with 380 deaths

Prevalence
• Testicular tumors: 0.05–2/100,000 children

• Lifetime risk 1/270

RISK FACTORS

• Malnutrition, Cryptorchidism, prior testicular neoplasm or hematopoietic malignancy, HH family history of testicular cancer, marijuana use

• Benign mass: Recent trauma, UTI, STDs, viral illness, urethral instrumentation, congenital anomalies, previous history of scrotal surgery

Genetics

• Chromosome 12 alterations in testicular cancer: – Genetics associated in 33% of cases

– 2.2% incidence in brothers of patients with previous history of scrotal surgery

PATHOPHYSIOLOGY

• Depends upon the etiology of the mass

• Differential diagnosis can be narrowed based on patient’s age and history

ASSOCIATED CONDITIONS

Inguinal hernia in pediatric population

GENERAL PREVENTION

Note: testicular self-exam may help diagnosis

DIAGNOSIS

HISTORY

• Age of the patient

• Testicular tics are age-specific

• Torsion usually in prepubertal age group

• Description of the mass

• Small, discrete mass commonly neoplastic

• Diffuse enlargement with tenderness seen with infection, torsion, or trauma

• Associated pain

– Testicular: Sudden, severe, unilateral pain with nausea and vomiting. If torsion intermittent, pain may wax and wane, may have pain during sleep

– Neoplasms rarely cause severe pain, usually described as dull ache or fullness

– Orchitis pain may gradually increase as infection causes increased inflammation

• Referred pain to the scrotum without a mass can be due to renal colic, or nerve root irritation

• Prior scrotal surgery: Orchidectomy for cryptorchidism: increased risk of cancer; malignancy; posthitis granulomata

• History of trauma, surgery, any radiation

• Previous U/I or current lower U/I complaints suggests orchitis: epididymitis

• Urinal discharge suggests STD: concurrent epididymo-orchitis (Chlamydia and gonorrhea are most common in men <35 yr of age)

• Urinal instrumentation: Acquiring infection

• Current disease: Mumps, U/I

• Medical problems: Diabetes mellitus, immunodeficiencies, neurologic disorders, autoimmune disorders, others

• Fever, weight loss, nausea, vomiting, hemoptysis, shortness of breath, and back pain can all be clues to possible metastatic testicular neoplasm

• Nausea and vomiting in torsion or orchitis

ALERT

• Evaluate scrotal swelling and testicular masses urgently

• Solid, firm testicular mass must be considered testicular cancer until proven otherwise

• Patients may present with complaint of testicular mass when they have paratesticular mass instead.

PHYSICAL EXAM

• Never can be ruled out for infection, tumor necrosis, or testicular necrosis

• Mumps orchitis: 30% with mumps parotitis, onset 3–7 days following the parotitis

• Gynecomastia: Germ cell or Leydig cell tumor

• Abdomen:

– Focal tenderness or masses suggest metastasis

• Palpation:

– Retroperitoneal lymphadenopathy from metastatic tumors can sometimes be palpated

– Palpate for signs of hernia

Tumors:

- Size:

– Most early-stage neoplasms or cysts are palpable

– Evaluate if testicular vs. paratesticular mass

– Palpate for signs of hernia

- Temperature:

– Thawing testis and scrotum with flashlight

- Physical examination:

– Assess scrotal swelling and testicular masses

– Palpate for signs of hernia

- Palpate for signs of orchiectomy

Fever can be marker for infection, tumor necrosis, or testicular necrosis

Small, discrete mass commonly neoplastic

Torsion usually in prepubertal age group

Tumor types are age-specific

2.2% incidence in brothers of patients with previous history of scrotal surgery

Genetics associated in 33% of cases

Lab

- CBC to evaluate for anemia associated with malignancy

- Urine analysis and urine culture: May suggest the diagnosis of orchitis or epididymitis

- Hematologic and proteinase: Viral infection

- Pyuria and bacteriuria: Bacterial infection

- Tumor markers:

– AFP: Elevated in embryonal cell carcinomas, metastatic carcinomas, pink cell tumors, or combined tumors, but never increased in pure seminomas

– HCG: Elevated in all choriocarcinomas and some embryonal cell carcinomas, pink cell carcinomas, and seminomas

– LDH: Non-specific, elevated in metastatic disease

- Ultrasound: Rule out gonadoblastoma

Imaging (1)

- Ultrasonography: US (diagnostic procedure of choice): – 95% sensitivity for testicular tumor diagnosis

– Specificity for malignancies is lower since US detects benign lesions as well

- Most testicular tumors have hypoechoic areas, but overall heterogeneity of the lesion is common

- Color Doppler essential for the differentiation of torsion from epididymo-orchitis

– Decreased blood flow with torsion

– Increased blood flow with epididymo-orchitis

– Will also sometimes show increased vascularity in testicular neoplasms
DIFFERENTIAL DIAGNOSIS
See specific Section I and II topics.

Differential Diagnosis

- Adenocarcinoma of the rect testis
- Chylorch. Usually associated with visceral
- Fibrous pseudotumor of the tunica albuginea
- Hydrocele, primary or due to trauma, torsion, tumor, epididymo:hydrocele of the cord
- Orchiectomy of tunica vaginalis
- Paratesticular sarcoma: Rhabdomyosarcoma, mesothelioma, leiomyosarcoma, liposarcoma
- Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
- Scrotal wall: Sebaceous and inclusion cysts, idiopathic calcifications, fat necrosis, malignancy
- Spem granuloma following vasectomy
- Spermatocoele (epidermal cyst)
- Testicular cysts (simple, tunica albuginea, epididymo)
- Testicular tumor: Germ cell tumors (95% of testicular malignancies) are: Sertoli cell, granulosa cell tumors
- Metastatic tumors: Prostatic, lung, and GI tract
- Rare kidney: malformation, melanoma, parvocell, badder, and thyroid
- Mixed germ cell and stromal tumor
- Angioma, blepharochromocytoma, hemangioma, GCHS, melano, and neurofibrom
- Maligant fibrohistiocytoma (most common soft tissue cancer in late adult life)
- Lymphoma or lymphoma
- Varicocele
- Pediatric painless mass: Similar to adult list; most common are: Hydrocele, hemangi, scrococele, testicular teratoma, adrenal rest tumor, rhabdomyosarcoma

TREATMENT

GENERAL MEASURES
- Scrotal ultrasound is indicated in most cases of scrotal mass
- Testicular torsion is an emergency and requires immediate evaluation

MEDICATION

First Line
- Cause-specific treatment, as well as supportive care, should be applied to cases of orchitis. Bed rest, scrotal support, ice bags, and antibiotics.
- Broad-spectrum antibiotics should be administered if a bacterial source is suspected.
- A patient’s sexual partners should be treated if STD is the case.

Second Line
- N/A

SURGERY/OR OTHER PROCEDURES
- Testicular neoplasms: Radical orchietomy with high ligation of the spermatic cord, inguinal incision.
- Testicular biopsy or orchietomy through a scrotal approach is contraindicated if there is the possibility of neoplasm.
- Cystic lesions are difficult to differentiate from neoplastic lesions and are usually removed as above for testicular neoplasms.
- In children, tests: spacing surgery for benign lesions such as teratoma, Leydig cell tumor, and epithelial cyst based on frozen biopsy findings.

ADDITIONAL TREATMENT

Radiation Therapy
Seminoma or some sarcomas

Additional Therapies
Chemotherapy for advanced testicular tumors
Complementary & Alternative Therapies
- N/A

PROGNOSIS

In prepubertal patients, epididymo-orchitis

COMPLICATIONS

Infection, complications secondary to radiation or chemotherapy

FOLLOW-UP

Patient Monitoring
- Patients should be advised to perform monthly testicular self-exams.
- Patients diagnosed with cancer should have disease-specific follow-up.

Patient Resources

REFERENCES
SCROTUM AND TESTICLE, TRAUMA

Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

ASSOCIATED CONDITIONS

- Associated injuries
  - Urethra, corpora spongiosum
  - Corpus cavernosa
  - Testicular torsion
  - Testicular tumor

GENERAL PREVENTION

- Protective equipment during contact sports
  - Male雅 competing in boxing should wear the appropriate protective gear

DIFFERENTIAL DIAGNOSIS

- Trauma
  - Determine type of injury and magnitude of force
  - Investigate contamination of objects used in stab injuries

PHYSICAL EXAM

- Timing, severity, progression of pain, swelling, discoloration

DIAGNOSIS

- Testicular rupture is usually immediately painful followed by acute onset of swelling
- Torsion typically has more insidious progression of symptoms

PHYSICAL EXAM

- For testicular injury
  - Surgical exploration recommended for penetrating trauma

DIAGNOSTIC TESTS & INTERPRETATION

- Lab
  - Urinalysis
  - Blood culture if infection suspected

- For delayed presentation with abscess formation, culture abscess contents

DIAGNOSTIC TESTS & INTERPRETATION

- Imaging
  - Scrotal ultrasound
    - Highly sensitive and specific for hematocele, avulsion, and rupture
  - Evaluate integrity of tunica albuginea
  - Heterogeneous areas within testicular parenchyma is suggestive of testicular rupture
  - Doppler US may rule out torsion

DIFFERENTIAL DIAGNOSIS

- Trauma of the testicle or one of its appendages
  - Infection (epididymitis, orchitis)
  - Ruptured varicocele resulting in discoloration or tenderness
  - Pelvic fracture resulting in scrotal swelling

TREATMENT

- First Line
  - Narcotics as needed: Oral and IV
  - Protract testicular torsion
  - Pelvic fracture resulting in scrotal swelling

SURGERY/OTHER PROCEDURES

- Blunt trauma: Ruptured testis, expanding hematocele
  - Ruptured varicocele resulting in discoloration or tenderness

SELECTED REFERENCES

- Military services are developing devices for ballistic protection of the external genitalia

ADDITIONAL RESOURCES

- Proper safety training for industrial machinery
- Protective equipment during contact sports
- Testicular tumor
- Corpora cavernosa
- Urethra, corpora spongiosum
- Corpora cavernosa
- Testicular torsion
- Testicular rupture
- Scrotal ultrasound
- Heterogeneous areas within testicular parenchyma

- Evaluate integrity of tunica albuginea
- Doppler US may rule out torsion
- Infection (epididymitis, orchitis)
- Ruptured varicocele resulting in discoloration or tenderness
- Pelvic fracture resulting in scrotal swelling
SCROTUM AND TESTICLE, TRAUMA

FOLLOW-UP
Patient Monitoring
- Repeat US for conservatively managed patients
- Serum testosterone and fertility testing for patients with bilateral testicular injury

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Burns, External Genitalia and Penile
- Edema, External Genitalia
- Penile, Trauma
- Scrotum and Testicle, Trauma Algorithm
- Scrotum and Testicle, Trauma Images
- Testes Pain
- Torsion, Testes, and Testicular Appendages
- Urethra, Trauma (Anterior and Posterior)

CODES
ICD9
- 878.2 Open wound of scrotum and testes, without mention of complication
- 902.4 Contusion of genital organs
- 993.14 Other injury of external genitals

ICD10
- S30.22XA Contusion of scrotum and testes, initial encounter
- S31.31XA Laceration w/o foreign body of scrotum and testes, initial
- S39.94XA Unspecified injury of external genitals, initial encounter

CLINICAL/SURGICAL PEARLS
- Sonogram is the best technique to evaluate for testicular rupture.
- Heterogeneous areas within testicular parenchyma are more often suggestive of testicular rupture than defect in tunica albuginea on ultrasound.
- Repair testicular rupture whenever possible.
- Early exploration and repair of testicular injury is highly efficacious. Rupture of tunica albuginea of testicle in as many of 50% of blunt scrotal trauma presenting for evaluation. Prompt exploration and repair leads to improved salvage rates.
- In pediatric patients, painless hematocele after abdominal injury is a concern for ruptured viscera (especially spleen).
SCROTUM, SQUAMOUS CELL CARCINOMA

Lydia T. Laboccetta, MD
James S. Rosoff, MD

BASICS

DESCRIPTION
- Squamous cell carcinoma (SCC) of the scrotum is a very rare, environmentally induced cancer with high metastatic potential
- The first reported occupational cancer
  - Initially described in 1775 by Sir Percivall Pott in chimney sweeps
- Synonyms: Chimney sweeps cancer, Mule-spinners’ disease, Pott cancer

EPIDEMIOLOGY

Incidence
- 1.5-3/10 million men in US/1 similar rates noted in Dutch series (2)
- Increasing incidence in US may be related to increases in HPV infection, Psoralen plus ultraviolet light A (PUVA) treatment for psoriasis, and also due to improved reporting
- Lower incidence among black men in older series, though increased risk in black men in more recent SEER database analysis (1)
- Most reported in men > 50 yr; median age in SEER series: 68

Prevalence: N/A

RISK FACTORS
- Chemical/mechanical irritation
  - Classically described in chimney sweeps: Related to soot or chemical exposure, poor hygiene
- Oil/petroleum: Machine workers (lathe workers, spinning machines)
- Repeated trauma
- Rarely in patients with prior scrotal incision/scar
- Poor hygiene
- Oil/petroleum: Machine workers (lathe workers, spinning machines)
- Repeated trauma
- Poor hygiene

GENETICS
- N/A

PATHOPHYSIOLOGY

SCC: A malignant tumor of epidermal keratinocytes
- Usually a solitary, slow-growing nodule with or without ulceration usually on the anterolateral aspect of the scrotum
- Starts as a small pimple or nodule which gradually develops ulceration, raised or rolled edges, purulent discharge
- Lesion may persist for 6 mo before ulcerating
- May have associated condylomata of penis, scrotum, perianal region
- May lead to lymphadenopathy due to malignancy or infection
- 30-40% have palpable lymphadenopathy at presentation
- 25% have inguinal metastases at presentation

DIAGNOSIS

HISTORY
- Occupational exposure to chemical and/or mechanical irritants
- History of treatment for psoriasis
- History of HPV 16
- History of scrotal trauma, scrotal surgery
- Inflammatory conditions involving the scrotum
- Change in size of lesion or ulceration
- Fever
- Nonhealing nodule or ulcer

PHYSICAL EXAM
- Exam of external genitalia, inguinal and distant lymph nodes:
  - Usually a solitary, slow-growing nodule with or without ulceration
  - Lesion may persist for 6 mo before ulcerating
  - May have associated condylomata of penis, scrotum, perianal region
  - May lead to lymphadenopathy due to malignancy or infection
  - 30-40% have palpable lymphadenopathy at presentation
  - 25% have inguinal metastases at presentation

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- WBC count to rule out acute infection
- Urimalys and urine culture if indicated

IMAGING
- CT may help to assess size, extent of lymphadenopathy but cannot differentiate inflammation vs. malignancy
- MRI
  - Improved accuracy in diagnosis and staging
  - Can assess infiltrative vs. inflammatory process
  - Lymphangiography is accurate in delineating metastatic vs. inflammatory nodes, but cannot detect micrometastases

Pathologic Findings
- SCC
  - Most are well or moderately differentiated and contain focal areas of keratosis
  - Surrounding epidermis demonstrates hyperkeratosis, acanthosis, dyskeratosis
  - Diffuse lymphocytic infiltrate may be present
  - Staging staging for all scrotal carcinoma, not only SCC, no TNM classification exists (3)
  - Stage A1: Localized to scrotal wall
  - Stage A2: Locally invasive involving adjacent structures (testis, spermatic cord, penis, pubis, and perineum)
  - Stage B: Metastatic disease to the inguinal lymph nodes only
  - Stage C: Metastatic disease to the pelvic or lymph nodes without evidence of distant spread
  - Stage D: Metastatic disease beyond the pelvis including distant organs
- In SEER series, 76% presented with localized disease, 20% with regional metastases, and 4% with distant metastases (4)

DIFFERENTIAL DIAGNOSIS
- Benign scrotal lesions:
  - Condyloma
  - Eczema
  - Hidradenits suppurativa
  - Folliculitis
  - Nevus
  - Periurethral abscess
  - Psoriasis
  - Tuberculosis epidemic inclusion cyst
  - Sebaceous cyst/epidermal inclusion cyst
  - Tuberculosis: epididymitis with a draining sinus
  - Syphilis
  - Sebaceous cyst
  - Malignant melanoma
  - Basal cell carcinoma
  - Paget disease
  - Marjolin ulcer: Cancer arising from site of prior inflammation
- Tuberculosis: epididymitis with a draining sinus
- Malignant scrotal lesions:
  - Basal cell carcinoma
  - Malignant melanoma
  - Paget disease
  - Malignant scar: Cancer arising from site of prior inflammation
- Kaposi sarcoma: A purple, papular, plaque-like, or nodular lesion on the penis or scrotum
- Sarcoma: Lymphangioma from the Darts layer of the scrotum is most common, though still very rare

ASSOCIATED CONDITIONS
- HPV/condylomata
- Psoriasis
- Associations with many other carcinogens have been described

DIAGNOSTIC PROCEDURES/SURGERY
- Excisional biopsy of primary lesion

ASSOCIATED CONDITIONS
- HPV/condylomata
- Psoriasis
- Associations with many other carcinogens have been described

DIAGNOSTIC PROCEDURES/SURGERY
- Excisional biopsy of primary lesion
SCROTUM, SQUAMOUS CELL CARCINOMA

TREATMENT
GENERAL MEASURES
• Management is primarily surgical.
• Local wide excision is diagnostic and therapeutic.
MEDICATION
First Line
• Broad-spectrum antibiotics for 4–6 wk in patients with lymphadenopathy
• Chemotherapy has not demonstrated success for primary treatment (single agent or combination therapy)
  – Methotrexate, bleomycin, and cisplatin have been used with radiotherapy in 1 case report, but the patient later required surgical resection
  – Bleomycin has been reported as successful in 2 cases
  – Multiple case reports exist in the literature of combined adjuvant chemotherapy and radiotherapy
• Topical 5-FU has not been successful in treating carcinoma in situ of the scrotum
Second Line
• N/A
SURGERY/OTHER PROCEDURES
• Primary lesion:
  – Wide local excision of lesion with a 2-cm margin of skin and dartos fascia.
  – Small lesions may be closed primarily.
  – Large lesions may require split-thickness skin grafting or local flaps.
  – If hemiscrotectomy is performed, the ipsilateral testis may be placed in a thigh pouch or moved to the contralateral hemiscrotum.
  – Excision of all scrotal contents is required only when structures are directly involved by tumor.
• Regional lymph nodes
  – If palpable adenopathy resolves after antibiotics or was never present, then a superficial inguinal lymph node biopsy should be performed:
    ○ Ipsilaterally if lesion is lateral
    ○ Bilaterally if lesion at the median raphe
  – If palpable lymphadenopathy persists after antibiotics, then a bilateral superficial lymph node biopsy should be performed.
  – Full bilateral lymphadenectomy should be performed only on the side of the positive biopsy:
    ○ If performing a unilateral lymphadenectomy, a contralateral superficial inguinal lymph node biopsy should also be performed.
  – If there is a positive frozen section, then perform a bilateral lymphadenectomy.
• Laser vaporization of the primary lesion has been used in poor surgical candidates or those who refused surgery.
• Mohs micrographic surgery has also been used for primary lesions.

ADDITIONAL TREATMENT
Radiation Therapy
• Has not been effective and is reserved for recurrences and poor surgical candidates.
• Has been described in multiple case reports as adjuvant therapy.
Additional Therapies
• N/A
Complementary & Alternative Therapies
• N/A

ONGOING CARE
PROGNOSIS
• Scrotal cancer survival is worse for SCC histology than all other histologies except melanoma
  – Survival at 5 yr (1):
    ▪ Stage A: 70–80%
    ▪ Stage B: 40–50%
    ▪ Stage C: Rare
    ▪ Local recurrence rates:
      ▪ 21–40%
      ▪ May require additional excision
      ▪ Patients with industrial exposure may be at higher risk for recurrence
COMPLICATIONS
• Femoral hernias after ilioinguinal lymphadenectomy
• Lymphedema
• Lymphoceles
• Wound infections
FOLLOW-UP
Patient Monitoring
• Self-exams for local recurrence of lesion or lymphadenopathy
• Periodic follow-up by physician for monitoring of local recurrence or lymphadenopathy
• Follow-up is required for life
Patient Resources
• N/A

ICD10
C63.2 Malignant neoplasm of scrotum

CLINICAL/SURGICAL PEARLS
A nonhealing ulcer or nodule on the scrotum should raise suspicion for squamous cell carcinoma.

459
SEMINAL VESICLE, CYSTS AND MASSES

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

PATHOPHYSIOLOGY

Genetics

RISK FACTORS

Prevalence

N/A

DIAGNOSIS

HISTORY

Most SV cysts are asymptomatic

When symptomatic, typical symptoms are:

- Dysuria, irritative voiding
- Hematuria
- Hematospermia
- Intersitial

Diagnose other malignancy such as prostate cancer

PATHOPHYSIOLOGY

Normal anatomy:

- SVs are elongated, flat, paired structures that lie between the rectum and bladder, superior to the prostate.
- Mean normal length is 3.1 cm and width is 1.5 cm; contributes 50–80% of total seminal ejaculatory volume
- Blood supply: Vascular/venous network; artery, branch of the umbilical artery
- Cysts disease of the SVs can be either congenital or acquired; congenital cysts are associated with anomalies of the ipsilateral mesonephric duct.
- Acquired SV cysts result from ejaculatory duct obstruction, inflammation, or other abnormality.
- Cysts are filled with seminal fluid (nonmotile spermatozoa, red and white blood cells, and epithelial cells).

Congenital SV cysts are typically associated with an ipsilateral ectopic center and/or (ipsilateral renal abnormalities):

- Lesions <5 cm are slowly symptomatic.
- Lesions >12 cm have been described as giant cysts and are often associated with symptoms related to bladder outlet or colonic obstruction.

In men, 30% of ectopic centers insert into the SV.

3 patterns of spread of prostate cancer into SV

1. Direct spread along the ejaculatory duct
2. Prostatic capsule perforation followed by extension into the prostatic tissue and the SV
3. Isolated deposits

Direct invasion of the SVs can also occur in malignancies of the bladder and rectum

ASSOCIATED CONDITIONS

Bladder cancer
Ectopic ureter
Bilateral renal dysplasia or agenesis
Prostatic cancer
Rectal cancer

GENERAL PREVENTION

N/A

DIAGNOSTIC TESTS & INTERPRETATION

Lab

PSA elevation may suggest prostate cancer.

IMAGING

TRUS (transrectal ultrasound):

- Tomography for suspected SV abnormality or SV mass on DRE

- SV cystic lesion: Echogenic center with echogenic peripheral halo

- SV tumors: Isoechoic to the prostate, but hyperechogenic to normal SV

CT:

- SV tumors: Enlarged SV with a high attenuation lesion and a normal bladder and prostate. Can be cystic if there is significant tumor necrosis

- Cannot distinguish benign from malignant tumors. Dilated tissue planes suggest a secondary tumor by direct extension

MRI:

- Cannot distinguish benign from malignant tumors
- SV cyst: T1; low signal intensity, T2; unidirectional smooth wall with uniform high intensity and well-defined margin

- Hemorrhagic SV cyst: High intensity on both T1 and T2; heterogeneous intensity

Diagnostic Procedures/Surgery

Cystoscopy

- Hematospermia with absent or reduced orifice

- Intracystic cyst aspiration and noted with congenital SV cyst

TRUS-guided needle placement for SV aspiration or biopsy for pathologic diagnosis

Uroscopy. Limited value and use today in imaging the SV. Can help determine duct obstruction in azoospermic men; also helps distinguish SV cyst from a mullerian or other wolffian duct cyst

Pathologic Findings

Most primary SV masses are benign and rarely neoplastic
**SEMINAL VESICLE, CYSTS AND MASSES**

- **SV cysts**
  - Symptomatic: SV infection is uncommon.
  - May occur as a consequence of prostatitis or epididymitis.
  - SV abscess: Best imaged on MRI or US.
  - Presumably factors include diabetes or chronic infection.
- **SV calculi**: Often present with pain, infection, or hematospermia; usually the result of infection and ejaculatory duct obstruction.
- Congenital cysts: Congenital cysts are typically associated with ipsilateral epididymal, seminal vesicular, and/or ipsilateral renal dysplasia.
- Benign SV tumors:
  - Papillary adenoma or cystadenoma: Middle-aged men, minimally invasive cyst in presentation and on imaging.
  - Arteriovenous malformations of the SV: Usually presents in the elderly.
  - Often coexistent with bladder or prostate cancer.
- **Other rare tumors**:
  - Carcinoid.
  - Mixed SV tumors are extremely rare:
    - Only 15 cases reported.
    - Variously described as cystadenoma, cystomyoma, low-grade phyllode tumor, benign mesenchymoma, adenomyoma, and mesonephric hamartoma.
- Malignant SV tumors:
  - SV neoplasms are from secondary invasion from prostate, bladder, or rectal cancer, or from other sites.
  - Direct extension into the SV can often be mistaken for primary SV cancer.
  - Primary adenocarcinoma of the SV:
    - Age >50 yr, incidence is rare.
    - Serum PSA and PAP are normal, and CA125 elevated.
    - Tumors positive for CA125 and negative for PSA.
  - Primary carcinoma:
    - Extremely rare aggressive tumor, usually diagnosed late in disease course.
    - Tumors: Leydigoma, angiosarcoma, and mesenchymal adenocarcinoma.
- **SV invasion by another malignancy**: Direct involvement of SV by prostate, bladder, or rectal cancer, or from other sites.
- **SV invasion by another malignancy**: Extensively described as cystadenoma, cystomyoma, low-grade phyllode tumor, benign mesenchymoma, adenomyoma, and mesonephric hamartoma.
- **Malignant SV tumors**:
  - Most SV neoplasms are from secondary invasion from prostate, bladder, or rectal cancer, or from other sites.
  - Direct extension into the SV can often be mistaken for primary SV cancer.
  - Primary adenocarcinoma of the SV:
    - Age >50 yr, incidence is rare.
    - Serum PSA and PAP are normal, and CA125 elevated.
    - Tumors positive for CA125 and negative for PSA.
  - Primary carcinoma:
    - Extremely rare aggressive tumor, usually diagnosed late in disease course.
    - Tumors: Leydigoma, angiosarcoma, and mesenchymal adenocarcinoma.
  - SV invasion by another malignancy: Directed at the primary tumor type.
- **Additional treatment**
  - Radiation Therapy.
  - Chemotherapy.
  - Immunotherapy.
  - Targeted therapy.
  - Hormone therapy.
  - Surgery.
- **Prognosis**
  - Primary SV malignancies due to their rarity, typically present at an advanced stage and are diagnosed late.
  - SV invasion by another malignancy: Directed at the primary tumor type.
  - SV invasion by another malignancy: Diagnosis and management of seminal vesical cysts associated with ipsilateral renal agenesis.
- **Follow-up**
  - Asymptomatic benign tumors: Close follow-up with DRE and TRUS. Other radical surgery for malignancy, no clear follow-up consensus exists.
- **Patient Monitoring**
  - Asymptomatic benign tumors:
    - Close follow-up with DRE and TRUS. Other radical surgery for malignancy, no clear follow-up consensus exists.
- **Patient Resources**
  - N/A.
- **ADDITIONAL READING**
- **CODES**
  - 198.82 Secondary malignant neoplasm of general organs.
  - 608.6 Benign vesicles.
  - 608.89 Other specified disorders of male genital organs.

  - N49.3 Inflammatory disorders of seminal vesicle.
  - N60.8 Other specified disorders of male genital organs.
- **CLINICAL/SURGICAL PEARLS**
  - Hematospermia can be a sign of underlying malignancy.
  - SV calculi are typically associated with ipsilateral renal agenesis.
  - If secondary malignancy is present, treatment should be directed at the primary tumor type.
  - If secondary malignancy is present, treatment should be directed at the primary tumor type.
- **ONGOING CARE**
  - SV calculi: Often concomitant with bladder or prostate cancer.
  - SV duct stones: Lithotripsy is feasible in select patients via a ureteroscope.
  - SV tumors:
    - All solid or noncystic SV masses on TRUS should undergo a US-guided biopsy.
    - If tumor is confirmed: Further stage with CT and MRI.
  - Enlarging asymptomatic benign tumors are treated with simple seminal vesiculectomy.
  - Historically, small benign tumors were excised transperitoneally or retroperitoneally, and large tumors, transvasically or transcotally.
  - Today, excisions are typically by transperitoneal laparoscopy (case series are small).
  - A diagnosis of malignancy (large in size or poorly differentiated) warrants radical cystoprostatectomy and regional lymph node dissection, en bloc with adherent surrounding structures.
- **ADDITIONAL TREATMENT**
  - Radiation Therapy.
  - Chemotherapy.
  - Immunotherapy.
  - Targeted therapy.
  - Hormone therapy.
  - Surgery.
- **Prognosis**
  - Primary SV malignancies due to their rarity, typically present at an advanced stage and are diagnosed late.

**SEXUAL ABUSE, PEDIATRIC**

Monica M. Metzdorf, MD
Julia S. Barthold, MD, FACS

**BASICS**

**DESCRIPTION**
- Sexual activity involving a child or a minor
- Spectrum of pediatric sexual abuse includes intercourse, fondling, pornography, and exhibitionism

**EPIDEMIOLOGY**
- Incidence:
  - ∼1% of children sexually abused each year
- Prevalence:
  - 12–20% of girls and 8–10% of boys have been sexually abused by age 18 (12–40% overall)
  - Of girls reporting abuse (1):
    - 12–25% of girls and 8–10% of boys have been sexually abused by age 18 (12–40% overall)
    - 53% reported that the abuse occurred at home

**RISK FACTORS**
- Occurs in all socioeconomic levels
- Gender:
  - Girls more likely to be abused
- Parental abuse:
  - Increased risk with:
    - Physical abuse
    - Emotional abuse
    - Sexual abuse
- Parents who were abused:
  - Increased risk
- Poor hygiene:
  - Increased risk
- Mental illness:
  - Increased risk
- Poverty:
  - Increased risk
- Multiple child caretakers:
  - Increased risk
- Teen parents:
  - Increased risk

**PATHOPHYSIOLOGY**
- American Academy of Pediatrics definition (2):
  - Sexual abuse is the engaging of a child in sexual activities that the child cannot comprehend, and cannot give informed consent, and that violates the social taboos of society.
- Children cannot consent to any sexual activity, but can be sextually abused if they are developmentally unprepared and cannot give informed consent, and that violates the social taboos of society.

**ASSOCIATED CONDITIONS**
- Physical abuse
- Emotional abuse

**GENERAL PREVENTION**
- Education
- Social services

**DIAGNOSIS**

**ALERT**
- Findings in the evaluation of children with possible injuries to the external genitalia that should raise concern for sexual abuse include:
  - Presence of other nonurogenital trauma.
  - Patient < 9 yo.
  - Perianal, rectal injury without history of penetrating trauma.
  - Findings of more extensive or severe trauma.
  - Lack of correlation between reported history and physical findings.

**HISTORY**
- Child may make a statement of abuse, or abuse is witnessed
- Child brought by law enforcement/social services for evaluation for possible abuse as part of investigation
- Caregiver suspects child may have been abused
  - Suspicious findings on routine exam
- Suspicious complaints:
  - Rectal or vaginal bleeding or discharge, especially in prepubertal child
  - Presence of semen, sperm, or acid phosphatase;
    - When severe rectal injury suspected, persistent bleeding or full-thickness lacerations, consider exam under anesthesia.
  - Exam findings of concern:
    - Abnormal discharge or bleeding of genitalia.
    - Acute or healed tear in posterior aspect of hymen.
    - Hemorrhage or swelling of hymen.
  - Injury or scarring of posterior fourchette, fossa navicularis, or hymen.
  - Anal bruising or lacerations.

**DIFFERENTIAL DIAGNOSIS**

**LAB**
- Culture for gonorrhea and Chlamydia.
- Vaginal foreign body
- Blood in urine
- Premenarchal females should have pregnancy test.
- Presence of semen, sperm, or acid phosphatase:
  - Positive culture for gonorrhea or Chlamydia, or a positive test for syphilis or HIV
- All postmenarchal females should have pregnancy test.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Imaging**
- Imaging should be performed if suspicious physical findings are noted.

**DIFFERENTIAL DIAGNOSIS**

**Surgical Procedures**
- Consider exam under anesthesia.

**CONSIDER EXAM UNDER ANESTHESIA**

**PHYSICAL EXAM**
- Be familiar with the normal appearance of the prepubertal introitus and hymen (image).
- Do not force exam on uncooperative children.
- Do not use speculum in prepubertal child.
- Do not touch hymen with swabs or other objects.
- Do not perform a digital rectal exam (DRE).
- Educate caretaker and patient that most sexually abused children have a normal physical exam.
- Absence of physical findings does not exclude abuse
- Perform complete physical exam including skin, oropharynx, genitalia, and anal area.

**ALERT**
- Use frog-leg position with gentle labial traction to visualize female anatomy.
- Consider exam in chest-knee position to confirm suspected abnormalities.
- Consult specialists as appropriate.
- Document thoroughly exam findings and descriptions, using drawings or photos if feasible.
- When severe rectal injury suspected, persistent bleeding or full-thickness lacerations, consider exam under anesthesia.
- Exam findings of concern:
  - Abnormal discharge or bleeding of genitalia.
  - Acute or healed tear in posterior aspect of hymen.
  - Hemorrhage or swelling of hymen.
  - Injury or scarring of posterior fourchette, fossa navicularis, or hymen.
  - Anal bruising or lacerations.

ONGOING CARE

PROGNOSIS
- Need for mental health support, especially in:
  - Patients reporting suicidal or self-injurious thoughts
  - More intrusive forms of assault
  - More violent assaults
  - Longer period of molestation
  - Closer relationship of perpetrator to victim

COMPlications
- Psychological
  - Eating disorders
  - Depression and anxiety
  - Suicidal behaviors
  - Self-injury
- Posttraumatic stress disorder
- Sexual dysfunction
- Pregnancy
- STIs/STI's

FOLLOW-UP
Patient Monitoring
- Follow-up exams for healing of injuries
- Evaluation for development of STIs
- Evaluation for development of pregnancy and discussion of this possibility with the postpubertal child
- Emotional support/therapy

Sexual Abuse, Pediatric Image

CODES
ICD9
- 995.33 Child sexual abuse
- 715.41 History of physical abuse

ICD10
- T74.22XA Child sexual abuse, confirmed, initial encounter
- T76.22XA Child sexual abuse, suspected, initial encounter

CLINICAL/SURGICAL PEARLS
- Pediatric providers should always alert to signs and symptoms that suggest the possibility of sexual abuse.
- The clinician is obligated to report any suspected case of childhood sexual abuse.
- Sensitivity during the history and exam and providing the victim access to psychological and social work support are key factors in the case of children who have been sexually abused.
SEXUAL DYSFUNCTION, FEMALE

Samuel Walker Nickles, MD
Nima Baradaran, MD
Eric S. Roener, MD, FACS

BASICS

DESCRIPTION
Sexual dysfunction is a disorder involving sexual desire, orgasm, arousal, or sexual pain in females that results in significant personal distress. It includes the following:
- Hypoactive sexual desire disorder
- Subjective sexual arousal disorder
- Sexual pain disorder
- Combined genital and subjective arousal disorder
- Persistent sexual arousal disorder
- Sexual anorgasmic disorder
- Menopause
- Vasculogenic
- Neurogenic
- DSM-IV defines female sexual dysfunction (FSD)
- Dyspareunia
- Women's orgasmic disorder
- Sexual aversion disorder
- Persistent sexual arousal disorder
- Combined genital and subjective arousal disorder
- Subjective sexual arousal disorder

ASSOCIATED CONDITIONS
- Depression
- Endometriosis, vulvodynia, etc.
- Urinary incontinence
- Intercourse
- Menopause
- Multiple sclerosis
- Any disease that causes decreased estrogen or androgens

GENERAL PREVENTION
- Lifestyle modification to reduce CV disease or premature aging affect sexual desire and response
- Medications
- Previously prescribed medications can decrease sexual desire and function
- Prior pelvic surgery such as hysterectomy or cystectomy can disrupt the autonomic nerve plexus, thus contributing to sexual dysfunction
- OCP, biogenic estrogens

PHYSICAL EXAM
- A thorough physical and pelvic/manual exam:
  - Assess for vaginal atrophy, labia minora, vaginal depth, genitopelvic sensation
  - Examine for trigger points, scarring, or narrowing from prior surgery or genital infection
  - Assess for prolapse, masses
- If neurologic signs are present, a more detailed neurologic assessment is then warranted including anal and vaginal tone, bulbocavernosal reflex, and voluntary tightening of the anus

DIAGNOSTIC TESTS & INTERPRETATION
- Basic chemistry panel, CBC, TSH, and lipid profile to help identify chronic medical conditions, renal failure, diabetes, or hypothyroidism
- Hormonal profile
- Serum total and free testosterone
- Estradiol level
- LH, FSH, prolactin
- Sex hormone binding globulin (SHBG)

Imaging
- Vaginal and clitoral phthlymography, duplex US, and selective pudendal angiography can be used to assess genital blood flow.

DIFFERENTIAL DIAGNOSIS
- Vascular causes of decreased estrogen or androgen action
- Neurogenic causes due to multiple sclerosis, spinal cord injury, or pelvic trauma
- Neuropathic causes (diabetes, peripheral vascular disease, etc.)
- Medication-related effects

LAB
- Basic chemistry panel, CBC, TSH, and lipid profile to help identify chronic medical conditions, renal failure, diabetes, or hypothyroidism
- Hormonal profile
- Serum total and free testosterone
- Estradiol level
- LH, FSH, prolactin
- Sex hormone binding globulin (SHBG)

Pathologic Findings
- Vascular
- Neurologic
- Psychogenic

PHYSICAL EXAM
- A thorough physical and pelvic/manual exam:
  - Assess for vaginal atrophy, labia minora, vaginal depth, genitopelvic sensation

- Estradiol level
- LH, FSH, prolactin
- Sex hormone binding globulin (SHBG)

Imaging
- Vaginal and clitoral phthlymography, duplex US, and selective pudendal angiography can be used to assess genital blood flow.

Diagnostic Procedures/Surgery
- Genital/vaginal sensation threshold testing, genital temperature sensation, and the bulbocavernosal reflex can be evaluated to rule out associated neurologic dysfunction

Pathologic Findings
- Vascular
- Neurologic
- Psychogenic

PHYSICAL EXAM
- A thorough physical and pelvic/manual exam:
  - Assess for vaginal atrophy, labia minora, vaginal depth, genitopelvic sensation
  - Examine for trigger points, scarring, or narrowing from prior surgery or genital infection

Pathologic Findings
- Vascular
- Neurologic
- Psychogenic

PHYSICAL EXAM
- A thorough physical and pelvic/manual exam:
  - Assess for vaginal atrophy, labia minora, vaginal depth, genitopelvic sensation
  - Examine for trigger points, scarring, or narrowing from prior surgery or genital infection
  - Assess for prolapse, masses
- If neurologic signs are present, a more detailed neurologic assessment is then warranted including anal and vaginal tone, bulbocavernosal reflex, and voluntary tightening of the anus

DIAGNOSTIC TESTS & INTERPRETATION
- Basic chemistry panel, CBC, TSH, and lipid profile to help identify chronic medical conditions, renal failure, diabetes, or hypothyroidism
- Hormonal profile
- Serum total and free testosterone
- Estradiol level
- LH, FSH, prolactin
- Sex hormone binding globulin (SHBG)

Imaging
- Vaginal and clitoral phthlymography, duplex US, and selective pudendal angiography can be used to assess genital blood flow.

Diagnostic Procedures/Surgery
- Genital/vaginal sensation threshold testing, genital temperature sensation, and the bulbocavernosal reflex can be evaluated to rule out associated neurologic dysfunction

Pathologic Findings
- Vascular
- Neurologic
- Psychogenic

**SEXUAL DYSFUNCTION, FEMALE**

**TREATMENT**

**GENERAL MEASURES**
- Attempt to identify a correctable cause and treat when present.
- Exercise and pelvic floor training/massage can improve sexual function.

**MEDICATION**
- Treat prolapse and incontinence in affected patients, as female sexual dysfunction may be in part related to its inhibition due to leakage during sexual relations.

**First Line**
- Hormone replacement therapy (HRT) is the mainstay of treatment in postmenopausal women or oophorectomized women (4).
  - Oral estrogen or topical vaginal estrogen may improve libido and ameliorate symptoms of dysosmia or irritation.
  - Oxytocin is an estrogen agonist/antagonist indicated for the treatment of moderate to severe dyspareunia, a symptom of vulvar and vaginal atrophy, due to menopause.
  - One tablet (60 mg) taken orally once daily with food.
  - Do not use estrogens or estrogen agonist/antagonist or fluconazole concomitantly.
- Topical steroids for genital edema.
- Androgen replacement therapy can be considered in patients with androgen deficiency.
  - Combined estrogen and testosterone replacement therapy can be used or testosterone alone can be applied topically or with a patch (counsel patient on risks of virilization including: Acne, hirsutism, male pattern baldness, and clinical hypertrichosis).
- Testosterone replacement is controversial and not FDA approved despite being one of the most commonly prescribed off label drugs for desire disorders.
- Tibolone (synthetic steroid) is commonly used in Europe in postmenopausal women with desire and arousal disorders.

**Second Line**
- Androgen replacement therapy can be considered in patients with androgen deficiency.
- Computerized and testosterone replacement therapy can be used or testosterone alone can be applied topically or with a patch (counsel patient on risks of virilization including: Acne, hirsutism, male pattern baldness, and clinical hypertrichosis).

**ADDITIONAL TREATMENT**

**Radiation Therapy**

**Additional Therapies**
- Eros Critical Therapy Device is a handheld mechanical device that has been FDA approved for the treatment of sexual arousal and orgasmic disorders in women.
- Several other pharmacologic agents are under investigation for treatment of female sexual dysfunction.
- PDE-5 inhibitors are thought to enhance vaginal lubrication and enjoyment in postmenopausal women; however, the benefit is not well established.
- α-Adrenergic antagonists such as phentolamine and yohimbine produce vasodilatation of the smooth muscle, increasing vaginal blood flow and lubrication.

**Complementary & Alternative Therapies**
- Education, sex therapy, psychotrapey, and cognitive behavioral therapy are also important in the multidisciplinary management of sexual dysfunction including those with a history of sexual abuse.
- Currently there are limited studies on the effectiveness of herbal remedies to aid female sexual dysfunction.

**ONGOING CARE**

**PROGNOSIS**
- Outcome is improved if a specific cause can be identified.

**COMPLICATIONS**
- Patients on HRT should be appropriately counseled on its risks and benefits.

**FOLLOW-UP**
- Patient Monitoring
  - Close monitoring of progress and compliance is necessary.

**CLINICAL/SURGICAL PEARLS**
- FSD is a complex condition with many etiologies.
  - A multidisciplinary approach is often necessary.
  - Search for reversible cause such as incontinence or prolapse and treat accordingly.

**REFERENCES**
PATHOPHYSIOLOGY

- Transmission is primarily via sexual contact.
- Nonsexual transmission: Mother–infant, blood transfusions, accidental needle injury.

RISK FACTORS

- Prevalence

EPIDEMIOLOGY

- Incidence
- Prevalence
- Risk factors

Gender

- CCR5 mutation provides relative protection against HIV infection (2C1)

STI

- Ulcerative lesions
- Exposure at delivery and/or in utero
- Low socioeconomic status, drug abuse
- Multiple sex partners, sexual contact with infected person

Prevalence

- 20 million new infections yearly (1A)
- Relative frequency of cases by disease: HPV > Chlamydia > Trichomonas > Gonorrhea > HSV-2 > syphilis > HIV > Hep B
- 50% of new STIs in patients 15–24 yr old

110 million STIs estimated by the Centers for Disease Control and Prevention (CDC) (1A)

Most prevalent STI is human papilloma virus (HPV)

- 25% STIs are incurable (HIV, HSV-2, Hep B)

25% of women are symptomatic, and can have a mucopurulent cervical discharge

40% of untreated women will develop pelvic inflammatory disease (PID), PID is associated with infertility and ectopic pregnancy

Associated conditions

- HPV 6 and 11 tend to cause warts, HPV 16, 18, 31, 33, and 35 are high risk for cellular dysplasia and increase cancer risk
- Condyloma acuminate (HPV)
- Condyloma lata (Trichomonas)
- Serologic: Nonspecific treponemal test (STFT) or fluorescent treponemal antibody absorption test (FTA-ABS)

- Cytologic detection (Tzanck smear) is not sensitive and should not be relied upon

- Growth of HSV in culture with acridine staining is gold standard

- Rapid plasma reagin (RPR) and venereal disease research laboratory (VDRL) sensitivity is 6% in primary syphilis, 100% in secondary, and over 95% in tertiary syphilis

- Must confirm with a specific treponemal test

- Excellent for early syphilis

- Positive for life
## General Measures

- **Screen for co-infection including HIV**
- **Educate for prevention of transmission**
- **Screen partners**

### Differential Diagnosis

### Diagnostic Procedures/Surgery

- **Specialized tests** are required for visualization of dark-staining Donovan bodies in sample

### Pathologic Findings

- **Screen partner**
- **Educate for prevention of transmission**
- **Screen for coinfection (including HIV)**

### Nonulcerative STDs

- **Genital ulcer: Other causes**
- **Genital ulcer mnemonic (CHISEL)**
- **Questionable utility**: Not validated

### Imaging

- **N/A**

### Medication

- **First Line**
  - HIV: [Abillice](https://www.gilead.com) 400 mg PO TID for 7–10 days, or tamsulosin 250 mg PO TID for 7–10 days (SJA)
  - Chlamydia: Azithromycin 1 g PO in 1 dose or doxycycline 200 mg IM in 1 dose
  - Syphilis: Primary—Benzathine penicillin G 2.4 million units IM in 1 dose  
    - Latent—Early—Benzathine penicillin G 2.4 million units IM once. Late—Benzathine penicillin G 2.4 million units IM weekly × 3 wk
  - Tertiary—Neurosyphilis—Benzathine penicillin G 2.4 million units IM weekly × 3 wk
  - Syphilis—denosumab crystalline penicillin G, 3–4 million units IM q4h for 10–14 days
  - Granuloma Inguinale: Doxycycline 100 mg PO BID for 21 days or until all lesions are healed
  - LGV: Doxycycline 100 mg PO BID for 3 wk
  - Gonorrhea: Ceftriaxone 250 mg IM in 1 dose, or ofloxacin 400 mg PO in 1 dose; also treat Chlamydia
  - Chlamydia: Azithromycin 1 g PO in 1 dose or doxycycline 100 mg PO BID for 7 days
  - Trichomonas: Metronidazole 2 g PO 1 dose
  - Genital warts (condyloma): Ablation with laser, electrocautery, or cryotherapy
  - HIV: Kaposi sarcomas
  - Genital ulcers: Ablation with electrocautery, electrosurgery, or surgery
  - HIV: Medical management portends long survival
  - HSV: Outbreaks reduced by prophylactic therapies
  - Many STIs cured with treatment

### Follow-up

- **Patient Monitoring**
  - Screen nonpregnant females <25 yr old for gonorrhea/chlamydia. Screen nonpregnant females with risky behavior for gonorrhea/chlamydia.

### Patient Resources

- CDC: [http://www.cdc.gov/std](http://www.cdc.gov/std)

### CLINICAL/PEARLS

- **When treating gonorrhea treat for chlamydia as these often coexist.**
- **HIV vaccine recommended for Either HIV vaccine is recommended by the CDC for 11–12-year-old girls. Quadrivalent HPV vaccine is recommended for 11–12-year-old boys. Start series at age 9 years.**
- **Vaccination is also recommended for 13–16-year-old females and 13–21-year-old males who have not completed the vaccine series. Quadrivalent HPV vaccine may be given to 22–26-year-old males and is routinely recommended for both men who have sex with men (MSM) and immunocompromised persons aged 22 through 26 years.**
- **Immunization may lead to urethral stricture in men.**
SICKLE CELL DISEASE, UROLOGIC CONSIDERATIONS

Philip J. Dorsey, Jr., MD, MPH
Benjamin R. Lee, MD, FACS

DESCRIPTION

Sickle-cell SC disease is a chronic hemoglobinopathy transmitted genetically and marked by severe chronic hemolytic anemia and periodic acute painful episodes.

Genetics

SC trait (heterozygote) usually asymptomatic
SC disease: Inheritance of 2 alleles, all RBCs contain HbS tetramer: The deoxygenated state polymerizes
Several haplotypes; allelic with β-thalassemia
Allele is on chromosome 11
Autosomal codominant inheritance pattern

Prevalence

25–30% of Western Africans have SC trait
8–10% of African Americans have SC trait
Prevalence estimated at 8% of African Americans
∼1:500 African American births
1:1,000 Hispanic American births

RISK FACTORS

Renal papillary necrosis due to ischemia; may cause secondary infection or obstruction
Hematuria is due to chronic papillary infarctions
Decreased renal concentrating ability is common
SC trait (heterozygote) usually asymptomatic

ASSOCIATED CONDITIONS

Anaemia
Anemia
Hepatitis C and HIV (increased risk for these and other transfusion-associated infections)
Priapism
Renal medullary carcinoma
Hypothyroidism (Urine with low specific gravity)
Urinary tract infections

GENERAL PREVENTION

Avoid situations that precipitate sickling episodes
Pathologic Findings

Peripheral blood smear: Presence of sickled or deformed RBCs

PHYSICAL EXAM

HTN is unusual.
Nocturnal enuresis
Timing of sexual maturation (delayed puberty)

ASSOCIATED CONDITIONS

Anemia
Acute papillary necrosis

DIAGNOSIS

HISTORY

Prior episodes of SC complications and outcomes
Timing of sexual maturation (delayed puberty)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Complete blood count (CBC). Note degree of anemia
Peripheral blood smear. Presence of sickled or deformed RBCs with high reticulocyte count
Hb electrophoresis: Types and percentage of Hb present

Lab

SC prep: Rapid determination of SC disease vs. trait vs. normal. Check fetal Hb level
Urinary analysis: Hematuria, proteinuria, or infection
Urinal culture: Infection if indicated by urinary analysis or symptoms
Serum creatinine
Monitor for renal insufficiency, and calculate GFR as needed. The creatinine clearance may overestimate the GFR.

TREATMENT

GENERAL MEASURES

Hematuria (see Section I topic)
Priapism (see Section I topic)

DIAGNOSTIC PROCEDURES/SURGERY

CT urogram using low-osmolar contrast, as indicated for hematuria
Ureteroscopy: For hematuria as indicated

IMAGING

CT urogram using low-osmolar contrast, as indicated for hematuria
– May not be useful in progressive renal insufficiency
– May not be useful in progressive renal insufficiency
– May not be useful in progressive renal insufficiency

PHYSICAL EXAM

HTN is unusual.
Nocturnal enuresis
Timing of sexual maturation (delayed puberty)

ASSOCIATED CONDITIONS

Anemia
Acute papillary necrosis

DIAGNOSIS

HISTORY

Prior episodes of SC complications and outcomes

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Complete blood count (CBC). Note degree of anemia
Peripheral blood smear. Presence of sickled or deformed RBCs with high reticulocyte count
Hb electrophoresis: Types and percentage of Hb present

Lab

SC prep: Rapid determination of SC disease vs. trait vs. normal. Check fetal Hb level
Urinary analysis: Hematuria, proteinuria, or infection
Urinal culture: Infection if indicated by urinary analysis or symptoms
Serum creatinine
Monitor for renal insufficiency, and calculate GFR as needed. The creatinine clearance may overestimate the GFR.

TREATMENT

GENERAL MEASURES

Hematuria (see Section I topic)
Priapism (see Section I topic)
SICKLE CELL DISEASE, UROLOGIC CONSIDERATIONS

MEDICATION

First Line

- Simple transfusion:
  - Transfusion performed to increase proportion of RBCs with normal Hb to decrease sludging
  - Blood transfusion performed less frequently than in the past because of risks of exposure to antigens
- Antibiotics: As needed for infections
- Hematuria:
  - Divided with IV hydration is standard
  - Alkalization decreases sludging and control persistent and threatening hematuria, but can cause clot formation in the urinary tract
- Persistent or threatening hematuria may rarely necessitate nephrectomy
- High-dose uro in selected cases
- Priapism (see Section 4.1 "Priapism").
  - Prompt corporal irrigation to induce detumescence and remove old clotted blood
  - Use an adrenergic medication for corporal injection to decrease infusate for detumescence
  - Impotence due to fibrosis can be managed with penile prosthesis after 6 mo
- Delayed sexual maturation:
  - Caution supplemented of testosterone
  - Second Line

Surgery/Other Procedures

May be needed in the acute setting for priapism
- Radiation Therapy

NA

Additional Therapies

- Follow-up and monitoring by hematologist
- Folic acid and penicillin in pediatrics

Genetic counseling

Complementary & Alternative Therapies

NA

ONGOING CARE

PROGNOSIS

Several factors aside from genetic inheritance determine prognosis, including frequency, severity, and nature of specific complications.

COMPLICATIONS

- Nephropathy:
  - Renal insufficiency
  - Vas-class renal medulla secondary to hyperosmolality, inducing RBCs sludging
  - Progressive cortical infarction leads to CRF, average age of onset is 23 yr
  - Hypertension: inability to maintain systolic urine in the face of dehydration or vasopressin
  - Usually associated with renal insufficiency, able to dilute urine
  - Associated impairment of K excretion
  - Renal biopsy:
  - Fibrotic and segmental glomerulosclerosis, membranous glomerulopathy, or MPGN
  - Proteasia may progress to full-blown nephrotic syndrome

- Hematuria:
  - Microscopic or gross hematuria, mechanism unknown. Source rarely identified, possibly due to papillary necrosis
  - Usually unilateral (left-sided)
  - May be female
  - Usually rectum with contraceptive (e.g., sperm, condoms, hydration) with 50% recurrence
  - Associated with nephrotic syndrome
  - Papillary necrosis:
  - Due to medullary ischemia from sludging in vasa recta (see in 40% of patients with SCD)
  - Radiologic diagnosis: can be difficult due to poor concentrating ability of kidneys
  - Can cause hematuria
  - Can obstruct, if sloughed papilla blocks the UPJ or ureter
  - Priapisms:
  - Affects ~66% of SC disease patients
  - 2 age peaks: onset usually after puberty is 5–13 yr, then at 21–29 yr
  - Initiating factors: Nocturnal penile tumescence and sexual arousal
  - Typically, biopsoral involvement
  - Pathophysiology: Engagement and sludging of the corpora, with no outflow and low flow
  - Major risk in fibrosis and subsequent impotence; children have greater chance of recovery and subsequent erectile function
  - Impotence:
  - Fibrosis from recurrent episodes of priapism
  - Delayed sexual maturation:
  - Primary hypogonadism, due to testicular ischemia or infarction, hypothyroidism, or hypothalamic insufficiency
  - Correlates with severity of sickle disease
  - Infertility:
  - Complication of hypospermatism and direct testicular insult by ischemia or infarction
  - UT:
  - Usually escherichia coi, or other gram-negative bacteria
  - Can lead to more serious infections or bacteremia

PRO Academy 

- Incomplete distal RTA type I (from progressive medullary infarction
  - Inability to lower urine pH to <5
  - Compensatory hyperchloremic metabolic acidosis in SC disease and renal insufficiency
  - Not associated with nephrotic

- Acute urinary retention:
  - Related to acute, painful SC, transient, resolves with resolution of the acute episode
  - Renal medullary carcinoma:
    - Median age 13 yr
    - High mortality

Follow-Up

Patient Monitoring

- Renal function over time
- Regular follow-up

Patient Resources

Clinical/Surgical Pearls

Urologic complications are common in SC disease.
SPERMATIC CORD MASS AND TUMORS
Nima Baradaran, MD
James S. Rosof, MD

DESCRIPTION
• The spermatic cord extends from the internal inguinal ring to the testicle, passing through the inguinal canal.
• Cord structures consist of vas deferens, internal and external spermatic arteries, artery to the testicle, pampiniform plexus, lymphatic, nerves, investing layer of fascia, and cremaster muscle.
• Considered paratesticular tissue.
• Masses or swelling can be cystic or solid:
  - Most cystic (75-80%)
  - Usually asymptomatic
  - Most solid spermatic cord masses are also benign.

EPIDEMIOLOGY
Incidence
Variates by type (see Pathophysiology).
Prevalence
Variates by type (see Pathophysiology).

RISK FACTORS
Variates by type (see Pathophysiology).

GENETICS
Variates by type (see Pathophysiology).

PATHOPHYSIOLOGY
• Cord mass can arise from cord contents or from structures above or below the cord:
  - Generally noncute and benign
  - Most common malignant tumors are sarcoma
  - Varicocele
  - Hydrocele
  - Generally nonacute and benign
  - Cord mass can arise from cord contents or from structures above or below the cord.
  - Considered paratesticular tissue
  - Rare congenital anomaly from abnormal closure of the processus vaginalis
  - Palpable, grade II: Palpable without Valsalva maneuver.
  - Generally nonacute and benign
  - May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
  - Painful groin mass contiguous with the cord structures that transilluminates.

Hydrocele:
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.

Varicocele:
• Enlarged, tortuous spermatic veins above the testis; most common on the left side.
• Varicocele:
  - Rare inflammation of spermatic cord, epididymis, and paratesticular soft tissue, from muscle, adipose, or connective tissue
  - More common in young, sexually active males
  - Presents as TBJ, epithelial, difficult to differentiate from acute epididymoorchitis
  - Usually secondary to infection of epididymis via direct extension.
  - Scrotal:
    - Systemic granulomatous disease, increased intestinal absorption of calcium, hyperparathyroidism, and hypercalcemia
  - Varicocele:
    - Inflammation of spermatic cord secondary to severe epididymitis or due to trauma
  - Flail Harlequin:
    - Caused by Wuchereria bancrofti, often with a thickened spermatic cord and epididymis
  - Undescended testicle
  - Retroperitoneal tumors:

ASSOCIATED CONDITIONS
• Renal tumor invading renal vein or retroperitoneal mass compressing right gonadal vein with ischemia.
• Spasmatic cord:
  - Cloudy fluid and sperm filled cyst arising from epididymal tubules.

HISTORY
• Patients present with symptoms or asymptomatic mass with or without swelling.
• Most masses are painless or at onset.
• Presence or absence of pain does not differentiate benign or malignant mass.
• Scrotal elevation may provide relief.
• Recumbent position may resolve mass and pain in varicocele and communicating hydrocele.
• History of cryptorchidism is important.

ALERT
• Always rule out torsion of cord if pain is acute.

PHYSICAL EXAM
• Examine patient in warm room in both upright and supine positions.
• Cord mass can be palpated in the inguinal region or the upper scrotum.
• Palpate mass with thumbs and 1 to 2 fingers of both hands and note character (hard, firm, cystic).
• Transillumination signifies cystic mass: cystic mass may not transilluminate if thick wall, chronic inflammation, or blood present.
• Spermatic cord can be followed to the internal inguinal ring by palpation.
• Verify both testicles present in scrotum.
• The vas deferens can be felt in the scrotum by 1st encircling the cord with the fingers and allowing small amounts of cord to pass through.
• Testicular biopsy may be appropriate.
• Palpation can determine superior and inferior extent of mass.
• Testicular tissues may be atrophic.

DIAGNOSIS

BASICS
• swims toward synovial and parietal layers of tunica vaginalis.
• Palpable, grade II: Palpable without Valsalva maneuver.
• Generally nonacute and benign
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Palpable, grade II: Palpable without Valsalva maneuver.
• Generally nonacute and benign
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Palpable, grade II: Palpable without Valsalva maneuver.
• Generally nonacute and benign
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Palpable, grade II: Palpable without Valsalva maneuver.
• Generally nonacute and benign
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.
• Painful processus vaginalis causes collection of peritoneal fluid between the vaginal and parietal layers of tunica vaginalis.
• May cause infertility: likely increasing scrotal temperature, impairing spermatozoogenesis.

- – Communicating hydrocele with hernia:
- – Explore all solid masses for malignancy:
- – Inguinal incision; testis is delivered and inspected
- – Communicating hydrocele with hernia:
- – Explore all solid masses for malignancy:
- – Inguinal incision; testis is delivered and inspected
- – Communicating hydrocele with hernia:
- – Explore all solid masses for malignancy:
- – Inguinal incision; testis is delivered and inspected

GENERAL MEASURES
- Distinguish tests and epididymitis (physical exam, transillumination, social DoS).
- Most cutaneous masses do not need treatment.
- Investigate pain as presenting feature; sarcoma is often misdiagnosed as inflammatory lesion.

MEDICATION

First Line
- Anti-TB short course for 6–9 mo for TB (tuberculoma) in spermatic cord

Second Line
- N/A

SURGERY/OTHER PROCEDURES
- Surgical Excision: if choice of procedure
- Elective exploration of asymptomatic contralateral inguinal

– Biopsy to confirm diagnosis
– Early control of cord at internal ring
– Inguinal incision; testis is delivered and inspected
– Standard tests: volume measurements are
– Explore solid masses for malignancy:
– Inguinal incision; testis is delivered and inspected

ADDITIONAL TREATMENT
Radiation Therapy
- Retroperitoneal lymphadenopathy with adjacent
- radiation or chemotherapy indicated for malignant

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

PEARLS
- Pain may be attributed to emergencies such as
torsion,
- Ultrasound is a valuable diagnostic tool.

PROGNOSIS
- Excellent for benign lesions

COMPLICATIONS
- Risk of infertility in varicocele

FOLLOW-UP
- Patient Monitoring
- None for benign masses.
- Liposarcoma, leiomyosarcoma, and
- rhabdomyosarcoma may recur; closely monitor
- Ager 2 if it does not

Patient Resources
- N/A

SPERMATOCELE
Irvin H. Hirsch, MD
Leonard G. Gomella, MD, FACS

**PATHOPHYSIOLOGY**
- Main concern is usually that of confusion with a true testicular mass.
- Precise mechanism is unknown.
- Cystic dilatations of tubules of the epididymis
- The efferent ductules in the head of the epididymis
- The distinction between a spermatocele and an epididymal cyst is based on size, epididymal cystic masses >2 cm are spermatoceles
- Spermatoceles are always located superior to the testis and are palpable as distinct from the testis, which differentiates them from hydroceles
- Spermatocele generally range in size from 2 to 5 cm
- Trauma and inflammation may result in obstructed efferent ductules or epididymal tubules, resulting in a dilated spermatocele
- No effect on fertility
- Most are idiopathic
- Most <5 cm in size

**ASSOCIATED CONDITIONS**
- Epididymal obstruction may rarely be present
- Prior vasectomy
- High association with tubular ectasia of the rete testes

**DIAGNOSIS**

**HISTORY**
- Typical presentation is a painless, asymptomatic, intratesticular mass found on testicular self-exam or on routine office exam.
- Occasionaly may present with orchialgia or scrotal heaviness
- No associated urinary symptoms

**PHYSICAL EXAM**
- Palpation shows a smooth, soft, nontender mass at the head (caput) of the epididymis
- Less palpable posterior to the testis but is distinct from testis
- A cystic mass above the testis is usually demonstrated on scrotal transillumination

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urine analysis

**Imaging**
- Scrotal US is diagnostic
  - Lesion is hypoechogenic with posterior acoustic enhancement
  - May have internal echoes
- MRI if US is indeterminate

**Differential Diagnosis**
- Adenoma tumor of the epididymis
  - Most common solid tumor of the epididymis
  - Enlarged epididymis
- Epidermoid cyst
  - Most common solid tumor of the epididymis
  - Hydrocele, the other common cystic lesion is devoid of spermatozoa
- Fibromuscular wall lined by cuboidal epithelium

**BASICS**

**DESCRIPTION**
- Spermatocele is a benign, fluid-filled cystic mass most often in the head (caput) of the epididymis
- The spermatocele can occur in other areas of the epididymis, rete testis, or along the vas deferens
- Sometimes referred to as a “spermatic cyst” or an “acquired epididymal cyst.”
- Clinically, spermatocele is differentiated from a hydrocele in that the spermatocele may contain viable or nonviable spermatozoa.
- Usually not a cause of epididymal obstruction
- Also called an epididymal cyst or acquired epididymal cyst in the literature (1)
- Some sources state that the epididymal cyst is congenital and represents the most common epididymal mass.
- The origin of the epididymal cyst is thought to be lymphatic.
- Epididymal cyst fluid does not contain spermatozoa.
- Clinical management is similar, so the differentiation between spermatocele and epididymal cyst may not be significant.

**EPIDEMIOLOGY**
- Incidence
  - Peak incidence in 4th–5th decades
  - Rare in children
  - No racial or ethnic predilection
  - Rare in children
  - Peak incidence in 4th–5th decades

**RISK FACTORS**
- Diethylstilbestrol (DES) exposure in utero
- Inflammation
- VHL syndrome: Von-Hippel Lindau (VHL) syndrome
- Mutations of the VHL suppressor gene on 3p
- VHL syndrome
  - Increased incidence of epididymal cysts and papillary cystadenomas of the epididymis
  - Clinical management is similar, so the differentiation between spermatocele and epididymal cyst may not be significant
  - On US, most common appearance is 15–20-mm solid mass with small cystic components
  - Epidermoid Epididymis/Epiploicae
    - Acute, very tender on exam
    - Chronic, may have secondary calcification
    - Common cause of epididymal pain

**ASSOCIATED CONDITIONS**
- High association with tubular ectasia of the rete testis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urine analysis

**Imaging**
- Scrotal US is diagnostic
  - Lesion is hypoechogenic with posterior acoustic enhancement
- MRI if US is indeterminate

**DIFFERENTIAL DIAGNOSIS**
- Adenoma tumor of the epididymis
  - Most common solid tumor of the epididymis
  - Enlarged epididymis
- Epidermoid cyst
  - Most common solid tumor of the epididymis
  - Hydrocele, the other common cystic lesion is devoid of spermatozoa
- Fibromuscular wall lined by cuboidal epithelium

**BASICS**

**DIAGNOSIS**

**HISTORY**
- Typical presentation is a painless, asymptomatic, intratesticular mass found on testicular self-exam or on routine office exam.
- Occasionaly may present with orchialgia or scrotal heaviness
- No associated urinary symptoms

**PHYSICAL EXAM**
- Palpation shows a smooth, soft, spherical nontender mass at the head (caput) of the epididymis.
- Less palpable posterior to the testis but is distinct from testis
- A cystic mass above the testis is usually demonstrated on scrotal transillumination

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Urine analysis

**Imaging**
- Scrotal US is diagnostic
  - Lesion is hypoechogenic with posterior acoustic enhancement
  - May have internal echoes
- MRI if US is indeterminate

**DIFFERENTIAL DIAGNOSIS**
- Adenoma tumor of the epididymis
  - Most common solid tumor of the epididymis
  - Enlarged epididymis
- Epidermoid cyst
  - Most common solid tumor of the epididymis
  - Hydrocele, the other common cystic lesion is devoid of spermatozoa
- Fibromuscular wall lined by cuboidal epithelium
Surgey should be deferred in men seeking fertility
Ligation of spermatocele at its stalk
Performed by magnified or microsurgical dissection
Spermatocelectomy is elective and indicated for
Supportive care is usually sufficient:
Most do not require treatment unless symptomatic.
Varicocele
TB of the epididymis
Sperm granuloma:
Sarcoid
Polyorchidism
Papillary cystadenoma:
Malignant epididymal tumor:
Epithelial and transitional cell cancers
Gastrointestinal tumors: Pancreatic, rectal, colon
Gynecologic cancers: Cervical, uterine
Melanoma
Adenocarcinomas: Cervix, breast, prostate, bladder
Lymphomas: Non-Hodgkin lymphoma, Hodgkin disease
Malignant germ cell tumors: Testicular germ cell tumors
Seminoma, non-seminomatous germ cell tumors
Chemotherapy: For systemic disease
Radiotherapy: For localized disease
Orchidectomy: For local disease
Prognosis: 5-year survival rates
Additional treatment
Surgical therapy: Epididymectomy, sperm cystectomy
Non-surgical therapy: Vasectomy, intratesticular chemotherapy
Future fertility
Testicular biopsy: Biopsy of the testis to evaluate spermatogenesis
Testicular self-exam: A method to detect testicular masses
Sperm banking: Storing sperm for future use
Sperm retrieval: Technique to retrieve sperm from infertile men
Sperm injection: Intrauterine insemination, intracytoplasmic sperm injection
Prognosis
Typical cases
Non-seminomatous germ cell tumors
Seminoma
Other tumors
Close follow-up
Surgical management
Radiation therapy
Chemotherapy
Fertility preservation
Orchidectomy
Adjuvant therapy
Follow-up
Patient monitoring
Patient resources
Additional reading
Clinical/surgical pearls
• A common pitfall is the failure to distinguish between hydrocele and spermatocele preoperatively.
• Spermatoceles are always located superior to the testis and are palpable as distinct from the testis, which differentiates them from hydroceles.
• Ideal surgical approach: Incise the tunica albuginea testis to maintain the spermatocele definition throughout its excision.

Additional treatments
• Transcutaneous aspiration with or without sclerotherapy:
  • Agents used have included tetracycline, fibrin glue, phentol, talc powder, and others
  • Not usually recommended due to high recurrence rate and chemical epididymitis
  • Spermatocele aspiration may provide a sperm source for azoospermic men treated by IVF or ICSI

Additional therapies
N/A

Prognosis
• Most require no intervention and do not lead to epididymal obstruction.
• Recurrence rate is low postoperatively.

Complications
• Orchalgia
• Concern for cancer
• Postoperative spermatocele
• Vascular injury during spermatocelectomy causing testicular atrophy
• Infection
• Epididymal obstruction: Very concerning in cases of bilateral spermatocele surgical repair. Some authors recommend sperm cryopreservation in this setting

Follow-up
• Periodic scrotal self-exam
• Sperm count and motility
• Continued testosterone self-exam

Ongoing care
• Periodic scrotal US if symptoms recur
• Sperm count and motility

References
SPINAL CORD INJURY, UROLOGIC CONSIDERATIONS
Jessica Wetterlin, MD
Derek Matoka, MD

BASICS

DESCRIPTION
- Spinal cord injury (SCI) may result from damage to the spinal column secondary to trauma, vascular injury, infection, or disc prolapse
- SD can impact lower urinary tract and sexual function and varies based on level and completeness of injury
- Upper and lower urinary tract dysfunction due to SCI can lead to significant morbidity and mortality
  - Increased risk for renal failure, UTI (urinary tract infection), small/badder candidiasis, and malignancy

EPIDEMIOLOGY
- Incidence
  - 40 cases per million in US; 12,000 new cases per year

DESCRIPTION
- Derek Matoka, MD

ASSOCIATED CONDITIONS
- Bladder wall thickening and fibrosis common
- Pathologic Findings
- Diagnostic Tests & Interpretation

DIAGNOSIS

HISTORY
- Onset, duration, etiology of injury
- Voiding symptoms
- - Incontinence or obstructive
- - Inconce: Stress, urge, overflow
- Method of urinary management
- Voluntary voiding, closed intermittent catheterization (OIC), indwelling catheter or urethral catheter

PHYSICAL EXAM
- Temperature, blood pressure
- Palpable flank mass/tenderness
- Suprapubic fullness: Distended bladder
- Evaluate instincion, spontaneity or with stress maneuvers
- GU exam for testicular or prostate abnormality
- Complete Neurologic exam: Sensation, tone, and bladder activity

GU exam for testicular or prostate abnormality
- Evaluate instincion, spontaneity or with stress maneuvers
- Complete Neurologic exam: Sensation, tone, and bladder activity

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Blood studies:
    - Serum chemistry: Basic metabolic panel (BMP) (assess renal function and acidosis), CBC
    - Urinalysis
  - Imaging:
    - Renal US (ultrasound): To screen for calculi, urolithiasis episodes, interventions, calculus
    - VCUG (voiding cystourethrogram):
      - Trabeculation, diverticulum, incomplete emptying, vesicoureteral reflux
      - Nuclear medicine renal scan:
        - Performed to evaluate for compromised function or presence of obstructive element

Diagnostic Procedures/Surgery
- PVR: To ensure complete bladder emptying
- Video urodynamics: Essential to assess and follow bladder and urodynamic dysfunction
- Video urodynamics: Essential to assess and follow bladder and urodynamic dysfunction

Diagnosis
- Injury
  - Intervertebral disc disease
  - Malignancy (metastasis)
  - Spinal cord vascular disease
  - Traumatic
  - Ventral body injury

DIFFERENTIAL DIAGNOSIS
- Intervertebral disc disease
- Malignancy (metastasis)
- Spinal cord vascular disease
- Traumatic
- Ventral body injury
TREATMENT

GENERAL MEASURES
- Goal of treatment: Optimize intravesical bladder pressures to protect upper urinary tract
- Spontaneous voiding with continence
- Indwelling catheterization should be avoided when possible to avoid complications (urethral strictures, UTI, calciﬁcation, malignancy)
- Indwelling urethral catheter or suprapubic tube (SPT)
- Immobile self-catheterization: Most effective treatment, requires manual dexterity
- If unable to self-catheterize urethra
- Male: External catheter, cutout obstruction procedure, urinary diversion, or creation of continent catheterizable stoma
- Female: Urinary diversion or creation of continent catheterizable stoma
- Incontinence between catheterizations may suggest elevated intravesical pressure due to poor compliance or DO
- Reduce storage pressure. Increase frequency of catheterization, anticholinergics, or augmentation cystoplasty
- Lower urinary tract that cannot be reconstructed require urinary diversion with or without continent ileovesicostomy
- Incontinent urostomy
- Continent urinary reservoir

MEDICATION
First Line
- Anticholinergics improve urinary storage pressure and decrease involuntary contraction
- Oxybutynin 5 mg PO BID-TID
- Tolterodine 2 mg PO BD, others
- α-adrenergic blockers: Decrease internal sphincter function, lower voiding pressures, ineffective for DO
- Agents include: doxazosin 1–8 mg PO QD, tamsulosin 1–10 mg PO QHS, tamsulosin 0.4 mg PO QD

Second Line
- Botulinum toxin injected into detrusor

SURGERY/OTHER PROCEDURES
- Spina bifida requires external catheter
- Augmentation cystoplasty: Use of internal segment to enlarge the bladder, increasing bladder volume to decrease intravesical pressure
- Usually requires clean intermittent catheterization (CIC)
- Neuropathy
- Useful for those unable to perform CIC
- Social reeducation
- Deafferentation with dedenervation abolishes spontaneous detrusor contraction, improving urinary storage
- Nerve root stimulation allows for control over detrusor contraction

ADDITIONAL TREATMENT
Radiation Therapy
HIV

Additional Therapies
Sacral nerve root stimulator

Complementary & Alternative Therapies
- Vanillin agents (capsaicin and wakameferon) suppress uninhibited detrusor contraction

ONGOING CARE

PROGNOSIS
- Poor urologic care improves morbidity, mortality, and quality of life in SCI individuals
- Early data suggested renal disease was major cause of death in the paraplegic patient. However, more recent data has revealed that pneumonia, sepsis, heart attack, accidents, and suicides are now leading causes of mortality (2)

COMPLICATIONS
- Urosepsis (3)
- Ulceration
- Due to urinary tract, chronic infection, acidosis associated with immobility, bladder calculi related to chronic indwelling catheters
- Upper urinary tract deterioration
- Hydroureteronephrosis due to elevated intravesical pressure
- Lower urinary tract deterioration
- Detrusor hypertrophy, decreased compliance
- Urinary-erosion, fistula with chronic catheterization

Autonomic dysreflexia
- Can occur with SCI at T6 level or higher with complete/incomplete spinal cord lesions
- Triggered by a noxious stimuli below the level of the lesion, bladder and bowel dysfunction are the most common causes
- Unopposed sympathetic activity results in vasoconstriction and HTN (hypertension)
- HTN sensed by baroreceptors in carotid and aortic arch activating parasympathetics above lesion to counter the sympathetic response. However, the SCI inhibits parasympathetics activity below the level of the lesion
- Signs and symptoms include HTN, headache, bradycardia, flushing, diaphoresis, blurred vision
- Treatment: Remove offending stimuli
- Address HTN with rapid onset/short duration agent (nifedipine, captopril, hydralazine)

Detrusor hypertrophy
- Associated with chronic catheter
- Depression
- Skin complications (related to incontinence)

Felty’s Syndrome
- Urologic complications (related to infection)

FOLLOW-UP

Patient Monitoring
- UTS screening: Routine urine cultures are unnecessary in healthy, asymptomatic individuals
- UDS: Completed periodically. However, no consensus exists regarding frequency. Obtain UDS after resolution of spinal shock and every 5 yr in stable patients. If a change in bladder-related symptoms (incontinence) is noted, UDS should be repeated to evaluate for change in bladder dynamics
- UTI: Useful, noninvasive screening tool to monitor upper and lower tracts
- Recommended initially and annually for 5–10 yr, then every other year

ADDITIONAL READING
- See Also (Topic, Algorithm, Media)
- Autonomic Dysreflexia
- Bladder Anuria (Detrusor Areﬂexia)
- Detrusor-Sphincter Dyssynergia (DSD)
- Neurogenic Bladder, General
- Neuropathic Detrusor Overactivity (NDO)
- Spinal Cord Injury, Urologic Considerations
- Augmentation
- Urinary-Stomal, Indications and Normal Values

COMMENTS

CLINICAL/SURGICAL PEARLS
- Suprasacral lesions generally result in an upper motor neuron deﬁcit with NDO
-Sacral lesions generally produce a lower motor neuron deﬁcit with resulting detrusor areﬂexia
- UDS should be obtained at least 6 wk after injury and repeated when appropriate

REFERENCES
STRESS URINARY INCONTINENCE, FEMALE
Nima Baradaran, MD
Samuel Walker Nickles, MD
Eric S. Rovner, MD, FACS

BASICS

DESCRIPTION
- Stress urinary incontinence (SUI) is subjectively defined by the International Continence Society as the “true complaint of involuntary leakage on effort or exertion, or on sneezing or coughing” (1)
- Urinary incontinence (UI) should be further described by specifying: Type, frequency, severity, precipitating factors, social impact, effect on hygiene and quality of life, the measures used to contain the leakage and whether or not the individual seeks or desires help because of urinary incontinence (1)

EPIDEMIOLOGY
Incidence
Annual incidence of any type of new UI ranges from 3 to 11% and increases with age, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Prevalence
~30% of women aged 30 to 60 have urinary incontinence, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Significant variation is seen in specific populations, eg, incontinence, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Incidence
Annual incidence of any type of new UI ranges from 3 to 11% and increases with age, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Prevalence
~30% of women aged 30 to 60 have urinary incontinence, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Significant variation is seen in specific populations, eg, community dwelling vs. long-term facility occupants, and nulliparous vs. postpartum females.

RISK FACTORS
Aging, obesity, smoking, pregnancy, and child birth

Genetics
Deficient collagen structures

PATHOPHYSIOLOGY
Anteriorly: Weakness of urethral supportive structures (vaginal wall and surrounding connective tissue) leads to hypermobility and loss of urethral compression (1)

Intrinsic sphincter deficiency: Loss of intrinsic urethral closure, coaptation, and function

Neurogenic: Rarely, loss of spinal sympathetic reflex and/or pudendal nerve efferents leading to relaxation of the external and intrinsic closure forces of the urethra.

ASSOCIATED CONDITIONS
- Chronic cough, COPD, obesity
- Pelvic organ prolapse (cystocele, rectocele) and/or anal incontinence
- 40% of women with urethral sphincter incompetence will have a cystocele
- Occult incompetence: Urethral sphincteric incompetence masked by the presence of pelvic prolapse

GENERAL PREVENTION
See treatment

DIAGNOSIS

HISTORY
- Subjective characterization of UI (aggravating factors)
- Duration of symptoms
- Impact on life
- Diaphoresis vs. nocturnal UI
- Urinary frequency, urgency, nocturia
- UI history
- Pad use
- Past medical/surgical history
- Neurologic (Parkinson, MS, back surgery, etc.)
- Medical conditions (DIAB, dementia, etc.)
- Radiation and trauma
- Gynecologic history (parity, hormonal status)
- Previous pelvic surgery
- Medications (psychotropics and diuretics)

PHYSICAL EXAM
- Cough stress test to be negative.

DIAGNOSTIC TESTS & INTERPRETATION

BASICS

Lab
- Routine renal function evaluation unnecessary
- Pad test
- Postvoid residual measurement
- Voiding diary
- Quality of life questionnaires
- Urodynamics
- Urodynamics indicated especially in patients who have failed previous pelvic floor reconstruction or with mixed incontinence, urinary urgency, or obstructive symptoms, and in those who have elevated PVRs or neurologic disease

Pathologic Findings
- Sphincter muscle deficiency is the main pathology.

DIFFERENTIAL DIAGNOSIS

- Enuresis means any involuntary loss of urine. If it is used to denote incontinence during sleep, it should always be qualified with the adjective “nocturnal”
- Richter: Vesicovaginal, rectovaginal
- Mixed urinary incontinence (MUI) is the complaint of involuntary leakage associated with urgency and also with exertion, effort, sneezing, or coughing
- Neurogenic bladder (CVD and spinal cord lesions)
- Pelvic organ prolapse
- Polyuria/polydipsia
- Potentially reversible conditions (DIAPERS):
  - Drugs
  - Infection
  - Atonic vaginitis
  - Psychological (depression, delirium, dementia)
  - Endocrine (hyperglycemia, hypercalcemia)
  - Restricted mobility
  - Fluid intake
  - Situation specific: eg, the report of incontinence during sexual intercourse, origgie incontinence
  - Urethral abnormalities (diverticulum)
  - Urge vs. stress vs. overflow incontinence
  - Urethral incontinence: Involuntary leakage accompanied by or immediately preceded by urgency
  - Urinary leakage may need to be distinguished from sweating or vaginal discharge
  - Urethral fist infection
  - Vaginal vaulting

- Cystoscopy in the presence of urinary urgency, hematuria, UTI, or other irritative symptoms, particularly if they have previously undergone a previous anti-incontinence procedure, pelvic radiation, or pelvic prolapse repair

- Urodynamics indicated especially in patients who have failed previous pelvic floor reconstruction or with mixed incontinence, urinary urgency, or obstructive symptoms, and in those who have elevated PVRs or neurologic disease
STRESS URINARY INCONTINENCE, FEMALE

TREATMENT

GENERAL MEASURES
- Initial therapy includes behavioral modification and pelvic floor exercise
- Lifestyle modifications
- Weight loss, smoking cessation, moderation of fluid intake, caffeine and/or alcohol

ADDITIONAL TREATMENT
- Pelvic floor muscle training (PFMT)
- Transurethral injectable bulking agents

SURGERY/OTHER PROCEDURES
- In rare cases an α-adrenergic receptor antagonist (phenylpropanolamine) or tricyclic antidepressant (imipramine) may be utilized but this is an off-label use
- Duloxetine is a serotonin and norepinephrine reuptake inhibitor approved for major depression and is approved for treatment of SUI in Europe but not in US

Medication
- Inhibits detrusor contractions
- Strong pelvic floor contraction increases intra-abdominal pressure
- Patient compliance and periodic reinforcement are essential
- Timed voiding
- Fluid and dietary management
- Patient education and periodic reinforcement are essential
- Pelvic floor muscle training (PFMT)
- Vaginal cones and weights
- Biofeedback: Helps patients identify and isolate correct pelvic muscles
- Pelvic floor electrical stimulation
- Magnetic therapy
- Wire- or extravesical and intravaginal support and occlusive devices (pessaries, plugs, urethral inserts, etc.)

Complications
- Untreated SUI may result in skin rash and chronic irritation
- Vaginal, urethral, and intravesical erosion of the synthetic suburethral sling
- Complications of sling procedures include:
  - Urinary retention following stress incontinence
  - Dyspareunia
  - Voiding dysfunction (due to obstruction), UTI, pain, and dyspareunia
  - Vaginal, urethral, and intravesical erosion of the intravesical and intravaginal support, voiding dysfunction (due to obstruction), UI, UTI, and dyspareunia
  - Vascular injury or intestinal perforations are rare and associated with slings, as well as open abdominal approaches

Follow-up
- Patient Monitoring
- Conservative management requires regular reinforcement and education

Patient Resources
- National Association for Continence
- http://www.nafc.org

REFERENCES

Ongoing Care

Additional Reading
- Dmochowski RR, Blaivas JM, Gormley EA, et al. Second Line

Addendum
- Pelvic floor muscle training training versus no treatment, or inactive control treatments, for urinary incontinence in women.

See Also
- Topic, Algorithm, Media
- ICD (International Classification of Incontinence Questionnaire), ICQ-MIUTS
- Incontinence Impact Questionnaire (IIQ-7)
- Incontinence, Urinary, Adult Female
- Pad Test
- SUI (Stress Urinary Incontinence)
- Stress Urinary Incontinence, Female Images

Codes
- ICD9: 593.3 Stress incontinence, female
- ICD10: N39.3 Stress incontinence (female) (male)

Clinical/Surgical Pearls
- It is imperative to distinguish different types of urinary incontinence in female.
- Lifestyle modification and conservative treatment is the 1st step in management.
- Midurethral slings are the standard surgical treatment and are highly effective in properly selected patients.
STRESS URINARY INCONTINENCE, MALE

Jack Matthew Zuckerman, MD
Kurt A. McCammon, MD, FACS

PATHOPHYSIOLOGY

Male continence relies on an intact internal and external urinary sphincter and a compliant bladder for storage of urine.

Internal sphincter:
- Bladder neck and prostate
- Smooth muscle/involuntary
- Internal sphincter
- Detrusor/propulsive

External sphincter:
- Contraction of the external sphincter is required for SUI to be present

Genetics
N/A

DIAGNOSIS

HISTORY

- Incontinence history
- Duration
- Severity (pads, diapers, tissues, etc.)
- The nature of the absorptive device helps with the assessment of the degree of leakage
- Precipitating events (cough, sneeze, etc.)
- Presence/absence of urge symptoms
- Suggests pharmacologic therapy may benefit
- Frequency of urination
- Fluid intake, including use of caffeine, alcohol
- Use of medications such as diuretics or antihypertensive medications
- Neurologic or spinal cord disease or injury
- Voiding diary
- Prior pelvic surgery or other urologic surgery
- Prior pelvic radiation
- Prior anti-incontinence procedures
- AKU symptom score
- ICIQ (International Consultation on Incontinence Questionnaire), ICS-MULTIS

PHYSICAL EXAM

- Abdominal exam
- Urinalysis and urine culture
- Frequency of urination
- Presence/absence of urge symptoms
- Use of medications such as diuretics or antihypertensive medications
- Anticholinergics
- Antidepressant medications
- Anxiety
- Depression
- Unusual abdominal wall pain
- Inguinal hernia
- Spinal deformity
- Skin breakdown or fungal/bacterial infection
- Surgical scars
- Digital rectal exam for assessment of the prostate
- Neurologic or spinal cord disease or injury

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis and urine culture
- PSA if known history of prostate cancer or has had a prostatectomy

Imaging
- Prostate residual urine (PVR) measurement to rule out urinary retention
- Other routine imaging not indicated
STRESS URINARY INCONTINENCE, MALE

**DIAGNOSTIC PROCEDURES/SURGERY**
- Pressure flow studies are helpful to confirm stress incontinence and rule out other complicating factors such as urge incontinence/detrusor overactivity, detrusor underactivity, bladder outlet obstruction, and poor bladder compliance.
- Cystoscopy to rule out uncorrectable anatomic stenosis (most often after radical prostatectomy) or urethral stricture is essential prior to any planned surgical intervention.

**PATHOLOGIC FINDINGS**

**DIFFERENTIAL DIAGNOSIS**
- Stress urinary incontinence
- Urge urinary incontinence: involuntary leakage accompanied by or immediately preceded by urgency
- Mixed urinary incontinence
- Overflow incontinence: urinary retention
- Postvoid dribbling (urine retained in the urethra)
- Stress urinary incontinence: eg, the report of incongruous leakage resulting from sexual intercourse
- Urethral atrophy
- Urinary leakage may need to be distinguished from sweating

**MEDICATION**

- Lifestyle changes: Decreasing certain activities that cause SUI
- Limiting fluid intake
- Efficacious following RP to allow quicker return of continence (7)

**GENERAL MEASURES**

- Pelvic floor physical therapy (eg, “Kegel” exercises)
- Self-reported pad counts are easier to obtain, but not as accurate as a pad weight test.
- Patients may also be followed with 1-hr or 24-hr diaries which can be obtained regularly in the office.

**TREATMENT**

**GENERAL MEASURES**

- Pelvic floor physical therapy (“Kegel” exercises): Efficacious following RP to allow quicker return of continence, though not found to improve overall continence (7).
- May also be used in men with SUI from other causes to strengthen the pelvic floor
- Lifestyle changes: Limiting fluid intake, Decreasing certain activities that cause SUI
- Perineal dressings
- Condom catheter

**MEDICATION**

- Incretin: physical therapy (eg, “Kegel” exercises)
- Effective following RP to allow quicker return of continence, though not found to improve overall continence (7).
- May also be used in men with SUI from other causes to strengthen the pelvic floor
- Lifestyle changes: Limiting fluid intake, Decreasing certain activities that cause SUI
- Perineal dressings
- Condom catheter

**GENERAL MEASURES**

- Pelvic floor physical therapy (“Kegel” exercises): Efficacious following RP to allow quicker return of continence, though not found to improve overall continence (7).
- May also be used in men with SUI from other causes to strengthen the pelvic floor
- Lifestyle changes: Limiting fluid intake, Decreasing certain activities that cause SUI
- Perineal dressings
- Condom catheter

**MEDICATION**

- Anticholinergic agents: Mitralis, Carbidopa
- Skin breakdown
- Candidiasis
- Dermatitis

**DIAGNOSTIC PROCEDURES/SURGERY**

- Prostatectomy history or complications: Report from the Standardization Sub-committee of the International Continence Society.

**ADDITIONAL TREATMENT**

**RADIATION THERAPY**

- N/A

**ADDITIONAL THERAPIES**

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- N/A

**ONGOING CARE**

**PROGNOSIS**

- General speaking SUI is stable or progressive in nature. It is not likely spontaneously resolved.
- PH differs from other causes of SUI in that it has been shown to improve over time. However, a plaque is seen after approximately 2 yr and further improvements are not anticipated (6).
- With surgical treatment, and occasionally medical management, male SUI can be expected to improve dramatically in most cases.

**COMPLICATIONS**

- Urinary incontinence
- Skin breakdown
- Urinary tract infection
- Decreasing certain activities that cause SUI
- Efficacious following RP to allow quicker return of continence

**FOLLOW-UP**

- Patient Monitoring: Following surgical or medical treatments patients should be followed with standardized questionnaires, such as the International Consultation on Incontinence Questionnaire Short Form.
- Patients may also be followed with 1-hr or 24-hr pad weight testing, but this can be burdensome to obtain regularly in the office.
- Self-reported pad counts are easier to obtain, but not as accurate as a pad weight test.
- No routine labs or imaging are required unless complicating factors in the initial history and physical were identified.

- Incontinence, Urinary, Adult Male
- Incontinence, Urinary, Following Radical Prostatectomy
- Incontinence, Sphincteric Deficiency
- ICD-10 (International Classification of Diseases, 10th Revision)
- Overactive Bladder (OAB)

**CODES**

- C90.32 Stress incontinence, male
- C91.03 Incontinence (female) (male)

**CLINICAL/SURGICAL PEARLS**

- SUI is uncommon in young men, but becomes more common with age as more patients are undergoing urologic procedures.
- Most effective treatments are surgical, though medical therapy may be helpful in men with mild incontinence.
- The artificial urinary sphincter (AUS) remains the gold standard procedure for male SUI, however urethral slings are now commonly used with success approaching that of the AUS with proper patient selection.
STROKE (CVA), UROLOGIC CONSIDERATIONS
Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

GENERAL PREVENTION
- Stroke prevention measures
  - Smoking cessation
  - Blood pressure control
  - Cholesterol control
  - Diabetic control
  - Atrial fibrillation therapy in older women
  - Identify and control arterial fibrillation
  - Balanced diet and exercise
  - Low-dose aspirin if appropriate

DIAGNOSIS
- Based on diagnosis of CVA
- Evaluate for previous or underlying urologic issues or complaints
- Obtain medication history
- Detailed past surgical history

PHYSICAL EXAM
- Abdominal exam for bladder distention
- Neurologic exam (usually already done by primary team during initial diagnosis)
- Digital rectal exam (DRE) to evaluate rectal tone and prostate size in males
- Pelvic exam in females

DIAGNOSTIC TESTS & INTERPRETATION
- Urinalysis with or without urine culture as clinically appropriate
- Cystourethrogram to evaluate renal function
- Postvoid residual bladder scan
- Abdominal imaging
  - Renal/bladder ultrasound
  - KUB

Diagnostic Procedures/Surgery
- Voiding/fill/void studies
  - Bladder capacity
  - Daily weights
- Urodynamic studies: Should not be performed until stability in neurologic symptoms following stroke (not immediately)
  - Typically 3–6 mo following stroke
  - Evaluate bladder function and detrusor function vs. bladder outlet obstruction
  - May be used for surgical guidance and management if necessary

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Urinary Retention (see Section I “Urinary Retention, Adult Male,” “Urinary Retention, Adult Female”)
  - Urge incontinence
  - Stress incontinence
  - Mixed incontinence
  - Low bladder compliance resulting in overflow incontinence

TREATMENT
GENERAL MEASURES
- General stroke rehabilitation interventions (3)
  - Physical therapy
  - Occupational therapy
  - Initially and short term
    - Urinary bladder dysfunction with Foley catheter vs. clean intermittent catheterization (CIC)
  - Long term
    - CIC, Foley or suprapubic catheter for urinary retention and elevated post-void residuals
    - Caution to avoid long-term indwelling urethral catheter to avoid risk of bladder neck erosion or urethral injury
    - Bladder overactivity
    - Behavioral modifications regarding voiding
    - Use medication therapy below

MEDICATION
First Line
- Antimuscarinics or α1 blockers: Decrease detrusor overactivity (DO) that is demonstrated as urinary frequency and urgency
  - α1 antagonists
  - Side effects
    - Dry mouth, blurred vision, confusion
    - Use cautiously in geriatric patients secondary to potential central nervous system effects

Second Line
- α1-blockers for prostatic hyperplasia and retention related to BPH if necessary
- 5α-reductase inhibitors for BPH especially in those men with large prostate glands
STROKE (CVA), UROLOGIC CONSIDERATIONS

SURGERY/OTHER PROCEDURES
- Suprapubic catheter placement if long-term urinary retention
- Intravesical Botulinum toxin injections for DO
  - Temporary effect and may require patients to perform CIC
- Neuromodulation
  - Transurethral resection of prostate if concomitant BPH with clinical obstruction
- Urinary diversion

ADDITIONAL TREATMENT RADIATION THERAPY
- Additional Therapies
- Psychological support and re-enforcement
- Complementary &Alternative Therapies
  - Absorbent pads and products
  - Pelvic floor physical therapy with or without biofeedback
  - Acupuncture

ONGOING CARE

PROGNOSIS
- Health-related quality of life is impaired in general those with urgency incontinence post neurologic event (481)
- Urinary symptom outcome is proportional to the extent of resolution of other stroke sequelae
  - Those who resolve cognitive and/or motor function often resolve urinary issues

COMPLICATIONS
- Short term
  - Acute renal failure if acute urinary retention
  - Urinary tract infection if not draining bladder appropriately
- Long term
  - Renal dysfunction and possible renal failure
  - Urinary tract infections—recurrent
  - Decreased quality of life
  - Depression

FOLLOW-UP

PATIENT MONITORING
- Detrusor overactivity (DO): yearly checkups, medication monitored
- Neuromodulation and performing CIC
  - Evaluate renal function with yearly (or more often if clinically indicated) creatinine and renal ultrasound
  - Urodynamic evaluation for significant change in clinical symptoms
  - If revolving catheter dependent, needs regular cystoscopy to visualize bladder and monitor for cancer or stones
  - Increased risk of bladder cancer is secondary to chronic foreign body in urinary tract

PATIENT RESOURCES

CODES

ICD9
- 434.91 Cerebral artery occlusion, unspecified with cerebral infarction
- 788.29 Other specified retention of urine
- 788.38 Overflow incontinence

ICD10
- I63.9 Cerebral infarction, unspecified
- R33.8 Other retention of urine
- N39.490 Overflow incontinence

CLINICAL/SURGICAL PEARLS

- Important to determine residual urinary effects after near full recovery from stroke.
- Prior to operation, ensures stability of urinary function.

ADDITIONAL READING

- Detrusor Overactivity
- Neurogenic Bladder, General Considerations
- Urinary Retention, Adult Female
- Urinary Retention, Adult Male
- Urinary Retention, Pediatric
ASSOCIATED CONDITIONS

- BPH with urinary retention
- IC/PBS
- Prostatitis
- UTI
- Urinary retention

RISK FACTORS

- History of urinary tract infections (UTIs)
- BPH as it may cause urinary retention
- Urinary tract obstruction
- Immunosuppressed patients have increased susceptibility to infections
- Pelvic radiation treatment
- Chronic pain syndromes
- Stressful athletic activity

PHYSICAL EXAM

- Rectal exam: Tenesmus, swelling, or boggy prostate during palpation may indicate prostatitis
- Pelvic masses
- Pelvic exam: Palpable bladder suggests urinary retention
- Evidence of masses or blood with GI tract disease
- Pyuria, nitrite, and bacteria with infection
- Pyelonephritis
- Acute appendicitis
- Bladder perforation
- Prostatitis including acute bacterial, chronic nonbacterial, inflammatory and noninflammatory (NIH CP/CPPS III A and B)
- Prostatitis
- Urolithiasis
- Urethral stricture and IC/PBS (may see inflammatory lesions or Hunner’s ulcers)
- Acute urosepsis
- Acute urologic sepsis
- Urinary bladder perforation
- Urethral injury
- Urethral stricture
- Urolithiasis
- Urologic: CT cystogram
- Urologic: Urethral catheterization
- Urologic: Urinary REI
- Urologic: Urgency and stress urinary incontinence
- Urologic: Urinary tract infection
- Urologic: Urethral biopsy
- Urologic: Urinary retention
- Urologic: Urethral stricture
- Urologic: Urinary tract disease

IMAGING

- Plain x-ray: Important for evaluation of bowel, urachus, or foreign body
- CT pelvic: Useful for diagnosing GI etiology, urachus, or pelvic masses. Has no role in uncomplicated infections of the GU tract.
- US bladder: Assess posterior residual volume, calculi, or mass
- Pelvic US: Useful for genitourinary causes. Transvaginal US is best for uterine or ovarian evaluation.

DIAGNOSTIC PROCEDURES/SURGERY

- Cystoscopy:
  - Evaluate for bladder tumor, stone, outlet obstruction, urethral stricture and IC/PBS (may see inflammatory lesions or Hunner’s ulcers)
  - Comorbidized during acute GU infection such as UTI or prostatitis
  - Mears–Stamey 4-glass test for prostatitis evaluation
- Urodynamics:
  - Assess bladder capacity, bladder contraction, pressure, and outlet obstruction. Not indicated for acute suprapubic pain.

PATHOLOGIC FINDINGS

- Based on the specific entity

DIFFERENTIAL DIAGNOSIS

Interstitial cystitis/painful bladder syndrome  
BPH/urinary retention  

- Complicated UTI: Treat for 7–14 days with  
- Acute uncomplicated UTI in women (3,4):  
- The focus of this discussion is on urologic pathologic  

- First Line  
- r  
- r  
- Interstitial cystitis/painful bladder syndrome  
- BPH/urinary retention  

- Acute uncomplicated UTI in women (3,4):  
- Nitrofurantoin monohydrate/macrocrystals  
- Trimethoprim–sulfamethoxazole (160/800 mg  
- Antibiotics empirically for 2 wk. If cultures are  
- Culture-specific antibiotics.  
- Risk factors that make a UTI complicated include:  
- Indwelling catheter  
- Male sex  
- Functional or anatomical abnormality of the  
- Prophylaxis:  
- Antibiotics empirically for 2 wk. If cultures are  
- BPH/Urinary retention  
- Bladder calculi  
- Often require surgical removal. Medical therapy  
- Transurethral resection of prostate or other  
- Superficial tumors:  
- TURBT  
- Invasive tumors: Radical cystectomy with urinary  

- Second Line  
- SURGERY/OTHER PROCEDURES  
- • BPH/Urinary retention  
- • Transurethral resection to relieve acute  
- obstruction; if unable to perform then suprapubic  
- catheterization should be considered.  
- • Transurethral resection of prostate or other  
- ablative procedure (laser, microwave) if  
- appropriate.  
- • Bladder calculi:  
- • Remove transurethraly and fragment manually  
- with lithotrite or with Holmium laser  
- • Open cystolithotomy rarely needed  
- • IC/PBS  
- - 2nd-line treatment includes manual physical  
- therapy techniques that resolve pelvic, abdominal  
- and hip muscular trigger points, and lengthen  
- muscle contractions.  
- • Antispasmodics, cholinergic, hydroxyurea or pentam  
- polysulphone may be used as 2nd-line oral  

- Ongoing Care  
- Patient monitoring and follow-up is dependent on  
- the specific pathologic process.  
- Assessment of postobstructive diuresis following  
- relief of urinary obstruction includes measurement  
- of serum electrolytes.  
- Urine culture following treatment of complicated  
- UTI should be performed to ensure adequate treatment.  
- This is not needed for uncomplicated UTI in women.  

- Second Line  
- SUPRAPUBIC PAIN, GENERAL CONSIDERATIONS  

- Treatment  
- • The focus of this discussion is on urologic pathologic processes.  
- • Some common urologic conditions and interventions are noted below. Other conditions are beyond the scope of this section.  

- Medication  
- First Line  
- • Acute uncomplicated UTI in women (3,4):  
- • Nitrofurantoin monohydrate/macrocrystals  
- (100 mg twice daily for 5 days is appropriate due to  
- minimal resistance and propensity for collateral  
- damage)  
- • Trimethoprim–sulfamethoxazole (160/800 mg  
- [1 double-strength tablet] twice daily for 3 days)  
- given its efficacy in numerous clinical trials.  
- • Complicated UTI: Treat for 7–14 days with  
- culture-specific antibiotics.  
- • Risk factors that make a UTI complicated include:  
- • Indwelling catheter  
- • Immunosuppression  
- • Male sex  
- • Functional or anatomical abnormality of the  
- urinary tract  
- • History of urinary tract surgery  
- • Prophylaxis:  
- • Antibiotics empirically for 2 wk. If cultures are  
- positive or the patient has improved clinical  
- symptoms then continue antibiotics for 4–6 wk.  
- Antibiotics with excellent prostatic penetration  
- can be considered for uric acid stones.  
- • Alpha-blockers, such as tamsulosin, may be used.  
- • Alpha-blockers, such as tamsulosin, may be used.  
- • Bladder calculi  
- • Often require surgical removal. Medical therapy  
- can be considered for uric acid stones.  
- • Interstitial cystitis/painful bladder syndrome  
- (IC/PBS) (5)  
- • 1st-line treatment is behavioral modifications,  
- counseling and stress management, and coping  
- techniques.  
- • 2nd-line treatment includes manual physical  
- therapy techniques that resolve pelvic, abdominal  
- and hip muscular trigger points, and lengthen  
- muscle contractions.  
- • Antispasmodics, cholinergic, hydroxyurea or pentam  
- polysulphone may be used as 2nd-line oral  

- Other:  
- • Trauma  
- • Sexual abuse  
- • Osteitis pubis  
- • Abdominal wall myofascial pain  
- • In athletics (2):  
- • Sports hernia (athletic pubalgia, Sportsman’s  
- hernia)  
- • Adductor strain  
- • Muscle tears  
- • Avulsion injuries  
- • Stress fractures.  
- • Tears of acetabular labrum  

- Follow-up  
- Assessment of postobstructive diuresis following  
- relief of urinary obstruction includes measurement  
- of serum electrolytes.  
- Urine culture following treatment of complicated  
- UTI should be performed to ensure adequate treatment.  
- This is not needed for uncomplicated UTI in women.  

- Prognosis  
- Good prognosis with treatment of a clearly identified  
- problem. Patients with IC/PBS often have a chronic  
- course with flares that can last days to weeks to  
- months. These patients require a multimodal  
- treatment approach.  

- Follow-up  
- Patient Monitoring  
- • Patient monitoring and follow-up is dependent on  

- Codes  
- ICD9  
- • 592.9 Urinary calculus, unspecified  
- • 592.9 Urinary tract infection, site not specified  
- • 789.09 Abdominal pain, other specified site

- Diagnosis and Initial Management. Am Fam  
- 3. Wagnerlehner PM, Wurth P, Petket G.  
- Antimicrobials in uncomplicated infections.  
- 4. Hummers-Pradier E, Kochen MW. Urinary tract  
- infections in adult general practice patients. Br J  
- 5. Feudale SS, Moster DT, Bhadra AR. Recognition  
- and management of nonrelaxing pelvic floor  

- Clinical/Surgical Pearls  
- • Multiple organ systems can cause suprapubic pain  
- including urologic, gastrointestinal, gynecologic,  
- neurovascular and other rare causes.  
- • Bacterial cystitis typically causes a sharp and  
- stabbing pain that is worse at the end of micturition.  
- This is secondary to inflammation of the urethra.  
- • Acute urinary retention causes suprapubic pain by  
- overdistention of the bladder.  
- • CT imaging can be useful for diagnosing (i)  
- stricture, urethritis or pelvic masses, but CT has  
- no role in uncomplicated infections of the GU  
- tract.  
- • Cystoscopy can be used to evaluate for bladder  
- tumors, stone, outlet obstruction or urethral  
- stricture.  
- • 1st-line treatment for interstitial cystitis/painful  
- bladder syndrome (IC/PBS) involves behavioral  
- modifications, counseling and stress management  
- and coping techniques.
SYPHILIS
John L. Phillips, MD, FACS
Dawdu Lankford, MD, MPH

DESCRIPTION
- "Syphilis", coined by Fracastoro in 1500s
- Describes infection by the spirochete Treponema pallidum, 1st discovered in 1905 by Hoffman

RISK FACTORS
- Other sexually transmitted conditions
- "Syphilis" coined by Fracastoro in 1500s

ASSOCIATED CONDITIONS
